Chronology of the Swine Flu Pandemic: A Global Vaccination Project in 2009-2010.
A collection of articles, documents, news, and remarks on history of the Global Vaccination Project which was attempted to organize in 2009-2010. – RemembeЯ, 2024-2025, P. 2294.

Disclaimers

This Collection was compiled by Dr. Mikhail Teppone.

It was prepared in the course of research on Swine Flu Pandemic which was declared in 2009. The need for this collection is due to the fact that many web pages with the information related to the history of the 'Swine Flu Pandemic' and 'Global Vaccination Project' have been lost or removed from the original web-sites (see Chapter 19) and were preserved only in the web archive.

Another reason for preparing this collection is that historical facts published not at the scientific sources but at news platforms are usually forgotten and become inaccessible for further research.

The Collection has been prepared for research and education purposes to encourage further studies related to influenza pandemics that have occurred in the XXI century.

The Collection includes information that was found in the public domain.

The Compiler declares there is no conflict of interests or any financial interest.

Jefferson: It's true that influenza viruses are unpredictable, so it does call for a certain degree of caution. But one of the extraordinary features of this influenza – and the whole influenza saga – is that there are some people who make predictions year after year, and *they get worse and worse*.

None of them so far have come about, and these people are still there making these predictions. For example, what happened with the bird flu, which was supposed to kill us all? Nothing. But that doesn't stop these people from always making their predictions. *Sometimes you get the feeling that there is a whole industry almost waiting for a pandemic to occur*. [A Whole Industry is Waiting for a Pandemic. – Spiegel International, 21 July 2009]

No Cure For That Cold?

By Mary Jo Takach

New York

THE common cold is like the weather — everybody talks about it but no one can do much about it.

Nearly 26 years ago Britain's Medical Research Council set up a unit at Harvard Hospital, Salisbury, to study common colds. In the beginning, in England, as in the United States, the major research was to identify the cause of the common cold. The study of viruses was young and scientists were hopeful that only one or two caused the common cold.

Volunteers Exposed

The original viruses were identified by exposing volunteers to them and seeing what happened. The volunteers would be inoculated with potentially infectious viruses by placing a few drops of liquid containing them into the nose and if any of them developed colds this would indicate that virus had been present in the inoculus, explains Dr. Sylvia Reed of the cold unit's research staff.

Today, the number of viruses is no longer of interest. "It is now known that there are more than 90 serotypes of rhinoviruses, which do not cross-immunize against one another," Dr. Reed says. "Furthermore, a new group of viruses has also been isolated. These are called human coronaviruses and they also cause typical colds."

Dr. James Spray of the National Center for Disease Control in Atlanta, Ga., estimates that there are at least 200 cold viruses which cause Americans to lose 47 million workdays and 65 million school days every year.

These viruses do not cross-immunize. This means each virus would need its own vaccine. In addition, vaccines cause antibodies in the bloodstream and cold viruses affect the outer linings of the nasal passages — just about as far away from the bloodstream as one can get in the body." Dr. Spray notes. Also, the immunity against a cold lasts for about two weeks.

Thus, researchers have decided it is just not worth the effort to develop 200 vaccines which would have to be given every two weeks or so. The U.S. National Institutes of Health (NIH) closed down its Board of Vaccine Development last year, deciding it was a waste of time and money. The British equivalent is still flourishing although the trend of its research has changed radically.

There are at least 200 cold viruses

Volunteers, however, still enroll in the British program for 10 days. Only healthy people aged 18 to 50 are accepted and they are isolated in pairs or threes in comfortable apartments. The only people the volunteers meet other than their "flatmates" are the doctor, nurse and virologists, who are all gowned and masked.

Many of the volunteers are students, nurses, married couples or groups of housewives who can enjoy a relaxing holiday without expenses and with a bit of pocket money. Only about a third come down with a cold. Some actually return for another "vacation."

"At present," Dr. Reed explains, "the volunteers assist in two main research topics." One is assessing the activity in man of antiviral drugs. The other is testing influenza vaccines.

"At Salisbury, drugs which are known to be active against respiratory viruses in test tubes and which have satisfactorily completed their toxicology testing can be assessed for activity against experimental infections of volunteers using rhinoviruses, coronaviruses or attenuated influenza viruses," Dr. Reed says.

Possible Drugs

There are several drugs, according to Dr. Donald D'Alessio, an assistant professor of preventive medicine at the University of Wisconsin, which show some tendency to kill viruses the way antibiotics kill bacteria. "We have tested several compounds which showed activity in tissue against a group of viruses. Unfortunately, in humans the activity of these drugs is marginal."

When a specific compound does not work, researchers then try different derivatives of the compound in hope that one of these will prove stronger. As of yet, Dr. D'Alessio says, there has been no compound that shows itself to be "hot stuff," despite recent reports of one that has given some positive results in animal tests.

Flu to the Starboard! Man the Harpoons!
Fill 'em With Vaccine! Get the Captain! Hurry!

The New York Times, Feb. 13, 1976, p. 32
https://www.nytimes.com/1976/02/13/archives/flu-to-the-starboard-man-the-harpoons-fillem-with-vaccine-get-the.html

World-wide epidemics, or pandemics, of influenza have marked the end of every decade since the 1940's – at intervals of exactly eleven years 1946, 1957 and 1968. A perhaps simplistic reading of this immediate past tells us that 11 plus 1968 is 1979, and urgently suggests that those concerned with the public health had best plan without further delay for an imminent natural disaster.

Since the virus of influenza was first isolated in 1933, it has been measured, dissected and chemically analyzed with the assumption that its tiny particle holds the secret of its unique ability to persist into the twentieth century as the last great plague of man. In truth, the influenza virus particle will reveal the secret of its unusual mutability when the function of its genes and proteins can be understood.

The basic structure of the virus is now known, its proteins and genes counted and numbered and subject to deliberate laboratory manipulation, yet we have no answer to its predictable disappearance every ten years and its periodic replacement by new mutants to which the whole world is susceptible.

Reasonably effective vaccines for influenza have been available for thirty years, but not even recent pandemics have been significantly influenced by human intervention. Whenever pandemic influenza next appears, we must improve upon our well-intentioned but uncoordinated individual efforts of the past that have resulted in ambiguous advice to the public and inadequate production and maldistribution of vaccines.

The initial introduction in 1968 of the currently circulating Hong Kong subtype of influenza virus witnessed within the United States alone the occurrence of more than 50 million illnesses and 19,000 influenza-associated deaths (and 1968 was not our worst pandemic year). The economic burden of such a disaster is not easily Calculated but in 1968-69 approached $4 billion if losses in earnings are added to total medical costs.

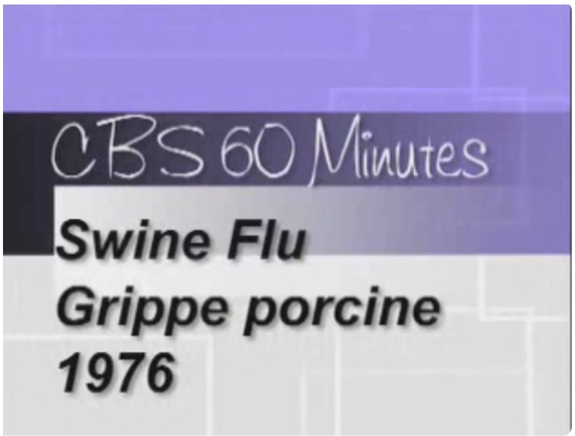
If, then, we accept pandemic influenza as a disaster and are concerned about its apparent predictability, what can be done about the predictable disaster of circa 1979? Although hardly as predictable as the tides, the recurrence of pandemics is predictable, if the record of the last 400 years is any guide to the future.

Much can be done without a single new scientific development. Our present vaccine policy is not carried out in practice. This policy recommends the preferential immunization of the estimated 45 million Americans unusually susceptible to influenza complications (pneumonia and death) even in interpandemic years.

But only about 20 million doses of vaccine are produced annually, and of this amount less than half reaches the high-risk population.

A central advisory commission should be established to coordinate the influenza-related research activities of the National Institute for Allergy and Infectious Diseases, the vaccine regulatory functions of the Bureau of Biologics of the Food and Drug Administration, and the epidemiological surveillance and public health advisory functions of the Center for Disease Control, to insure adequate production of vaccine by the private sector and its appropriate distribution. Achievement of this objective may require governmental subsidizing of industry with the probability of occasional overproduction of vaccine – but discarded vaccine should be weighed against discarded lives.

Although present vaccines do not produce lasting immunity, they are 70 percent to 90 percent effective for about one year. These vaccines have never been systematically or widely used during pandemics. If only individuals abnormally susceptible to fatal complications (those over 65 years of age and those with cardiac or pulmonary disease) were selectively immunized, many of the predictable thousands of deaths and millions of illnesses could be prevented.



Recent basic research has already yielded practical dividends in enhancement of vaccine production by the use of genetically modified viruses – thus shortening the production lag responsible, in part, for past vaccine shortages in pandemic years.

Meanwhile, research on new live virus vaccines as well as basic studies should be accelerated so that these and other new approaches to the control of pandemic influenza can be tested when pandemic influenza, the predictable natural disaster, next strikes.

The Swine Flu Affair. Decision-Making on a Slippery Disaese

Washington (DC): National Academies Press (US); 1978, 189 p. PMID: 25032342
https://www.ncbi.nlm.nih.gov/books/NBK219606/ // https://pubmed.ncbi.nlm.nih.gov/25032342/

Summaru and Comments

In winter 1976, it was cold on the East Coast of the United States. By mid-January, many of the recruits serving in the military at Fort Dix had "colds." The patients were offered hospitalization; one of them, David Lewis, refused hospitalization, continued training, and died suddenly.

On February 20, 1976, the New York Times published an article by scientific columnist Harold Schmeck stating that a recently discovered virus was probably the cause of the 1918-1919 epidemic.

On March 24, 1976, after discussing the events at Fort Dix, US President Gerald Ford announced a plan to vaccinate 200 million Americans against the swine flu virus. To carry out the program of total vaccination, J. Ford asked the US Congress for 135 million dollars, and later received the support of both chambers.

Vaccination began on October 1, but was suspended on December 16, 1976, due to an increasing number of various complications, including Guillain-Barré syndrome and deaths. In two and a half months, more than 40 million Americans received the vaccine.

As it turned out, ***there was no epidemic of swine flu*** and there was no need for vaccination. Human lives and huge funds were wasted. It was a trial balloon for future universal vaccination projects. No one has been held accountable for this crime.

Biology is destiny. "Though the years have been unkind to Sigmund Freud's thought, that notion sounds fresher now than when he said it. In the 1950s the threads of destiny were given form when Francis Crick and James Watson elucidated the double-helix structure of DNA. In the 1960s the language of genes, in which the messages stored on DNA are written, was translated; biology, and much else, began to change. Genes are blamed for everything from cancer to alcoholism. People worry about being made ineligible for jobs because of disease susceptibilities they never knew they had; fetuses are aborted because of faults in their genes; criminals are defined by the bar-codes of their genetic fingerprints. ...

APRIL 25TH 1992

Changing your genes

"BIOLOGY is destiny." Though the years have been unkind to Sigmund Freud's thought, that notion sounds fresher now than when he said it. In the 1950s the threads of destiny were given form when Crick and Watson elucidated the double-helix structure of DNA. In the 1960s the language of genes, in which the messages stored on DNA are written, was translated; biology, and much else, began to change. Genes are blamed for everything from cancer to alcoholism. People worry about being made ineligible for jobs because of disease susceptibilities they never knew they had; fetuses are aborted because of faults in their genes; criminals are defined by the bar-codes of their genetic fingerprints.

At first glance, genetic therapy—the nascent art of giving sick people new genes to alleviate their illness—looks like the apotheosis of this trend towards reducing human life to a few short sequences of DNA. But although its advent means people will be talking in the language of genes even more than they already do, the way they talk will change. They will not be passively reading out the immutable genetic lore passed down from generation to generation. They will not be receiving orders; they will be giving them. The birth of genetic therapy marks the beginning of an age in which man has the power to take control of his genes and make of them what he will.

New promises, new threats, old answers

At the moment, gene therapy is a small field on the fringes of medicine and biotechnology. Genes carry descriptions of proteins, the molecules that do most of the body's work; if someone is missing a gene, they will be missing a protein, and may thus suffer a deficiency or disease. If a gene or set of genes runs amok, cancer can result. The gene-therapists aim to provide the body with genes to make good its deficiencies and problems. If their field had grown as fast as the stacks of ethical reports and regulatory procedures that surround it, it would already be big business. As it is, after years of discussion, it is only now starting to blossom. Therapies are being tried on people around the world (though in tiny numbers) and new ways of delivering genes are being devised (see pages 95-97). A torrent of raw material for tomorrow's therapies is flowing from the human ge-

the drug is being made inside the body. There already exist sets of rules for trying out drugs. The question of the drug's provenance is of secondary importance, as long as its manufacture can be shown to be safe. Experimental gene therapy has satisfied regulators on that count, so far.

"So far", though, is only the beginning. Beyond today's gene therapy, which is a specialised form of medicine not that dissimilar to others, lie far more controversial possibilities: changing genes for non-medical reasons, and changing genes wholesale in such a way that the new genes are passed on from generation to generation. At present, therapists aim at genes that are clearly villains, and the therapies last at most as long as the patient, and often only as long as a transient set of cells. But what of genes that might make a good body better, rather than make a bad one good? Should people be able to retrofit themselves with extra neurotransmitters, to enhance various mental powers? Or to change the colour of their skin? Or to help them run faster, or lift heavier weights?

Yes, they should. Within some limits, people have a right to make what they want of their lives. The limits should disallow alterations clearly likely to cause harm to others. Even if the technology allowed it, people should not be allowed to become psychopaths at will, or to alter their metabolism so that they are permanently enraged. Deciding which alterations sit in this forbidden category would have to be done case by case, and in some cases the toss may be passionately argued. But so it is with all constraints on freedom. Minimal constraint is as good a principle in genetic law as in any other.

People may make unwise choices. Though that could cause them grief, it will be remediable. That which can be done, can be undone; people need no more be slaves to genes they have chosen than to genes they were born with. To keep that element of choice, however, one thing must be out of bounds. No one should have his genes changed without his informed consent; to force genetic change on another without his consent is a violation of his person, a crime as severe as rape or grievous bodily harm. There may be subtle social pressures to choose certain traits; but there is often social pressure for all sorts of things, and it does not deny the subject free will.

HOUSE OF COMMONS
CHAMBRE DES COMMUNES
CANADA

Forced Vaccinations coming to Canada: MP Speaks out Against Bill C-42

A rare breed: Bloc Quebecois MP Mario Laframboise in the House of Commons December 3, 2001 speaks out against the Orwellian powers of forced vaccination coming to Canada via Bill 42.

House of Commons, Canada, 3 December 2001

https://web.archive.org/web/20090917004221/http://www.natural-person.ca/pdf/Forced_Vaccinations_coming_to_Canada.PDF

Global Justice Network, Vancouver, BC:

Bill C-42(R), called the Public Safety Act (or by others the New and Improved War Measures Act), amends numerous other Acts of Canada including The Department of Health Act, the Quarantine Act, the Food and Drug Act, and the Hazardous Products Act among others. The Bill has been tabled as part of new anti-terrorism legislation, along with Bill C-35, C-36 (Note: To give new interim powers to the various Ministers in charge of the various Acts; powers that have previously been in the hands of the courts, who have an obligation to respect the rule of law and consider impartially the rights of Canadians under the Charter of Rights and Freedoms).

The potential effect of such interim powers were brought up by Bloc Quebecois **MP Mario Laframboise** in the House of Commons December 3, 2001:

"I can perhaps try to explain, to help Quebecers listening to us to better understand the new powers that would be given to the Health Minister. It is quite simple:

11.1 (1) The Minister may make an interim order that contains any provision that may be contained in a regulation made under section 11 if the Minister believes that immediate action is required to deal with a significant risk, direct or indirect, to health or safety. Hence, by way of an interim order, a new power has been given to the Health Minister. In the case of the anthrax vaccine or the protective inoculation, this power would have entailed the Minister to give his officials the power to buy the necessary vaccine and to compel every Canadian to receive it. These new dispositions all give more powers and this is what makes it so serious. It is not done simply by giving the minister more powers, because we do not simply give him more powers, we tell him that now An interim order is exempt from the application of sections 3, 5 and 11 of the Statutory Instruments Act.

This means that the minister could adopt interim orders for all sorts of emergency purposes and be exempt from the application of sections of the Statutory Instruments Act. And I am not talking about any old section, either. I will read a part of section 3, which would no longer apply to the Minister of Health in the case of interim orders. This section states:

3. (1) Subject to any regulations made pursuant to paragraph 20(a), where a regulation-making authority proposes to make a regulation, it shall cause to be forwarded to the Clerk of the Privy Council three copies of the proposed regulation in both official languages.

Now, it would no longer be necessary to send them in both official languages. I read on:

(2) On receipt by the Clerk of the Privy Council of copies of a proposed regulation pursuant to subsection (1), the Clerk of the Privy Council, in consultation with the Deputy Minister of Justice, shall examine the proposed regulation to ensure that

(a) it is authorized by the statute pursuant to which it is to be made;

(b) it does not constitute an unusual or unexpected use of the authority pursuant to which it is to be made;

(c) it does not trespass unduly on existing rights and freedoms and is not, in any case, inconsistent with the purposes and provisions of the Canadian Charter of Rights and Freedoms If the Minister of Health is empowered to make interim orders, to purchase vaccines, of whatever kind, exempt from the application of the provisions of enabling legislation, he could very well acquire unacceptable vaccines, vaccines whose patents are held elsewhere. This is no problem. He could then require a group to be vaccinated without complying with the charter of rights and freedoms. All this is effective for 23 days. After 23 days, the regulation must be published.

If this does not infringe individual rights and freedoms, I do not know what they can be thinking. If the minister had all these powers, why write in black and white in a bill that, now, he will be able to make interim orders without the House or the usual regulatory procedure requiring him to meet the test of the Charter of Rights and Freedoms." [end of quote]

The entire text of this speech in the House of Commons can be obtained at:
https://web.archive.org/web/20011224164309/http://www.parl.gc.ca/37/1/parlbus/chambus/house/debates/123_2001-12-03/HAN123-E.htm#Int-02138

This legislation is similar to the US Model State Emergency Health Powers Act. Health Scientist and Government Cover-up Investigator Dr. Len Horowitz claims in his article:
https://web.archive.org/web/20040401161443/http://www.prophecyandpreparedness.com/Articles.htm

Advances Totalitarian Legislation under Guise of Public Health:
Forced Drugging and Injections Are On The Horizon that forced vaccinations will soon be authorized in the United States under this proposed Act, a copy of which can be found at:
http://www.publichealthlaw.net/cgi-bin/dl_specs.cgi

One such amendment allows the Minister of Transport to declare temporary military zones for up to one year, without adherence to the Charter of Rights and Freedoms.

Section 260.1 (1) of this Bill reads:
"If it is necessary, in the opinion of the Minister, for the protection of international relations or national defence or security, the Minister, on the recommendation of the Chief of the Defence Staff, may, for the purpose of ensuring the safety or security of any person or thing, designate as a military security zone an area of land or water, a portion of airspace, or a structure or part of one, surrounding a thing referred to in subsection (2) or including it, whether the zone designated is fixed or moves with that thing. The zone automatically includes all corresponding water and land below the earth's surface."

This military zone may be designated to protect, includes property, a place or thing that the Canadian Forces have been directed to protect in order to fulfil a duty required by law. This could apply to the Kananaskis location of the upcoming G8 meeting, or any other area where the government wished to restrict legitimate protest and dissent. Under (4) The Canadian Forces may prohibit, restrict or control access to a military security zone; and under (5) A person found in a military security zone without authorization, and any animal, vehicle, vessel, aircraft or other thing under the person's control, may be forcibly removed by any authorized person, officer or non-commissioned member.

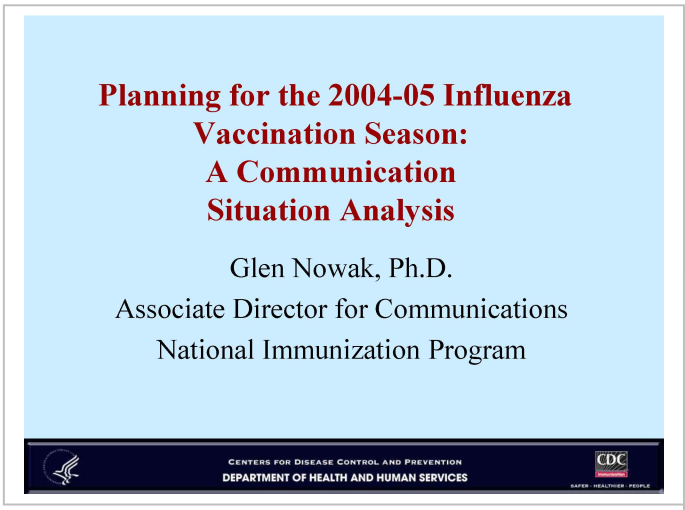
Furthermore, with the recent passage of Bill C-24 (otherwise known as the Police Brutality Act):
http://www.parl.gc.ca/common/bills_individual.asp?Language=E&Parl=37&Ses=1&Bill=C-24&BillType=government
which is an Act to amend the Criminal Code, public officers and their agents are now exempt from criminal charges under certain and very broad conditions. This Bill was passed by the Senate on December 6, 2001, despite a plethora of credible witnesses' testimony of the dangers of this Bill.

The Canadian Bar Association's (CBA) National Criminal Justice Section says sweeping changes in Bill C-24, will place law enforcement personnel and their agents above the law. "We are opposed to this profound change to the law out of respect for Canadian constitutional guarantees and the rule of law," says Heather Perkins-McVey, of Ottawa, National Criminal Justice Section Chair. The

legislation would allow police and even agents of the police to commit serious criminal acts without appropriate accountability, a move the CBA vigorously opposes. "Certainly, police must have the tools they need to do their job. However, creating a criminal exemption for police and their agents will create the possibility of a justice system prone to abuse and misuse of power," says Ms. Perkins-McVey. (See CBA Opposes Putting Police above the Law):

http://www.cba.org/news/releases/2001%5Freleases/2001%2D11%2D22%5Fpolice.asp

For instance, public officers who engage in or direct acts that would otherwise constitute an offense under the Criminal Code can now claim immunity under Section 25.1 if they were: engaged in the investigation of an offence under, or the enforcement of, an Act of Parliament & (i.e. Protection of foreign delegates under C-35 at an international G8 conference or acting under the interim orders of a Minister under C-42) and they believe on reasonable grounds that the commission of the act or omission & is reasonable and proportional in the circumstance. (This is left to the officer's discretion).



Although the public officer is normally required to obtain written authorization from a senior official, provision is made for the officer to undertake virtually any criminal offense on reasonable grounds that they could get such authorization. The evidence is mounting that democracy is now a farce in Canada, as it is in the United States, and that dictatorial power now resides in the Prime Minister and his select group of Ministers. Please take the time to write Senators and Members of Parliament.

Gordon F. Moran

Flu Vaccine Research: More Detailed Statistics Needed

Rapid response to:
Are US flu death figures more PR than science?

British Medical Journal, 8 December 2005, 331:1412 // 5 May 2006
doi: https://doi.org/10.1136/bmj.331.7529.1412

In his article, Peter Doshi contests the official government statistics for flu deaths, claiming the figures are too high. In his letter in response to this article, Prof. Marco Mamone-Capria writes that the situation is more complicated, regarding alleged flu deaths, than public health authorites would have the public believe. And he raises questions about how useful flu vaccines might be.

Some clarifications might be attained by means of more precise and detailed statistics. For example, during each year in which there is a promotional campaign for flu vaccines, there are four groups of persons:

1) Those who got their flu vaccine, and then got the flu.
2) Those who did not get a flu vaccine, and did not get the flu.
3) Those who did not get a flu vaccine, and got the flu.
4) Those who got their flu vaccine and did not get the flu.

Statistics for each of these groups would provide important information for scholars, and the public, in helping to arrive at informed opinions and decisions.

Along a similar line, it would seem likely and logical that many, if not most, of the alleged flu deaths are among persons in the over 65 age group. In fact, this group is a specific target during flu vaccine promotional campaigns.

How many of the alleged flu deaths in this age group include persons who got their flu vaccine in the wake of the public health officials' warnings and suggestions, and how many among persons who did not heed the warnings and did not get a flu vaccine?

Such statistics might provide important information relating to the relative urgency to get flu vaccines, and relating to how useful and effective flu vaccines really are.

EMERGING INFECTIOUS DISEASES

David J. Sencer, J. Donald Millar

Reflections on the 1976 Swine Flu Vaccination Program

CDC, Emerg Infect Dis., January 2006, 12 (1)
https://web.archive.org/web/20110512042827/http://www.cdc.gov/ncidod/eid/vol12no01/05-1007.htm

In 1976, 2 recruits at Fort Dix, New Jersey, had an influenzalike illness. Isolates of virus taken from them included A/New Jersey/76 (Hsw1n1), a strain similar to the virus believed at the time to be the cause of the 1918 pandemic, commonly known as swine flu. Serologic studies at Fort Dix suggested that >200 soldiers had been infected and that person-to-person transmission had occurred. We review the process by which these events led to the public health decision to mass-vaccinate the American public against the virus and the subsequent events that led to the program's cancellation. Observations of policy and implementation success and failures are presented that could help guide decisions regarding avian influenza.

- Edwin D. Kilbourne. Flu to the Starboard! Man the Harpoons! Fill with Vaccine! Get the Captain! Hurry! – New York Times, 13 February 1976 (1)
- Barack Obama and Richard Lugar. Grounding a Pandemic. – New York Times, 6 June 2005 (2)
- It has been 37 years since the last influenza pandemic, or widespread global epidemic, so by historic patterns we may be due for another. – New York Times, 17 July 2005 (3)

Kilbourne in 1976 (1) noted that pandemics of influenza occur every 11 years. Since the latest prediction in the New York Times (3) suggests that after 39 years we may be overdue for a pandemic, and since 2 US senators have recently headlined the possibility (2), that observation may become a political fact. Whether it becomes a scientific fact and a policy fact is yet to be seen. Some reflections on 1976 from 2 insiders' viewpoints may identify some of the pitfalls that public health policymakers will face in addressing potential influenza pandemics.

Swine Flu at Fort Dix

On February 3, 1976, the New Jersey State Health Department sent the Center for Disease Control (CDC) in Atlanta isolates of virus from recruits at Fort Dix, New Jersey, who had influenzalike illnesses. Most of the isolates were identified as A/Victoria/75 (H3N2), the contemporary epidemic strain. Two of the isolates, however, were not typeable in that laboratory. On February 10, additional isolates were sent and identified in CDC laboratories as A/New Jersey/76 (Hsw1N1), similar to the virus of the 1918 pandemic and better known as "swine flu."

A meeting of representatives of the military, the National Institute of Health, the Food and Drug Administration (FDA), and the State of New Jersey Department of Health was quickly convened on Saturday, February 14, 1976. Plans of action included heightened surveillance in and around Fort Dix, investigation of the ill recruits to determine if contact with pigs had occurred, and serologic testing of recruits to determine if spread had occurred at Fort Dix.

Surveillance activities at Fort Dix gave no indication that recruits had contact with pigs. Surveillance in the surrounding communities found influenza caused by the current strain of influenza, A/Victoria, but no additional cases of swine flu. Serologic testing at Fort Dix indicated that person-to-person transmission had occurred in >200 recruits (4).

In 1974 and 1975, 2 instances of humans infected with swine influenza viruses had been documented in the United States. Both persons involved had close contact with pigs, and no evidence for spread of the virus beyond family members with pig contact could be found (5).

The National Influenza Immunization Program

On March 10, 1976, the Advisory Committee on Immunization Practices of the United States Public Health Service (ACIP) reviewed the findings. The committee concluded that with a new strain (the H1N1 New Jersey strain) that could be transmitted from person to person, a pandemic was a possibility. Specifically, the following facts were of concern: 1) persons <50 years of age had no antibodies to this new strain; 2) a current interpandemic strain (A/Victoria) of influenza was widely circulating; 3) this early detection of an outbreak caused by A/New Jersey/76/Hsw1N1 (H1N1) provided an opportunity to produce a vaccine since there was sufficient time between the initial isolates and the advent of an expected influenza season to produce vaccine. In the past when a new pandemic strain had been identified, there had not been enough time to manufacture vaccine on any large scale; 4) influenza vaccines had been used for years with demonstrated safety and efficacy when the currently circulating vaccine strain was incorporated; 5) the military vaccine formulation for years had included H1N1, an indication that production was possible, and no documented adverse effects had been described.

ACIP recommended that an immunization program be launched to prevent the effects of a possible pandemic. One ACIP member summarized the consensus by stating "If we believe in prevention, we have no alternative but to offer and urge the immunization of the population." One ACIP member expressed the view that the vaccine should be stockpiled, not given.

Making this decision carried an unusual urgency. The pharmaceutical industry had just finished manufacture of the vaccine to be used in the 1976–1977 influenza season. At that time, influenza vaccine was produced in fertilized hen's eggs from special flocks of hens. Roosters used for fertilizing the hens were still available; if they were slaughtered, as was customary, the industry could not resume production for several months.

On March 13, an action memo was presented to the Secretary of the Department of Health Education and Welfare (DHEW). It outlined the problem and presented 4 alternative courses of action. First was "business as usual," with the marketplace prevailing and the assumption that a pandemic might not occur. The second was a recommendation that the federal government embark on a major program to immunize a highly susceptible population. As a reason to adopt this plan of action, the memo stated that "the Administration can tolerate unnecessary health expenditures better than unnecessary death and illness if a pandemic should occur." The third proposed course of action was a minimal response, in which the federal government would contract for sufficient vaccine to provide for traditional federal beneficiaries – military personnel, Native Americans, and Medicare-eligible persons. The fourth alternative was a program that would represent an exclusively federal response without involvement of the states.

The proposal recommended by the director of CDC was the second course, namely, for the federal government to contract with private pharmaceutical companies to produce sufficient vaccine to permit the entire population to be immunized against H1N1. The federal government would make grants to state health departments to organize and conduct immunization programs. The federal government would provide vaccine to state health departments and private medical practices. Since influenza caused by A/Victoria was active worldwide, industry was asked to incorporate the swine flu into an A/Victoria product to be used for populations at high risk.

Before the discussions with the secretary of DHEW had been completed, a member of his staff sent a memo to a health policy advisor in the White House, raising the specter of the 1918 pandemic, which had been specifically underemphasized in the CDC presentation. CDC's presentation highlighted the pandemic potential, comparing it with the 1968–69 Hong Kong and 1957–58 Asian pandemics. President Gerald Ford's staff recommended that the president convene a large group of well-known and respected scientists (Albert Sabin and Jonas Salk had to be included) and public

representatives to hear the government's proposal and make recommendations to the president about it. After the meeting, the president had a press conference, highlighted by the unique simultaneous appearance of Salk and Sabin. President Ford announced that he accepted the recommendations that CDC had originally made to the secretary of DHEW. The National Influenza Immunization Program (NIIP) was initiated.

The proposal was presented to 4 committees of the Congress, House and Senate authorization committees and House and Senate appropriation committees. All 4 committees reported out favorable legislation, and an appropriation bill was passed and signed.

The estimated budgeted cost of the program was $137 million. When Congress passed the appropriation, newspapers mischaracterized the cost as "$1.9 billion" because the $137 million was included as part of a $1.9 billion supplemental appropriation for the Department of Labor. In the minds of the public, this misconception prevailed.

Immediately after the congressional hearing, a meeting of all directors of state health departments and medical societies was held at CDC. The program was presented by CDC, and attendees were asked for comments. A representative from the New Jersey state health department opposed the plan; the Wisconsin state medical society opposed any federal involvement. Otherwise, state and local health departments approved the plan.

Within CDC, a unit charged with implementing the program, which reported to the director, was established. This unit, NIIP, had complete authority to draw upon any resources at CDC needed. NIIP was responsible for relations with state and local health departments (including administration of the grant program for state operations, technical advice to the procurement staff for vaccine, and warehousing and distribution of the vaccine to state health departments) and established a proactive system of surveillance for possible adverse effects of the influenza vaccines, the NIIP Surveillance Assessment Center (NIIP-SAC). (This innovative surveillance system would prove to be NIIP's Trojan horse.) In spite of the obstacles discussed below, NIIP administered a program that immunized 45 million in 10 weeks, which resulted in doubling the level of immunization for persons deemed to be at high risk, rapidly identifying adverse effects, and developing and administering an informed consent form for use in a community-based program.

Obstacles to the Vaccination Plan

The principal obstacle was the lack of vaccines. As test batches were prepared, the largest ever field trials of influenza vaccines ensued. The vaccines appeared efficacious and safe (although in the initial trials, children did not respond immunologically to a single dose of vaccine, and a second trial with a revised schedule was needed) (6). Hopes were heightened for a late summer/early fall kickoff of mass immunization operations.

In January 1976, before the New Jersey outbreak, CDC had proposed legislation that would have compensated persons damaged as a result of immunization when it was licensed by FDA and administered in the manner recommended by ACIP. The rationale given was that immunization protects the community as well as the individual (a societal benefit) and that when a person participating in that societal benefit is damaged, society had a responsibility to that person. The proposal was sent back from a staff member in the Surgeon General's office with a handwritten note, "This is not a problem."

Soon, however, NIIP received the first of 2 crippling blows to hopes to immunize "every man, woman, and child." The first was later in 1976, when instead of boxes of bottled vaccine, the vaccine manufacturers delivered an ultimatum – that the federal government indemnify them against claims of adverse reactions as a requirement for release of the vaccines. The government quickly capitulated to industry's demand for indemnification. While the manufacturers' ultimatum reflected the trend of increased litigiousness in American society, its unintended, unmistakable subliminal message blared "There's something wrong with this vaccine." This public misperception, warranted or not, ensured that every coincidental health event that occurred in the wake of the swine flu shot would be scrutinized and attributed to the vaccine.

On August 2, 1976, deaths apparently due to an influenzalike illness were reported from Pennsylvania in older men who had attended the convention of the American Legion in Philadelphia. A combined team of CDC and state and local health workers immediately investigated. By the next day, epidemiologic evidence indicated that the disease was not influenza (no secondary cases occurred in the households of the patients). By August 4, laboratory evidence conclusively ruled out influenza. However, this series of events was interpreted by the media and others as an attempt by the government to "stimulate" NIIP.

Shortly after the national campaign began, 3 elderly persons died after receiving the vaccine in the same clinic. Although investigations found no evidence that the vaccine and deaths were causally related, press frenzy was so intense it drew a televised rebuke from Walter Cronkite for sensationalizing coincidental happenings.

Guillain-Barré Syndrome

What NIIP did not and could not survive, however, was the second blow, finding cases of Guillain-Barré syndrome (GBS) among persons receiving swine flu immunizations. As of 1976, >50 "antecedent events" had been identified in temporal relationship to GBS, events that were considered as possible factors in its cause. The list included viral infections, injections, and "being struck by lightning." Whether or not any of the antecedents had a causal relationship to GBS was, and remains, unclear. When cases of GBS were identified among recipients of the swine flu vaccines, they were, of course, well covered by the press. Because GBS cases are always present in the population, the necessary public health questions concerning the cases among vaccine recipients were "Is the number of cases of GBS among vaccine recipients higher than would be expected? And if so, are the increased cases the result of increased surveillance or a true increase?" Leading epidemiologists debated these points, but the consensus, based on the intensified surveillance for GBS (and other conditions) in recipients of the vaccines, was that the number of cases of GBS appeared to be an excess.

Had H1N1 influenza been transmitted at that time, the small apparent risk of GBS from immunization would have been eclipsed by the obvious immediate benefit of vaccine-induced protection against swine flu. However, in December 1976, with >40 million persons immunized and no evidence of H1N1 transmission, federal health officials decided that the possibility of an association of GBS with the vaccine, however small, necessitated stopping immunization, at least until the issue could be explored. A moratorium on the use of the influenza vaccines was announced on December 16; it effectively ended NIIP of 1976. Four days later the New York Times published an op-ed article that began by asserting, "Misunderstandings and misconceptions... have marked Government ... during the last eight years," attributing NIIP and its consequences to "political expediency" and "the self interest of government health bureaucracy" (7). These simple and sinister innuendos had traction, as did 2 epithets used in the article to describe the program, "debacle" in the text and "Swine Flu Fiasco" in the title.

On February 7, the new secretary of DHEW, Joseph A. Califano, announced the resumption of immunization of high-risk populations with monovalent A/Victoria vaccine that had been prepared as part of the federal contracts, and he dismissed the director of CDC.

Lessons Learned

NIIP may offer lessons for today's policymakers, who are faced with a potential pandemic of avian influenza and struggling with decisions about preventing it. Two of these lessons bear further scrutiny here.

Media and Presidential Attention

While all decisions related to NIIP had been reached in public sessions (publishing of the initial virus findings in CDC's weekly newsletter, the Morbidity and Mortality Weekly Report (MMWR); New York Times reporter Harold Schmeck's coverage of the ACIP sessions, the president's press conference, and 4 congressional hearings), effective communication from scientifically qualified

persons was lacking, and the perception prevailed that the program was motivated by politics rather than science. In retrospect (and to some observers at the time), the president's highly visible convened meeting and subsequent press conference, which included pictures of his being immunized, were mistakes. These instances seemed to underline the suspicion that the program was politically motivated, rather than a public health response to a possible catastrophe.

Annex 11 of the draft DHEW pandemic preparedness plan states, "For policy decisions and in communication, making clear what is not known is as important as stating what is known. When assumptions are made, the basis for the assumptions and the uncertainties surrounding them should be communicated" (11). This goal is much better accomplished if the explanations are communicated by those closest to the problem, who can give authoritative scientific information. Scientific information coming from a nonscientific political figure is likely to encourage skepticism, not enthusiasm.

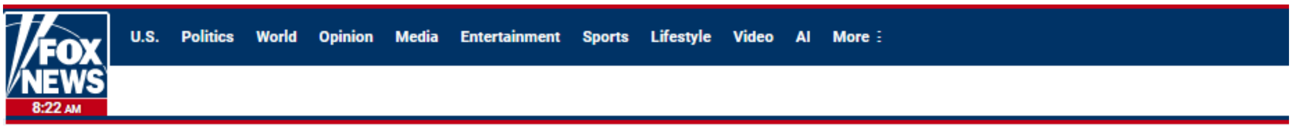
Neither CDC nor the health agencies of the federal government had been in the habit of holding regular press conferences. CDC considered that its appropriate main line of communication was to states and local health departments, believing that they were best placed to communicate with the public. MMWR served both a professional and public audience and accounted for much of CDC's press coverage. In 1976, no all-news stations existed, only the nightly news. The decision to stop the NIIP on December 16, 1976, was announced by a press release from the office of the assistant secretary for health. The decision to reinstitute the immunization of those at high risk was announced by a press release from the office of the secretary, DHEW. In retrospect, periodic press briefings would have served better than responding to press queries. The public must understand that decisions are based on public health, not politics. To this end, health communication should be by health personnel through a regular schedule of media briefings.

Decision To Begin Immunization

This decision is worthy of serious question and debate. As Walter Dowdle (12) points out in this issue of Emerging Infectious Diseases, the prevailing wisdom was that a pandemic could be expected at any time. Public health officials were concerned that if immunization was delayed until H1N1 was documented to have spread to other groups, the disease would spread faster than any ability to mobilize preventive vaccination efforts. Three cases of swine influenza had recently occurred in persons who had contact with pigs. In 1918, after the initial outbreak of influenza at Fort Riley in April, widespread outbreaks of influenza did not occur until late summer (13).

The Delphi exercise of Schoenbaum in early fall of 1976 (13) was the most serious scientific undertaking to poll scientists to decide whether or not to continue the program. Its main finding was that the cost benefit would be best if immunization were limited to those >25 years of age (and now young children are believed to be a potent source of spread of influenza virus!). Unfortunately, no biblical Joseph was there to rise from prison and interpret the future.

As Dowdle further states (12), risk assessment and risk management are separate functions. But they must come together with policymakers, who must understand both. These discussions should not take place in large groups in the president's cabinet room but in an environment that can establish an educated understanding of the situation. Once the policy decisions are made, implementation should be left to a single designated agency. Advisory groups should be small but representative. CDC had the lead responsibility for operation of the program. Implementation by committee does not work. Within CDC, a unit was established for program execution, including surveillance, outbreak investigation, vaccine procurement and distribution, assignment of personnel to states, and awarding and monitoring grants to the states. Communications up the chain of command to the policymakers and laterally to other directly involved federal agencies were the responsibility of the CDC director, not the director of NIIP, who was responsible for communications to the states and local health departments, those ultimately implementing operations of the program. This organizational mode functioned well, a tribute to the lack of interagency jealousies.



Decision-making Risks

When lives are at stake, it is better to err on the side of overreaction than underreaction. Because of the unpredictability of influenza, responsible public health leaders must be willing to take risks on behalf of the public. This requires personal courage and a reasonable level of understanding by the politicians to whom these public health leaders are accountable. All policy decisions entail risks and benefits: risks or benefits to the decision maker; risks or benefits to those affected by the decision. In 1976, the federal government wisely opted to put protection of the public first.

Dr Sencer was director of CDC from 1966 to 1977.
Dr Millar was director of NIIP in 1976.

Leavitt to Grant Waivers for Bird Flu Vaccine Makers

Foxnews, 13 February 2006
https://www.foxnews.com/story/leavitt-to-grant-waivers-for-bird-flu-vaccine-makers

Washington – The government won't wait for bird flu to hit U.S. shores before granting liability protections to vaccine manufacturers and others that make products needed to battle a pandemic.

Health and Human Services Secretary Mike Leavitt said Monday that the administration soon would enter into contracts for the bird flu vaccine, rapid tests to detect the virus, and technology that would make available vaccine go farther.

"At some point in that process, we'll need to deal with the issue of liability," he told reporters.

In December, Congress gave Leavitt the authority to grant liability waivers if a public health emergency exists.

Under the waivers, people injured by a vaccine against bird flu would have to prove willful misconduct to bring a claim for damages. Critics have said that such a high threshold would make it almost impossible for people injured by a drug to file a lawsuit.

Leavitt said it's possible that vaccine manufacturers would want the extra protections before conducting clinical trials.

"If you're a vaccine manufacturer, you're likely not going to want to move to that step unless you've got adequate liability protection." he said.

Bird flu has killed at least 88 people in Asia and Turkey since 2003, according to the World Health Organization. An additional two deaths from bird flu have been confirmed in Indonesia. Birds carrying the virus have also been detected in Italy, Greece and Nigeria.

Leavitt said there's no reason to think that H5N1 virus will stop its migration.

"At some point in time, there will be a wild bird that will be discovered (with the virus) in the United States," he said. "That in itself won't be an emergency. That is something we should expect."

If vaccine manufacturers have been given immunity from prosecution for making a toxic product, what incentive do they have to maintain minimum standards of quality control?

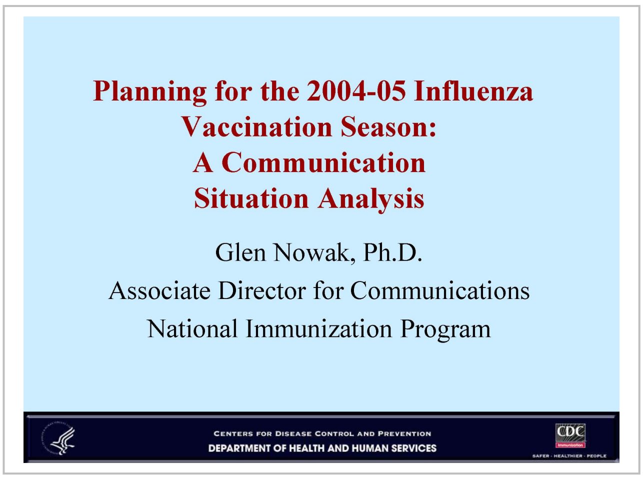
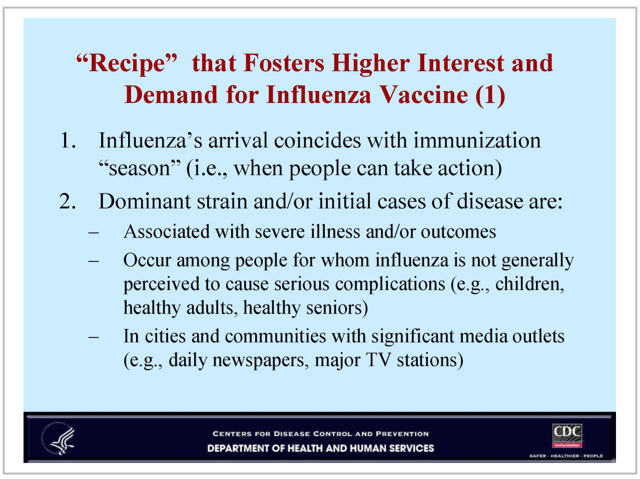
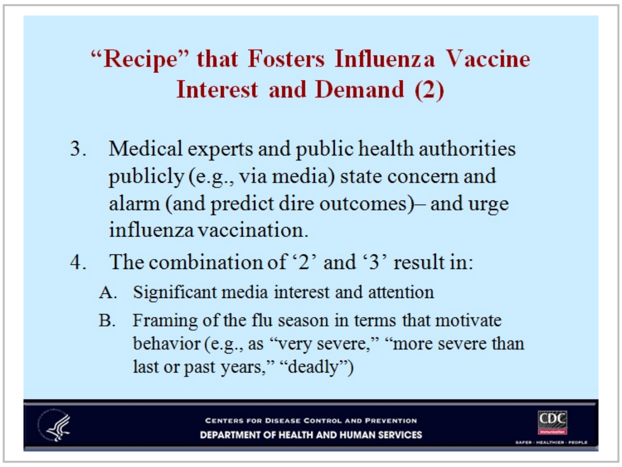
Viral Marketing: The Selling of the Flu Vaccine



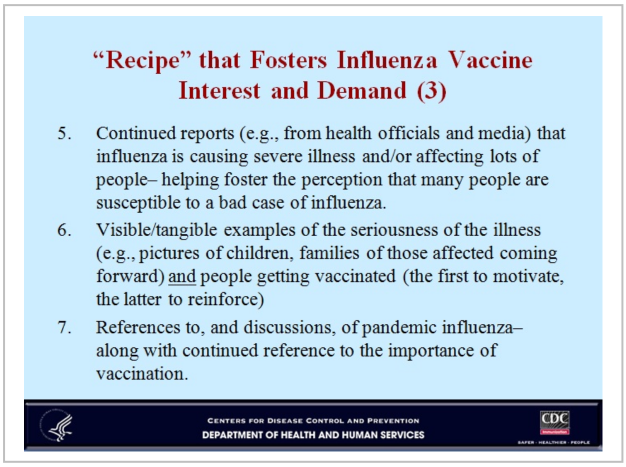
Harpers Magazine, March 2006
Lethbridge Herald, 7 November 2023 // 9 December 2020
https://lethbridgeherald.com/commentary/letters-to-the-editor/2020/12/09/ucp-needs-to-tighten-the-pandemic-rules/



[biff] ... *the following is copied from harper's magazine, 2/28/2006. the article is titled, "viral marketing" (the selling of the flu vaccine). It does not copy very well as the references to power point notes do not show as they do in the article. I say, history repeats, because we are suckers… We are made scared, insecure, too hopeful of govt and big corp, and suspicious of too many of the wrong things. good luck, sheeple.*



=> ref.: Harpers Magazine, March 2006



HARPER'S MAGAZINE

This "recipe," outlined in a PowerPoint presentation, is the U.S. government's public-relations strategy for selling Americans on flu shots. At the 2004 National Influenza Vaccine Summit, Glen, Nowak of the Centers for Disease Control and Prevention (CDC) used these slides to explain how certain messages generate buzz and drive demand. Indeed, the influenza virus has spawned a national industry of late, with President Bush himself asking Congress to fund a $7.1 billion flu "preparedness plan." But in the CDC's aggressive marketing of the shots, the agency has employed dubious statistics and questionable methods, leaving Americans less equipped than ever to gauge the threat rationally. The recipe, as Nowak revealed, relies on creating "concern, anxiety, and worry" – its main ingredient, in other words, is fear. See =>
https://web.archive.org/web/20040604044338/https://www.ama-assn.org/ama1/pub/upload/mm/36/2004_flu_nowak.ppt

Government officials and health experts following the recipe are instructed here to "predict dire outcomes." From a 2002 focus group, the CDC determined that death statistics in its fluprevention literature were "eye catching and motivating." Participants in the study believed "20,000 deaths was compelling, frightening" and "should be part of the headline." In 2003, the agency began announcing that the number of Americans killed each year by flu had surged to 36,000, an 80 percent increase that is now widely reported. Among all flu-prevention messages in the news during the week of 9/21/03, according to Nowak's presentation, "Flu kills 36,000 per year" appeared second most often, just behind "Doctors recommend/urge flu shot." But the 36,000 figure is actually a measure of "flu-associated" fatalities-almost exclusively among the elderly and infirm, whose deaths from other illnesses the CDC thinks might not have occurred without the flu. Records show that only 1,400 deaths a year are attributed to flu.

Another way to "motivate behavior," the recipe notes here, is to describe a flu season as "very severe," "more severe" than previous years, and "deadly" – all terms that had been used to frame the 2003-2004 threat. Yet that winter's flu was later ruled typical and "medium in terms of overall impact." The CDC's mortality figures, also presented as fact, are similarly misleading. Although many health experts contend that flu is a significant cause of wintertime mortality, other scientists argue that its role in these deaths is minor. This uncertainty can be seen on the government's list of the leading causes of death: at seventh place, with 65,681 annual fatalities, is "influenza and pneumonia." When separated out, however, flu is credited with fewer than 750 of the total. The CDC claims that more virulent flu strains and a growing elderly population led to the recent sharp climb in flu-associated deaths, but this too is.suspect. These factors did not cause a corresponding rise in recorded flu deaths, which actually fell 30 percent.

The CDC believes anything that encourages more people to get flu shots-even, as suggested in this step, spreading the notion that all of us could be in serious danger – will result in fewer deaths. But the efficacy of the flu vaccine 'is itself uncertain. Each year hundreds of clinically indistinguishable illnesses are diagnosed as flu, yet COC records show that the influenza virus causes only an eighth of these. It turns out that even the best shots have no effect on at least half the illnesses thought to be flu. Several recent studies have also called into question the fundamental justification for expanded vaccination. After looking at more than three decades of data, scientists at the National Institutes of Health last year concluded, "We could not correlate increasing vaccination coverage after 1980 with declining mortality rates in any age group." And because flu shots contain some level of toxic mercury, there is concern that for some the vaccine might do more harm than good.

Here the recipe emphasizes that the public must be made to grasp the "seriousness of the illness." When 50 million doses of vaccine suddenly became unavailable in 2004, Americans understandably panicked. Health centers were inundated with worried flu-shot seekers, price gouging was reported, and medical experts predicted a public-health "catastrophe." The CDC, with its knowledge of P.R., downgraded its scary portrayal of the flu to "an annoying illness" from which most people "will

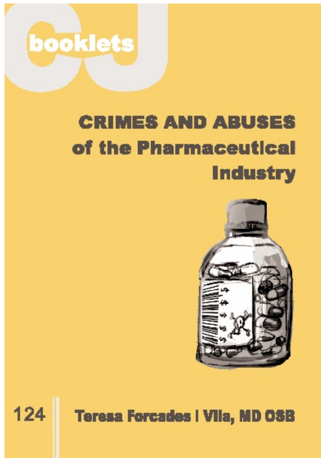
recover just fine." It stressed the protective benefits of regular hand washing. And once the alleged crisis abated, the agency returned to its strident communications plan. By the next fall, the CDC director was publicly stating that the flu is not "a benign illness. Many people don't appreciate that it can result in hospitalization, various complications. For about 36,000 people every year, death."

Demand for vaccine is up this year, a trend the CDC attributes in part to its repeated warnings about pandemic influenza. Such accounts of a looming plague are themselves perennial. In 1976 US, officials initiated a plan to vaccinate "every man, woman, and child" for an imminent pandemic of "swine flu." Yet a year later, swine flu had killed at most one person, whereas the vaccine is believed to have caused a debilitating illness. Alan Hinman, former director of the U.S. immunization program, drew what is exactly the wrong lesson from this fiasco: "that expansion to pandemic-level vaccination of the entire population would be much easier if there was an effective, stable, ongoing[flu] vaccination program." In this season's pandemic scare, Congress has responded to Bush's call by passing a bill that allows the government to confer blanket immunity from liability on makers of vaccines. As the wages of fear accrue to pharmaceutical companies, Americans are made into a captive market for vaccines of questionable worth.

[biff] ... Comments:

Just the minuses again – nothing to say….what do you not like in the harper's article? do not like truth that upsets one's glazed over view of reality?

... despite history being a constant with regard to absolute power residing not with the stupid masses, but with a small core of power and wealth brokers, here we are in the so-called age of information…and what do we find? powerless masses made insecure and frightened and suspicious by the owners of mass media and all things that constitute power and real wealth in our society. and, utter failure to be suspicious of the very things that require investigation and suspicion. govt and big corp must be transparent, but they are increasingly opaque; people must be free within the context of responsibility to each other's safety and freedom, but instead, we have been rendered increasingly transparent. it is backward, folks. whsitleblowers are bad; hushed people are good.



... the bigger joke is that there are the simple minded that see a more egalitarian society as totalitarian. and yet, here we are, under a corrupt and unsustainable economic system, ever more under the watchful eye of big brother and big corp, fearful mo f whatever the govt and big corp controlled media tell us to fear, and we think our freedom is not being whitewashed.

good luck, folks. gas prices about to explode…to pay for the latest covid expenses, most of which is lining big corp pockets. the cost of living is going to jump rather largely as a consequence. but fear and one's inability to face discomfort, and instead buy into a calming narrative that is bs, will keep the masses more passive than if there were military on every corner.

hoping i have got it mostly wrong, but history says no, and so do the facts of the day.

good health and luck to all. minus me to the hilt – my signing off gift.

Crimes and Abuses of the Pharmaceutical Industry

Translation: Gerarda Walsh and Cheryl Waschenko
Barcelona (Spain): Cristianisme I Justícia, 2006
https://archive.org/details/forcades-crimes-abuses

Contents

In the brief period from 2000 to 2003, *almost all the large pharmaceutical companies* went before state tribunals in the USA, *accused of fraudulent practices*.

Eight of these firms were fined over 2.2 billion dollars. Four of these eight companies – TAP Pharmaceuticals, Abbott, AstraZeneca and Bayer- admitted criminal responsibility for activities that put the lives and health of thousands of people at risk1.

What were these activities? And who bore the price? What causes pharmaceutical companies to behave in such a way? What actions have been taken in response to these abuses, and what actions still need to be taken? This booklet will examine the current strategies used by the pharmaceutical industry and the direct impact these strategies have on the way health and illness are defined and on which types of resources are available today to promote health and to prevent or cure disease.

Michael Day

Drug Industry Sponsorship. Who's funding WHO?

BMJ, 17 February 2007; 334:338-340
doi:10.1136/bmj.39119.519664.BE
https://www.ncbi.nlm.nih.gov/pmc/articles/PMC1801033/

WHO guidelines state that it will not accept money from drug companies, but how rigorous is it in enforcing this? Michael Day investigates

Serious questions have been raised about whether the World Health Organization is using patient groups as a conduit for receiving proscribed donations from the pharmaceutical industry. Email correspondence passed to the BMJ seems to show that in June 2006 Benedetto Saraceno, the director of WHO's department of mental health and substance abuse, suggested that a patient organisation accept $10 000 (£5000; €7000) from GlaxoSmithKline (GSK) on WHO's behalf. The sum was then to be passed on to WHO – ostensibly with the intention of obscuring the origins of the donation. GSK withdrew its offer of funding when it learnt that acceptance was conditional on obscuring its origin. However, the email exchange indicates that other sums of money originating from drug companies may have already been channelled to WHO through patient groups.

When asked about this correspondence, Dr Saraceno told the *BMJ* that his email to the patient organisation was “clumsily worded” and that he had “never intended to solicit donations from the pharmaceutical industry through” the patient organisation. In the email dated 16 June 2006, Dr Saraceno thanks Mary Baker of the European Parkinson's Disease Association (EPDA), for raising the $10 000 “requested by the WHO.” The money was to have funded a report on neurological diseases, including Parkinson's disease, for which GSK produces treatments.

Dr Saraceno then seems to advise Mary Baker on how to get round the WHO's rules forbidding drug industry funding. “Unfortunately,” he says, “WHO cannot receive funds from pharmaceutical industry. Our legal Office will reject the donation. WHO can only receive funds from Government agencies, NGOs, foundations and scientific institutions or professional organisations. Therefore, I suggest that this money should be given to EPDA and eventually EPDA can send the funds to WHO which will give an invoice (and acknowledge contribution) to EPDA, but not to GSK.”

He adds: “This is in line with what we have done so far with other contributions to the report which all are coming from other professional organisations,” – suggesting that less than transparent transactions were the norm for this fundraising operation.

WHO guidelines

According to paragraph 13 of the WHO's guidelines on interactions with commercial enterprises, which deals with cash donations, “WHO should avoid indirect collaboration (particularly if arranged by a third party acting as an intermediary between WHO and a commercial enterprise).” Paragraphs 15 and 16 of the guidelines state that funds may not be sought or accepted from commercial enterprises that have a direct commercial interest in the outcome of the project and that caution should be exercised even when the business has an indirect interest. And paragraph 27 says that for reasons of transparency, contributions from commercial enterprises must be acknowledged.

Richard Nicholson, editor of the Bulletin of Medical Ethics, said: “It would be very bad indeed if the WHO were trying to obtain money surreptitiously from drugs companies. Unfortunately it's also

under-funded, and sadly there's always going to be the temptation of senior officials who ought to know better than to accept such money. But they should remember that there's always a price attached to such funding.”

Even the senior GSK official who offered the money to the EPDA professes outrage at the secretive means by which WHO attempted to obtain the drug company grant. Alastair Benbow, vice president of GSK, withdrew the offer of funding went he learnt of Dr Saraceno's response to GSK's proposed donation. In an email to Mary Baker of 19 June 2006 he said: “Unless I am misreading something here it sounds like they [WHO] will accept funding from you but not from the industry. Worse than this, they will accept funding from you even if they know it originally came from us, in order to bypass their own rules. This is hypocritical in the extreme. It makes a complete mockery of attempts at transparency, which should be welcome, and which the WHO have called for.”

Some critics said the vehemence of Dr Benbow's criticism of the WHO reflected the sensitive nature of drug companies' relationship with patient groups. Tim Reid, European director of Health Action International, which campaigns for the rational and ethical use of drugs, said: “Patients groups are so close to the industry, that they might as well be taking their money straight out of the drug company advertising budgets.” Graham Dukes, a former head of the WHO's medicines programme for Europe, said: “We know that patient groups are heavily influenced by drug companies. In the case of attention deficit hyperactivity disorder, for example, we know that the industry effectively financed the whole campaign – and we're not absolutely sure the condition actually exists.”

Dr Reid added that there were now moves afoot in the European Union to sanction direct to consumer advertising in the form of private-public partnership promotional campaigns. For this reason the industry was keen for everything to be very transparent. “That's not to say we support such a move in Europe,” he said. “There may be some degree of transparency, but that doesn't mean it's necessarily a good source of information for consumers.”

Backtracking

A copy of Dr Benbow's email was forwarded to Dr. Saraceno, who sent a further email to Mary Baker on 20 June seeking to explain his previous email to her. “It is obvious that my reply to your initial message was misunderstood and misinterpreted,” he wrote.

“As I stated very clearly in my message to you, WHO cannot receive funds from the pharmaceutical industry, but can receive funds from a variety of other organizations including NGOs, such as EPDA, whenever there is no conflict of interests. My suggestion that GSK should give funds to EPDA might have been clumsily worded; my intention was to convey that EPDA can raise funds for its activities from a variety of sources (including the pharmaceutical industry) and use its funds for a variety of purposes (including giving donations to WHO). This is not the case for WHO.

“At any rate, any donation can only be accepted in accordance with WHO rules and regulations, and precisely this has been the case with all other NGOs whose contributions are extremely useful to the production of the publication ‘Neurological Disorders: Public Health Challenges'. Therefore, in order to avoid a perception of conflict of interests for WHO, I would prefer to decline any financial support for this publication, particularly since I have never asked your NGO to mobilize funds from pharmaceutical companies, and I now find myself in a situation that I have not solicited.”

When asked about this correspondence, Dr Saraceno told the BMJ: “I was not soliciting any funds. I was in the process of preparing a new report about neurological disease in poor countries, and I was looking for some funding to help with the report and I received an email from the patient group. And the way I reacted was rather stupid. After sending this very unfortunate email I sent another one saying that I had expressed myself in an ambiguous way. I'm strongly against receiving any money from the pharmaceutical industry that would pose a conflict of interest. I started here at the WHO 10 years ago at a time when the mental health division was much closer and more reliant on the pharmaceutical industry, and I've spent ten years trying to stop that.”

The BMJ also spoke to Mary Baker: “Dr Saraceno said he needed money for the report and I said I knew where I might be able to get it. I approached GSK, who we’ve always worked closely with in the past, and they have a clear understanding of transparency. They said they would be able to give us the money for the report. There is absolutely no doubt in my mind that Dr Saraceno knew the $10 000 was coming from GSK and that he was intending to take it and disguise its origins by getting the EPDA to accept it first before passing it on.

“This incident highlights the difficulty facing the WHO in balancing the best interests of patients with a shortfall in funding. Their current policy about not accepting money from pharmaceutical companies is prohibitive in this sense. There needs to be a broader debate about how the WHO, patient groups, and pharmaceutical companies can work together in partnership to produce the best results for patients. The WHO needs to ask itself some serious questions about how it will manage to fund projects in the future.”

This is not the first time that questions have been raised about the nature of the relation between the WHO's mental health division and the pharmaceutical industry. In their book, Medicines Out of Control? social campaigners Charles Medawar and Anita Hardon documented the controversial links between the WHO's mental health division, the World Psychiatric Association, and the drug industry.1 In the mid-1990s, at the suggestion of the World Psychiatric Association, the division produced a report that advocated long term use of potentially addictive benzodiazepine drugs.2 Benzodiazepine manufacturers purchased many copies of the report. And one firm made a $500 000 donation to WHO's mental health division.

Funding pressure

However, as Ralph Edwards, the director of the WHO's drug monitoring centre in Uppsala, Sweden, warns, it wasn't only the mental health division that was being pushed by financial necessity to get closer than was desirable to the drug industry. “These days it's so hard to find anyone completely free of the pharmaceutical industry. A couple of years ago we wanted to publish a safety report on Lapdap [chlorproguanil-dapsone], the combination malaria treatment. The WHO's tropical disease research group had developed the treatment jointly with Glaxo, but Glaxo weren't happy with what we wanted to publish.

“This was a bad situation and it was very, very difficult. We raised the issue with WHO because we thought that there had not been enough safety studies done. We managed to get the report published eventually, after a lot of lobbying and pressure – but it was delayed for more than a year,” said Dr Edwards.

“It's an example of how tortuous it is working with pharmaceutical industry money. GSK stated at the time of the dispute that it “totally disagrees with the assertion that there is concern about Lapdap” and maintains that it is “an effective and well-tolerated therapy for the treatment of malaria.” The company claimed that “A draft [of the WHO Lapdap report] which GSK was given sight of contained many inaccuracies.”

When the BMJ referred its concerns about the Saraceno correspondence to WHO, a spokesman [Q to A can you give his name?] replied: “It's astonishing that the BMJ thinks there's a story here. Dr Saraceno sent a second email saying that he had not meant to ask for the money. So I don't think there's anything to answer.”

Mortality reduction with influenza vaccine in patients with pneumonia outside "flu" season: pleiotropic benefits or residual confounding?

Am J Respir Crit Care Med. 12 June 2009 / 1 September 2008; 178(5):527-33.
doi: 10.1164/rccm.200802-282OC. Epub 2008 Jun 12. PMID: 18556629.

Abstract

Rationale: Observational studies suggest a 50% mortality reduction for older patients receiving influenza vaccination; some deem this magnitude of benefit implausible and invoke confounding by the "healthy user effect" as an alternate explanation.

Objectives: To evaluate unrecognized confounding by hypothesizing the presence of a 50% mortality reduction with vaccination for patients with pneumonia outside of influenza season.

Methods: Clinical, laboratory, and functional data were prospectively collected on 1,813 adults with community-acquired pneumonia admitted to six hospitals outside of influenza season in the Capital Health region (AB, Canada). Vaccination status was ascertained by interview and chart review. Outcome was in-hospital mortality. Influenza-vaccinated patients were matched to a nonvaccinated control using propensity scores, and then multivariable regression was used to determine the independent association between vaccination and mortality.

Measurements and main results: The cohort consisted of 352 vaccine recipients and 352 matched control subjects. Most (85%) patients were 65 years or older, 29% had severe pneumonia, and 12% died. Influenza vaccination was associated with a 51% mortality reduction (28 of 352 [8%] died vs. 53 of 352 [15%] control subjects; unadjusted odds ratio [OR], 0.49; 95% confidence interval [CI], 0.30-0.79; P = 0.004) outside influenza season. Adjustment for age, sex, and comorbidities did not alter these findings (adjusted OR, 0.45; 95% CI, 0.27-0.76). More complete adjustment for confounding (e.g., functional and socioeconomic status) markedly attenuated these benefits and their statistical significance (adjusted OR, 0.81; 95% CI, 0.35-1.85; P = 0.61).

Conclusions: The 51% reduction in mortality with vaccination initially observed in patients with pneumonia who did not have influenza was most likely a result of confounding. Previous observational studies may have overestimated mortality benefits of influenza vaccination.

Flu shot does not cut risk of death in elderly

Reuters, 30 August 2008, 12:47
https://www.reuters.com/article/us-flu-elderly-idUSHAR96014920080829

New York (Reuters Health) – While influenza vaccination does provide protection against catching the flu, it does not have a major impact on death in the elderly, contrary to what some studies have suggested, a new study suggests.

In prior studies, an impressive 50 percent reduction in death from any cause had been noted in elderly people who got a flu shot, but some researchers were skeptical of this degree of benefit, suggesting that it may have been the result of the "healthy user effect." The new study supports this line of thinking.

The study included more than 700 elderly people, half of whom had gotten a flu shot and half of whom had not. After controlling for a variety of factors that were largely not considered or simply not available in previous studies, the researchers concluded that any death benefit "if present at all, was very small and statistically non-significant and may simply be a healthy-user artifact that they were unable to identify."

"The healthy-user effect," study chief Dr. Sumit Majumdar of the University of Alberta in Edmonton, Canada explained in a statement, "is seen in what doctors often refer to as their 'good' patients – patients who are well-informed about their health, who exercise regularly, do not smoke or have quit, drink only in moderation, watch what they eat, come in regularly for health maintenance visits and disease screenings, take their medications exactly as prescribed - and quite religiously get vaccinated each year so as to stay healthy. Such attributes are almost impossible to capture in large scale studies using administrative databases."

"Over the last two decades in the United Sates, even while (flu) vaccination rates among the elderly have increased from 15 to 65 percent, there has been no commensurate decrease in hospital admissions or all-cause mortality," added co-investigator Dr. Dean T. Eurich, who is also with the University of Alberta.

"Further, only about 10 percent of winter-time deaths in the United States are attributable to influenza, thus to suggest that the vaccine can reduce 50 percent of deaths from all causes is implausible in our opinion," he added.

The study involved 352 patients given the vaccine and 352 matched control subjects. Overall, 85 percent of patients were over 64 years of age. Severe pneumonia was seen in 29 percent of patients and 12 percent of the patients died.

Flu vaccination was, in fact, associated with reduced mortality of about 50 percent (8 percent vs. 15 percent mortality in the vaccinated and unvaccinated groups, respectively), and this finding did not change after accounting for age, gender, or co-existing illnesses.

However, after adjusting for other potential confounders, including functional and socioeconomic status, the mortality reduction was weakened and no longer statistically significant.

"Previous studies were likely measuring a benefit not directly attributable to the vaccine itself, but something specific to the individuals who were vaccinated – a healthy-user benefit or frailty bias," Eurich concluded in a statement.

Flu shot does not reduce risk of Death, research shows

American Thoracic Society, ScienceDaily, 31 August 2008
https://www.sciencedaily.com/releases/2008/08/080829091323.htm

Summary:
The widely-held perception that the influenza vaccination reduces overall mortality risk in the elderly does not withstand careful scrutiny, according to researchers. The vaccine does confer protection against specific strains of influenza, but its overall benefit appears to have been exaggerated by a number of observational studies that found a very large reduction in all-cause mortality among elderly patients who had been vaccinated.

The study included more than 700 matched elderly subjects, half of whom had taken the vaccine and half of whom had not. After controlling for a wealth of variables that were largely not considered or simply not available in previous studies that reported the mortality benefit, the researchers concluded that any such benefit "if present at all, was very small and statistically non-significant and may simply be a healthy-user artifact that they were unable to identify."

"While such a reduction in all-cause mortality would have been impressive, these mortality benefits are likely implausible. Previous studies were likely measuring a benefit not directly attributable to the vaccine itself, but something specific to the individuals who were vaccinated – a healthy-user benefit or frailty bias," said Dean T. Eurich,Ph.D. clinical epidemiologist and assistant professor at the School of Public Health at the University of Alberta. "Over the last two decades in the United Sates, even while vaccination rates among the elderly have increased from 15 to 65 percent, there has been no commensurate decrease in hospital admissions or all-cause mortality. Further, only about 10 percent of winter-time deaths in the United States are attributable to influenza, thus to suggest that the vaccine can reduce 50 percent of deaths from all causes is implausible in our opinion."

Dr. Eurich and colleagues hypothesized that if the healthy-user effect was responsible for the mortality benefit associated with influenza vaccination seen in observational studies, there should also be a significant mortality benefit present during the "off-season".

To determine whether the observed mortality benefits were actually an effect of the flu vaccine, therefore, they analyzed clinical data from records of all six hospitals in the Capital Health region in Alberta. In total, they analyzed data from 704 patients 65 years of age and older who were admitted to the hospital for community-acquired pneumonia during non-flu season, half of whom had been vaccinated, and half of whom had not. Each vaccinated patient was matched to a non-vaccinated patient with similar demographics, medical conditions, functional status, smoking status and current prescription medications.

In examining in-hospital mortality, they found that 12 percent of the patients died overall, with a median length of stay of approximately eight days. While analysis with a model similar to that employed by past observational studies indeed showed that patients who were vaccinated were about half as likely to die as unvaccinated patients, a finding consistent with other studies, they found a striking difference after adjusting for detailed clinical information, such as the need for an advanced directive, pneumococcal immunizations, socioeconomic status, as well as sex, smoking,

functional status and severity of disease. Controlling for those variables reduced the relative risk of death to a statistically non-significant 19 percent.

Further analyses that included more than 3,400 patients from the same cohort did not significantly alter the relative risk. The researchers concluded that there was a difficult to capture healthy-user effect among vaccinated patients.

"The healthy-user effect is seen in what doctors often refer to as their 'good' patients – patients who are well-informed about their health, who exercise regularly, do not smoke or have quit, drink only in moderation, watch what they eat, come in regularly for health maintenance visits and disease screenings, take their medications exactly as prescribed – and quite religiously get vaccinated each year so as to stay healthy. Such attributes are almost impossible to capture in large scale studies using administrative databases," said principal investigator Sumit Majumdar, M.D., M.P.H., associate professor in the Faculty of Medicine & Dentistry at the University of Alberta.

The finding has broad implications:

- **For patients**: People with chronic diseases such as chronic respiratory diseases such as chronic obstructive pulmonary disease, immuno-compromised patients, healthcare workers, family members or friends who take care of elderly patients and others with greater exposure or susceptibility to the influenza virus should still be vaccinated. "But you also need to take care of yourself. Everyone can reduce their risk by taking simple precautions," says Dr. Majumdar. "Wash your hands, avoid sick kids and hospitals during flu season, consider antiviral agents for prophylaxis and tell your doctor as soon as you feel unwell because there is still a chance to decrease symptoms and prevent hospitalization if you get sick – because flu vaccine is not as effective as people have been thinking it is."
- **For vaccine developers**: Previously reported mortality reductions are clearly inflated and erroneous–this may have stifled efforts at developing newer and better vaccines especially for use in the elderly.
- **For policy makers**: Efforts directed at "improving quality of care" are better directed at where the evidence is, such as hand-washing, vaccinating children and vaccinating healthcare workers.

Finally, Dr. Majumder said, the findings are a reminder to researchers that "the healthy-user effect is everywhere you don't want it to be."

The results will appear in the first issue for September of the American Journal of Respiratory and Critical Care Medicine, a publication of the American Thoracic Society.

Influenza vaccine effectiveness among children 6 to 59 months of age during 2 influenza seasons: a case-cohort study.

Arch Pediatr Adolesc Med. October 2008, 162(10): 943-51.
doi: 10.1001/archpedi.162.10.943. PMID: 18838647

Abstract

Objective: To measure vaccine effectiveness (VE) in preventing influenza-related health care visits among children aged 6 to 59 months during 2 consecutive influenza seasons.

Design: Case-cohort study estimating effectiveness of inactivated influenza vaccine in preventing inpatient/outpatient visits (emergency department [ED] and outpatient clinic). We compared vaccination status of laboratory-confirmed influenza cases with a cluster sample of children from a random sample of practices in 3 counties (subcohort) during the 2003-2004 and 2004-2005 seasons.

Setting: Counties encompassing Rochester, New York, Nashville, Tennessee, and Cincinnati, Ohio.

Participants: Children aged 6 to 59 months seen in inpatient/ED or outpatient clinic settings for acute respiratory illnesses and community-based subcohort comparison. Main Exposure Influenza vaccination.

Main outcome measures: Influenza vaccination status of cases vs subcohort using time-dependent Cox proportional hazards models to estimate VE in preventing inpatient/ED and outpatient visits.

Results: During the 2003-2004 and 2004-2005 seasons, 165 and 80 inpatient/ED and 74 and 95 outpatient influenza cases were enrolled, while more than 4500 inpatient/ED and more than 600 outpatient subcohorts were evaluated, respectively. In bivariate analyses, cases had lower vaccination rates than subcohorts. However, significant influenza VE could not be demonstrated for any season, age, or setting after adjusting for county, sex, insurance, chronic conditions recommended for influenza vaccination, and timing of influenza vaccination (VE estimates ranged from 7%-52% across settings and seasons for fully vaccinated 6- to 59-month-olds).

Conclusion: In 2 seasons with suboptimal antigenic match between vaccines and circulating strains, we *could not demonstrate* VE in *preventing influenza-related inpatient*/ED or outpatient visits in children younger than 5 years. Further study is needed during years with good vaccine match.

Boston launches flu shot tracking
City to pinpoint areas of low rates of vaccination

Boston.com, 21 November 2008
https://web.archive.org/web/20090803091728/http://www.boston.com/news/local/massachusetts/articles/2008/11/21/boston_launches_flu_shot_tracking/
https://web.archive.org/web/20090804090328/http://www.boston.com/news/local/massachusetts/articles/2008/11/21/boston_launches_flu_shot_tracking?page=2

Using technology originally developed for mass disasters, Boston disease trackers are embarking on a novel experiment - one of the first in the country - aimed at eventually creating a citywide registry of everyone who has had a flu vaccination.

The resulting vaccination map would allow swift intervention in neighborhoods left vulnerable to the fast-moving respiratory illness.

The trial starts this afternoon, when several hundred people are expected to queue up for immunizations at the headquarters of the Boston Public Health Commission. Each of them will get a bracelet printed with a unique identifier code. Information about the vaccine's recipients, and the shot, will be entered into handheld devices similar to those used by delivery truck drivers.

Infectious disease specialists in Boston and elsewhere predicted that the registry approach could prove even more useful if something more sinister strikes: a bioterrorism attack or the long-feared arrival of a global flu epidemic. In such crises, the registry could be used to track who received a special vaccine or antidote to a deadly germ.

"Anything you can do to better pinpoint who's vaccinated and who's not, that's absolutely vital," said Michael Osterholm, director of the Center for Infectious Disease Research & Policy at the University of Minnesota. "I wish more cities were doing this kind of thing."

Boston is believed to be the first city to embrace this particular approach to tracking vaccinations against the seasonal flu, estimated to kill 36,000 people each year in the United States, principally the elderly.

But when Boston bought the monitoring system from a Milwaukee company in 2006, emergency authorities had a far different use in mind: tracking people injured in big fires, plane crashes, or other disasters.

"When there's a large catastrophic event, people end up in a variety of healthcare facilities," said Dr. Anita Barry, Boston's director of communicable disease control. "Of course, their family members and loved ones are trying to find out where they are and how they're doing."

To see how well the system would work, emergency crews tested it at the Boston Marathon and the Fourth of July extravaganza on the Esplanade. The trial proved successful.

"If we can make it work in the Boston Marathon medical tent, then you have to think about making it so that it can work in other environments as well - whether it's a community clinic or a doctor's office or a flu shot clinic," said Rich Serino, chief of Boston Emergency Medical Services. Thus, the idea to use the registry as a flu vaccine tracker was born.

Every autumn in medical offices across the country, flu vaccine floods in. The perishable medical product must be delivered to millions in a matter of months.

Keeping track of that cache of vaccine - and which patients are getting it - is a daunting proposition.

In some medical offices, the information is entered into electronic medical records. At Boston's health department, nurses fill out paper forms.

But there's never been any way to systematically monitor whether, for example, Dorchester has lower vaccination rates than the North End.

"When you're working in one clinic, you don't have a good sense of that," said Dr. Alfred DeMaria, top disease doctor at the Massachusetts Department of Public Health. "But if you're tracking multiple clinics in real time, you can see where the uptake is better and where it's less, and then focus on outreach."

Today's experiment, which does not require any additional direct spending, is a first step toward that.

When people arrive for their shots, they will get an ID bracelet with a barcode. Next, basic information - name, age, gender, address - will be entered into the patient tracking database. There will be electronic records, too, of who gave the vaccine and whether it was injected into the right arm or the left, and time-stamped for that day.

The resulting trove of data could be used to figure out why some patients had to wait longer than others to be vaccinated. "When all is said and done," said Jun Davantes, director of product management at EMSystems, the company that makes the technology, "Boston will be able to identify where there are certain bottlenecks in the process and hopefully improve it the next time around."

Ultimately, city health authorities said, they envision creating a network across the city that would allow public and private providers of flu shots to add data to a registry.

But acknowledging patients' privacy concerns, officials promised that if a citywide system were implemented, only a limited amount of information would be gathered - all sitting behind an encrypted firewall.

"I have had people say, 'Oh, that's so big brother,' " said Laura Williams, EMS deputy chief of staff. "But in truth, the unique identifier is unique to the incident. It's not like you will go to the hospital, and they'll say, 'You're the one who got the flu vaccine at 10 o'clock yesterday at the Boston Public Health Commission.' "

The New York Times

Lessons From the Non-Pandemic of 1976

The New York Times, 30 April 2009, 1:29
https://archive.nytimes.com/thelede.blogs.nytimes.com/2009/04/30/lessons-from-the-non-pandemic-of-1976/

CDC Public Health Image Library During a national immunization campaign in 1976, millions of Americans were given shots of a vaccine against a strain of swine flu.

As news and concern about the swine flu spreads around the world, governments and public health officials are walking a fine line: They try to alert people to the dangers of the illness without stoking people's fears. As a post on our politics and government blog, The Caucus, noted this morning, remarks by Vice President Joe Biden illustrated that politicians are often not very good at walking such fine lines.

As if to prove that Democrats have no lock on spreading confusion about the swine flu, or on cases of foot-in-mouth disease, here is a short burst of Rep. Michele Bachmann, Republican of Minnesota, who said, incorrectly, during a recent interview on the conservative Web site Pajamas TV that the outbreak of swine flu in 1976, which killed one person at Fort Dix, N.J., took place "under another Democrat [sic] President, Jimmy Carter — and I'm not blaming this on President Obama, I just think it's an interesting coincidence."

While Mr. Carter was of course elected in 1976, Ms. Bachmann seemed not to know just when the swine flu outbreak took place, or to remember that President Gerald Ford, a Republican, was still in office every day of that year, when the government developed a vaccine and tried to immunize every American to head off a pandemic:

So what did happen in 1976, and what lessons might we now take from that effort to prevent a swine flu outbreak from spreading worldwide?

The main thing that many people who are following the current swine flu outbreak on the Web seem to know about 1976 is that the government produced two public-service announcements meant to scare people into getting the vaccine, and that they now look equal parts ominous and funny:

As experts now consider whether to produce a vaccine against this new strain of swine flu, it is worth looking back at the controversy that surrounded the mass immunization campaign in 1976.

In an article about flu pandemics and non-pandemics for The New York Times Magazine in 1992, Robin Marantz Henig recalled:

Influenza experts thought they saw big-league trouble coming in February 1976, when a few cases of severe swine flu broke out among young military recruits in Fort Dix, N.J. One of them, Pvt. David Lewis, 19, died. Of 19 patients whose specimens were sent to the Centers for Disease Control for virus typing, Lewis and four others were shown to be infected with the same H1N1 influenza virus as was responsible for the 1918 pandemic. This got many public-health officials into gear, hoping to use modern technology, namely vaccination, to head off a disaster of the magnitude of 1918.

The large-scale effort to manufacture and distribute enough vaccine for everyone in the country showed that millions of doses of high-quality vaccine could be made in a matter of three or four months. But the swine-flu pandemic never materialized. In retrospect, some critics now say 40 million Americans were vaccinated for nothing.

As Andrew Pollack reported in The New York Times a few years ago, the Ford administration's aggressive approach in 1976 may have wound up doing more harm than good:

That is the year President Gerald R. Ford announced a crash program to "inoculate every man, woman and child in the United States" against swine flu. But the virus never became a killer, and vaccinations were halted two months after they began after reports that 500 people who received the shot developed a paralyzing nerve disease and more than 30 of them died.

In an article in The Los Angeles Times last Saturday, "Swine flu 'debacle' of 1976 is recalled," Shari Roan explained that "the federal government paid millions in damages to people or their families" who contracted the nerve disease, Guillain-Barre syndrome, after getting the vaccine that year.

Still, some influenza experts defended the aggressive approach of 1976. For her 1992 article, Ms. Henig talked to Dr. Edwin D. Kilbourne, "an early and consistent advocate of mass immunization in 1976," who had the vaccine virus produced in his lab at Mount Sinai Medical School in New York City. Dr. Kilbourne argued that the government had acted rationally at the time, since the aim was to avoid death on the scale of the 1918 pandemic. "Better a vaccine without an epidemic," Dr. Kilbourne said, "than an epidemic without a vaccine."

Dr. Richard P. Wenzel, the chairman of internal medicine at Virginia Commonwealth University, who also advocated vaccination in 1976, still says "it was a great effort." Dr. Wenzel told The Los Angeles Times on Saturday that while the immunization program "had unexpected, unfortunate side effects," he hoped that "there will be a lot of good, honest public health discussion about what happened in 1976."

As Dr. Pascal J. Imperato, dean of the school of public health at the State University of New York Downstate Medical Center, who was the chairman of the New York City Swine Flu Task Force in 1976, told Donald McNeil of The New York Times on Wednesday that the new strain that emerged that year was identified quickly enough to make containment a viable strategy. All 230 infected soldiers at Fort Dix, N.J., were kept on the base, Dr. Imperato said. "They had no external contacts. One died, the rest had mild infection."

With reports from Peru and Switzerland on Thursday, there are now at least 13 countries that have confirmed cases of the new strain of H1N1 swine flu. But as Ms. Henig wrote in 1992, one of the lessons that experts like Dr. Kilbourne took from the experience of 1976 was that some new strains of flu may not be virulent enough to merit mass immunization, but that it was still a good idea to get vaccine ready, just in case:

In hindsight, those involved in the decision-making realize that major variants of influenza virus in a few individuals do not necessarily signal the start of a new pandemic. Some variants prove easily transmitted; most, like the Fort Dix strain, will die out after a few passages through human hosts. "Early detection of a new virus therefore may not be adequate evidence on which to undertake mass immunization," Kilbourne wrote in a 1979 article called "Swine Flu: The Virus That Vanished." "But it is, I believe, a signal at least to produce vaccine to hold in readiness."

Last Saturday, the Science magazine blog Science Insider interviewed Dr. Kilbourne, now 88 and retired, and asked him how he thought the lessons of 1976 might be applied to today's crisis. Dr. Kilbourne defended the immunization campaign, arguing that the cases of Guillain-Barré syndrome may not have been caused by the vaccine, and said that a vaccine should be made as soon as possible this year, even if it will then be held in reserve until the new strain is known to be virulent:

The only thing I would have done differently in 1976, retrospectively, is to make the vaccine, promote the vaccine, but not give the vaccine until the last moment — but the problem with that is that you may be too late. By all means, find the prevalent strain, make a vaccine that can be used, and grow it in eggs, and then go with it. [But] I think it's premature to do it [vaccinate] now.

Death of volunteers during clinical trials

dziennik.pl

Szczepionkę na ptasią grypę testowali na bezdomnych

Dziennik.pl, 2 lipca 2008, (2 July 2008) 03:09
https://wiadomosci.dziennik.pl/wydarzenia/artykuly/126671,szczepionke-na-ptasia-grype-testowali-na-bezdomnych.html

Za każde zaszczepienie nowym specyfikiem przeciwko grypie bezdomni z Grudziądza dostawali od przychodni po 5-10 złotych. Nie wiedzieli jednak, że nie chodziło o zwykłą grypę, a o siejącą na świecie spustoszenie ptasią grypę. Kilkanaście osób zmarło. Czy ich śmierć miała związek z testami? Do szokujących informacji dotarł reporter "Faktów" TVN. Zachowanie lekarzy potępiła minister zdrowia Ewa Kopacz.

Bezdomni twierdzą, że nie wiedzieli, iż szczepią ich przeciwko ptasiej grypie. W kwietniu 2007 roku grudziądzka przychodnia "Dobra Praktyka" wysłała do nich zapytanie, w którym była mowa o nieodpłatnym przekazaniu szczepionki przeciw zwykłej grypie o nazwie VAXIGRIP. Za każdą szczepionkę mieli dostać pieniądze, dlatego niektórzy zaszczepili się nawet kilkanaście razy. Dopiero teraz okazało się, że otrzymali dwie dawki szczepionki FLUAD- H5N1, która była ocenianą w tym badaniu szczepionką przeciwko groźnemu wirusowi grypy H5N1.

Tuż po szczepieniach kilkanaście osób zmarło. Nie wiadomo, czy testowanie szczepionki było przyczyną śmierci bezdomnych. Wielu z nich to osoby schorowane i wycieńczone trybem życia, dla których takie eksperymenty mogą być niebezpieczne. Statystyka daje jednak wiele do myślenia.

"W 2004 roku zmarło czterech bezdomnych z naszego ośrodka" - przyznaje w rozmowie z "Faktami" Mieczysław Wacławski, kierownik schroniska im św. Brata Alberta w Grudziądzu. Jednak w 2005 i 2006 roku zmarło łącznie 16 osób, w 2007 roku - roku, w którym testowano szczepionkę - aż 21. Według TVN24, pokrzywdzonych może być nawet 350 osób. Około 150 z nich - to bezdomni. Reszta to zwyczajni mieszkańcy, zwabieni zarobkiem.

Kierownictwo przychodni broni się, że wszyscy pacjenci podpisali zgodę na szczepienie i wiedzieli, przeciwko czemu się szczepią.

Wczoraj do toruńskiego sądu wpłynął akt oskarżenia przeciwko trojgu lekarzom i sześciu pielęgniarkom. Jak wykazało śledztwo, oszukali oni nie tylko pacjentów, ale i firmę farmaceutyczną, która zleciła szczepienia. Prokuratura zarzuca im fałszowanie dokumentacji, nakłanianie świadków do składania fałszywych zeznań i poświadczanie nieprawdy, a także przywłaszczenia mienia. Zarzut narażenia zdrowia i życia bezdomnych jednak w akcie oskarżenia nie pada.

Zachowaniem lekarzy oburzona jest minister zdrowia. "Lekarze, którzy prowadzili te badania, nie powinni wracać do zawodu" – tak oskarżonych lekarzy oceniła w programie "Fakty po Faktach" Ewa Kopacz. "W interesie wszystkich lekarzy leży, by ci, którzy zawinili, ponieśli karę" - dodała.

Homeless people die after bird flu vaccine trial in Poland

Three Polish doctors and six nurses are facing criminal prosecution after a number of homeless people died following medical trials for a vaccine to the H5N1 bird-flu virus.

The Telegraph, UK, 2 July 2008, 4:37 pm

https://www.telegraph.co.uk/news/worldnews/europe/poland/2235676/Homeless-people-die-after-bird-flu-vaccine-trial-in-Poland.html
https://web.archive.org/web/20080706125740/https://www.telegraph.co.uk/news/worldnews/europe/poland/2235676/Homeless-people-die-after-bird-flu-vaccine-trial-in-Poland.html

The medical staff, from the northern town of Grudziadz, are being investigated over medical trials on as many as 350 homeless and poor people last year, which prosecutors say involved an untried vaccine to the highly-contagious virus.

Authorities claim that the alleged victims received £1-2 to be tested with what they thought was a conventional flu vaccine but, according to investigators, was actually an anti bird-flu drug.

The director of a Grudziadz homeless centre, Mieczyslaw Waclawski, told a Polish newspaper that last year, 21 people from his centre died, a figure well above the average of about eight.

Although authorities have yet to prove a direct link between the deaths and the activities of the medical staff, Poland's health minister, Ewa Kopacz, has said that the doctors and nurses involved should not return to their profession.

"It is in the interests of all doctors that those who are responsible for this are punished," the minister added.

Investigators are also probing the possibility that the medical staff may have also have deceived the pharmaceutical companies that commissioned the trials.

The suspects said that the all those involved knew that the trial involved an anti-H5N1 drug and willingly participated.

The news of the investigation will come as another blow to the reputation of Poland's beleaguered and poverty-stricken national health service. In 2002, a number of ambulance medics were found guilty of killing their patients for commissions from funeral companies.

MED НОВОСТИ

В Польше несколько бездомных умерли во время испытаний вакцины от птичьего гриппа

MED media, 3 июля 2008, 18:19
https://medportal.ru/mednovosti/v-polshe-neskolko-bezdomnyh-umerli-vo-vremya-ispytaniy-vaktsiny-ot-ptichiego-grippa/

В Польше возбуждено уголовное дело в отношении трех врачей и шести медсестер, предположительно привлекавших постояльцев приюта для бездомных к клиническим испытаниям вакцины против птичьего гриппа. По данным администрации, за время исследования смертность в приюте выросла почти в три раза.

Согласно сообщениям местных СМИ, незаконные испытания экспериментального препарата проводились в приюте польского города Грудзёндз в 2007 году. За каждую прививку испытуемые получали вознаграждение в размере 5-10 злотых, причем некоторые из них прививались по десять и более раз. Как предполагают следователи, испытуемым сообщали, что на них тестируют утвержденный препарат от обычного гриппа, на самом же деле им вводили экспериментальную вакцину для защиты от вируса птичьего гриппа H5N1.

Следователи считают также, что организаторы эксперимента вводили в заблуждение разработчиков препарата, которые ничего не знали о методах подбора и составе участников исследования.

По данным директора приюта Мечислава Вацлавского, в течение 2007 года скончался 21 постоялец этого социального учреждения, тогда как предыдущие годы там фиксировалось в среднем не более 9 смертей в год.

Хотя причинно-следственная связь между всплеском смертности и незаконными испытаниями пока не доказана, министр здравоохранения Польши Эва Копач уже заявила о решимости строжайшим образом покарать виновных.

В свою очередь, подозреваемые в грубых нарушениях медицинской этики медики продолжают настаивать на своей невиновности. По их словам, все привлеченные к испытаниям люди были предупреждены о возможных рисках и подписали информированное согласие на участие в исследовании.

BanderasNEWS.COM

12 Babies Die During Vaccine Trials in Argentina

Trading Markets // Banderas News, 8 July 2009
https://www.banderasnews.com/0807/hb-vaccinetrials.htm

Buenos Aires - At least 12 babies who were part of a clinical study to test the effectiveness of a vaccine against pneumonia have died over the past year in Argentina, the local press reported Thursday.

The study was sponsored by global drug giant GlaxoSmithKline and uses children from poor families, who are "pressured and forced into signing consent forms," the Argentine Federation of Health Professionals, or Fesprosa, said.

"This occurs without any type of state control" and "does not comply with minimum ethical requirements," Fesprosa said.

The vaccine trial is still ongoing despite the denunciations, and those in charge of the study were cited by the Critica newspaper as saying that the procedures are being carried out in a lawful manner.

Colombian and Panama were also chosen by GSK as staging grounds for trials of the vaccine against the pneumococcal bacteria.

Since 2007, 15,000 children under the age of one from the Argentine provinces of Mendoza, San Juan and Santiago del Estero have been included in the research protocol, a statement of what the study is trying to achieve.

"Only 12 have died throughout the country, which is a very low figure if we compare it with the deaths produced by respiratory illnesses caused by the pneumococcal bacteria," pediatrician Enrique Smith, one of the lead investigators, said.

In Santiago del Estero, one of the country's poorest provinces, the trials were authorized when Enrique's brother, Juan Carlos Smith, was provincial health minister.

According to pediatrician Ana Maria Marchese, who works at the children's hospital in the provincial capital where the studies are being conducted, "because they can't experiment in Europe or the United States, they come to do it in third-world countries."

"A lot of people want to leave the protocol but aren't allowed; they force them to continue under the threat that if they leave they won't receive any other vaccine," said Julieta Ovejero, great aunt of one of the six babies who died in Santiago del Estero.

Fesprosa's Juan Carlos Palomares said that "in most cases these are underprivileged individuals, many of them unable to read or write, who are pressured into including their children" in the trials.

According to Fesprosa, "the laboratory pays $8,000 for each child included in the study, but none (of that money) remains in the province that lends the public facilities and the health personnel for the private research."

Is GlaxoSmithKline Behaving Badly in Argentina?

Santiago del Estero / ABC News, 23 September 2008
https://www.corpwatch.org/article/argentina-glaxosmithkline-behaving-badly-argentina

Parents Allege Pharmaceutical Giant Tricked Them with Experimental Vaccine.

Maria Ester, 23, lives in a crumbling, one-room stucco cottage with her mother and daughter in Santiago del Estero, an Argentine province northwest of Buenos Aires.

Ester's 5-year-old daughter and assorted neighborhood children crowd the room, and a sagging mattress that smells like it belongs to a young bed wetter is the only place for a visitor to sit down.

An adult might find the room oppressive. But from a child's perspective, a benefit to living in a shanty is that no one really minds if you draw on the walls. Ester's walls are colorfully scribbled.

Sharp-featured, with glossy hair and warm, brown skin, Ester's small body is still plump with baby weight. She had another daughter, Michaela, but the 5-month-old died May 28.

Michaela had been one of more than 13,000 Argentine children to participate in a clinical study implemented a little more than a year ago by the London-based GlaxoSmithKline, the world's second-largest drug manufacturer.

Streptococcus pneumoniae is a major cause of meningitis and pneumonia in children in Latin America. More than 12 million pneumonia episodes occur each year in this region in children under five and it is estimated that at least 50,000 children die each year of pneumonia in the region according to 2006 data from UNICEF.

Ester says that if her infant hadn't participated in the study Michaela would still be alive.

Protocol Compas is the name of the study designed to test the efficacy of Synflorix, GSK's experimental pediatric pneumonia vaccine, which can also ward off the bacteria that causes meningitis and ear infections. Synflorix is still in the preapproval stage.

GSK compares Synflorix with Wyeth's hugely successful Prevnar vaccine, which has proved effective in the United States. Besides Argentina, trials are also being conducted in Panama, Chile and Colombia.

The Outsourcing of Clinical Studies

Americans are swallowing more prescription medications than ever, and the ever-increasing appetite for pharmaceuticals has fueled the drug industry's search for cheaper and faster ways to conduct clinical testing.

In 1997, the United States conducted 5 percent of its clinical studies outside of the United States and Western Europe, according to a study conducted by Tufts Center for Drug Development. By 2007, that number had climbed to 29 percent.

Because of the multinational business of major drug companies, and how Americans fit in as U.S.-based employees and stockholders of GSK, as well as consumers of drugs that will be available in the U.S. market, there are global ramifications of clinical testing being conducted around the world.

The lion's share of drug studies has gone to regions with "emerging markets": Eastern Europe and Central Europe, Latin America, and south and Southeast Asia. In order for a region to be of use to a legitimate drug company, the country has to maintain a minimal level of infrastructure, says Mary Jo Lamberti, director of market research at the Boston-based Center Watch, a consulting firm that bills itself as the "Global Destination for Clinical Trials Information."

According to Fortune magazine, it takes about $900 million to bring a new drug to market, and procuring and retaining human subjects typically accounts for about 40 percent of a drug company's budget. Conducting trials in regions considered "poor" by Western standards makes economic sense.

Yet money is not the only factor in the equation, Lamberti says, whose work includes helping pharmaceutical companies find suitable locations for clinical trials. It's easier and takes far less time to find suitable subjects in many developing countries, she says, because they have large "drug naive" populations.

In other words, a large percentage of Americans are already on various medications, so it's difficult to find subjects with unadulterated -- that is, completely unmedicated -- bodies in the United States.

Critics say there is an additional issue that has yet to be taken seriously.

Individual countries generally have their own boards of medical professionals charged with setting standards to ensure the safety of their citizens. And the United States, for example, has an arm of the Food and Drug Administration tasked with overseeing clinical studies performed abroad. The trouble, critics say, is that the standards that exist are sometimes not upheld.

Sonia Shah, author of the 2006 book "The Body Hunters: Testing Drugs on the World's Poorest Patients," tells ABCNews.com that there is a "whole steamrolling industry that needs more and more subjects."

She adds, "[The] political will is not there" to protect the interests of those who put their bodies at risk.

Clinical Study: 'Adverse Events Can Arise'

Pneumococcal diseases – that is, diseases caused by bacteria that cause pneumonia, middle ear infections, meningitis and blood infections – are a serious problem in Latin America. According to international health organizations, each year more than 50,000 children die from them.

Dr. Ricardo Ruttiman, the regional medical affairs and research and development director of GlaxoSmithKline responsible for Protocol Compas in Argentina, says the study is being conducted in three Argentine provinces -- Santiago, Mendoza and San Juan. Ruttiman says Compas clinical studies began a little more than a year ago.

Twelve Argentine children who participated in Protocol Compas have died, and of those 12, seven are being mourned in Santiago del Estero, one of Argentina's poorest provinces. Like Ester, many of the parents reportedly blame what they know as Protocol Compas, or simply, Compas.

"Within the COMPAS trial an Independent Data Monitoring Committee (IDMC) oversees safety aspects of the study and ensure that the highest ethical and compliance standards are followed," said Sarah Alspach, director of US Media Relations for GlaxoSmithKline. "The mortality rate of children participating in the COMPAS study is closely monitored by the IDMC and does not exceed the rate in the regions and countries participating in the study."

Some parents say they didn't know that their children were participating in a study at all. Others claim to have been coerced into participating – a suggestion rebutted by Ruttiman, who told ABCNews.com that participation is always voluntary and that parents "are informed, clearly and in a language they can understand, by experienced medical investigators."

They are informed not only about the benefits, he says, such as round-the-clock access to medical care and vaccinations against diseases such as diphtheria, tetanus and hepatitis, but about potential risks.

Ruttiman says there are few risks. The safety of the drug has already been proved, he says, and the vaccine's efficacy against respiratory infections is only being tested.

He adds that "the vaccines used in this study may cause adverse reactions unknown up to now. & As with any vaccine, unexpected adverse events can arise, including allergic reactions."

Ester, who earns a living cleaning houses, says Michaela is among those who experienced an "adverse event."

Three weeks before Christmas, a nurse's aide came to the Esters' home. The nurse's aide, says Ester, who spoke to ABCNews.com through a translator, told her that doctors at the Eva Peron Children's Hospital, Santiago Del Estero's primary children's hospital, wanted to give Michaela a vaccine.

Ester - who told her story to ABCNews.com and a small audience that included five neighborhood children sitting as quietly as possible on the pungent bed -- says that a friend had warned her to stay away from Protocol Compas. The friend told Ester that she knew of another new mother whose baby reportedly suffered health problems after participating in the study, according to Ester.

Ester only gave in, she says, when the nurse's aide threatened to go to the police and have her baby taken away from her. "I didn't know if the doctors, the police, the system would take her away, but I was afraid," she added.

Ester soon signed a 12-page consent form she says she couldn't really understand. Then she allowed Michaela to receive her first injection.

Many health-care professionals assert that holding clinical trials in regions with poor health-care systems has the potential to benefit everyone. GSK's Ruttiman points out that because of the high quality of care the children in the study receive, the infant mortality rate is significantly lower in those who participate in Protocol Compas than in those who do not. Ruttiman would not comment on individual cases citing patient privacy.

Benjamin Wilfond, head of Seattle's Treuman Katz Center for Pediatric Bioethics, says that although he is unfamiliar with Protocol Compas, it's difficult to know what really happened between Ester and the nurse's aide.

"I have no doubt that that was how [Ester] experienced the process. And you will not find anyone who will defend coercion," he said. "But I was in Argentina a few years ago, and the internal regulations seemed quite robust. It could very well be true, because even if the process is being appropriately reviewed, it's difficult to monitor what goes on [on] the ground, what individuals take it upon themselves to do. But I would be wary [of such accounts]. The death of a child could be processed in all sorts of ways. It could very well be true. But I am skeptical."

Trading participation in a medical trial for health care has become the standard operating procedure for drug companies and/or their medical contractors, according to Shah. Some see it as win-win, but Shah views the trade as nearly as coercive as the dramatic threat Ester alleges she received.

"The argument I make is that the drug companies are going [abroad] because people have less access to health care," said Shah. "So they offer incentives and the choice is, 'participate in the trial or your children won't get health care.' That's not a choice. Being in an experiment is not the same as standard care. In an experiment [the drug] might work, you might get a placebo or it might be worse than nothing. They might suffer some terrible unforeseen consequence."

Tricked Into Participation?

When it comes to Protocol Compas specifically, Dr. Ana Maria Marchesse of Eva Peron Children's Hospital is one of several Argentine doctors who is highly critical of the study's methodology.

She heads up the Health Professionals' Labor Association, a group of local doctors who alerted La Federacion de Profesionals de la Salud de la Republica Argentina (the Argentinean FDA) of their concerns about possible wrongdoing.

"It's impossible to say whether the 12 babies' deaths are due to the vaccine or not, because half of the [total number of] children were given a placebo," the pediatrician told ABCNews.com through a translator. "But the way the study has been conducted is reprehensible."

A large part of the problem lies in the consent form, says Marchese. The language in the 12-page document is so convoluted, she charges, that even she had to read it more than once to fully grasp its meaning. Another problem is how subjects say they were recruited, Marchese says.

Claudia Nazarena Hoyos, 31, and Alvaro Martin Ovejero, 32, spoke to ABCNews.com in Ovejero's father's kitchen.

Hoyos and Ovejero allege that a Protocol Compas nurse's aide told them that 4-month-old Gabriel, who suffered from bronchial trouble, would probably get better if they allowed him to be a part of the study. Instead, Gabriel died two months after receiving his first injection.

Ovejero, who works as a part-time disc jockey, alleges the couple was misled by the "agente saniterio," a kind of nurse's aide, who told them about the study. "She did not say it was a test. She said it was a vaccine for his lungs that would keep him from getting worse."

One week after the baby received his first injection, says Hoyos, her son began to produce a lot of mucus. His eyes were perpetually runny, and his breathing grew slow and labored.

GlaxoSmithKline denies allegations of ethical misconduct. Ruttiman says the deaths have been analyzed, and says all of them were clearly unrelated to the vaccine. One child died in a choking incident, he says.

"GSK is saddened to hear of any mortality in clinical trials. Safety of patients is always our primary concern in the development of any new treatment or vaccine," Alspach said. "It is, however, important to review such cases in the context of the rates of post-neonatal infant mortality for the country in which the trial is being conducted."

Nevertheless, Ovejero insists that "something in the process was bad," and that his family and the other affected families "want to find out who or what is responsible."

Unintended Consequences

Global health advocates say bad press is making it difficult for doctors working with children in the developing world, even when the doctors have no connection to clinical studies.

The Nigerian state of Kano is one well-publicized example. In 2004, Kano's government refused to take part in the Global Polio Eradication Initiative sponsored by the World Health Organization out of fears that the immunizations constituted a plot to reduce the country's Muslim population.

According to The Associated Press, the boycott was initiated after Pfizer faced accusations made by families and human rights groups of putting about 200 children at risk during what they claimed was a poorly managed meningitis study 11 years ago.

Eleven children died, while others suffered brain damage, according to the Nigerian government, which this summer filed suit against the London- and Connecticut-based pharmaceutical company. The case is still pending.

Although the immunization boycott lasted 10 months, international health experts reportedly noted a rapid polio expansion, in a pattern that radiated from the west African state.

Shah says that the Kano example points to the public health issues at stake when countries lose trust in the pharmaceutical industry. "It's not that drug companies are trying to go out and harm people," she said. "They really hope and believe that their drugs will work."

Back in Argentina

Franklin Moyano, Santiago del Estero's health minister, told state news media that the province is conducting an independent investigation into the children's deaths. But the families of the children are taking matters into their own hands.

Ovejero, who wears a T-shirt bearing his late-son's photo, says that the family is planning to take legal action. The family also told Inter Press Service that their lawyer had been offered money to halt any legal action, but they rejected the offer.

A GlaxoSmithKline representative told ABCNews.com that the company was aware of reports in the Argentine press that Ovejero and his wife were offered money through their lawyer, but GSK said in an e-mail response, "The company has acknowledged this information through the articles that have been published in the media. Therefore, we do not have acquaintance of this fact."

In the meantime, Ovejero participates in weekly protest marches on the Plaza Liberdad, the town square. For the last month, every Monday around 7 p.m., close to 20 to 50 parents, extended family members and friends carry signs bearing the blown-up likenesses of their dead babies.

"Gabriel was born with a purpose," said Hoyos, Gabriel's mother. "His purpose was to bring justice."

POULTRY WORLD

Poland: bird flu vaccine scam

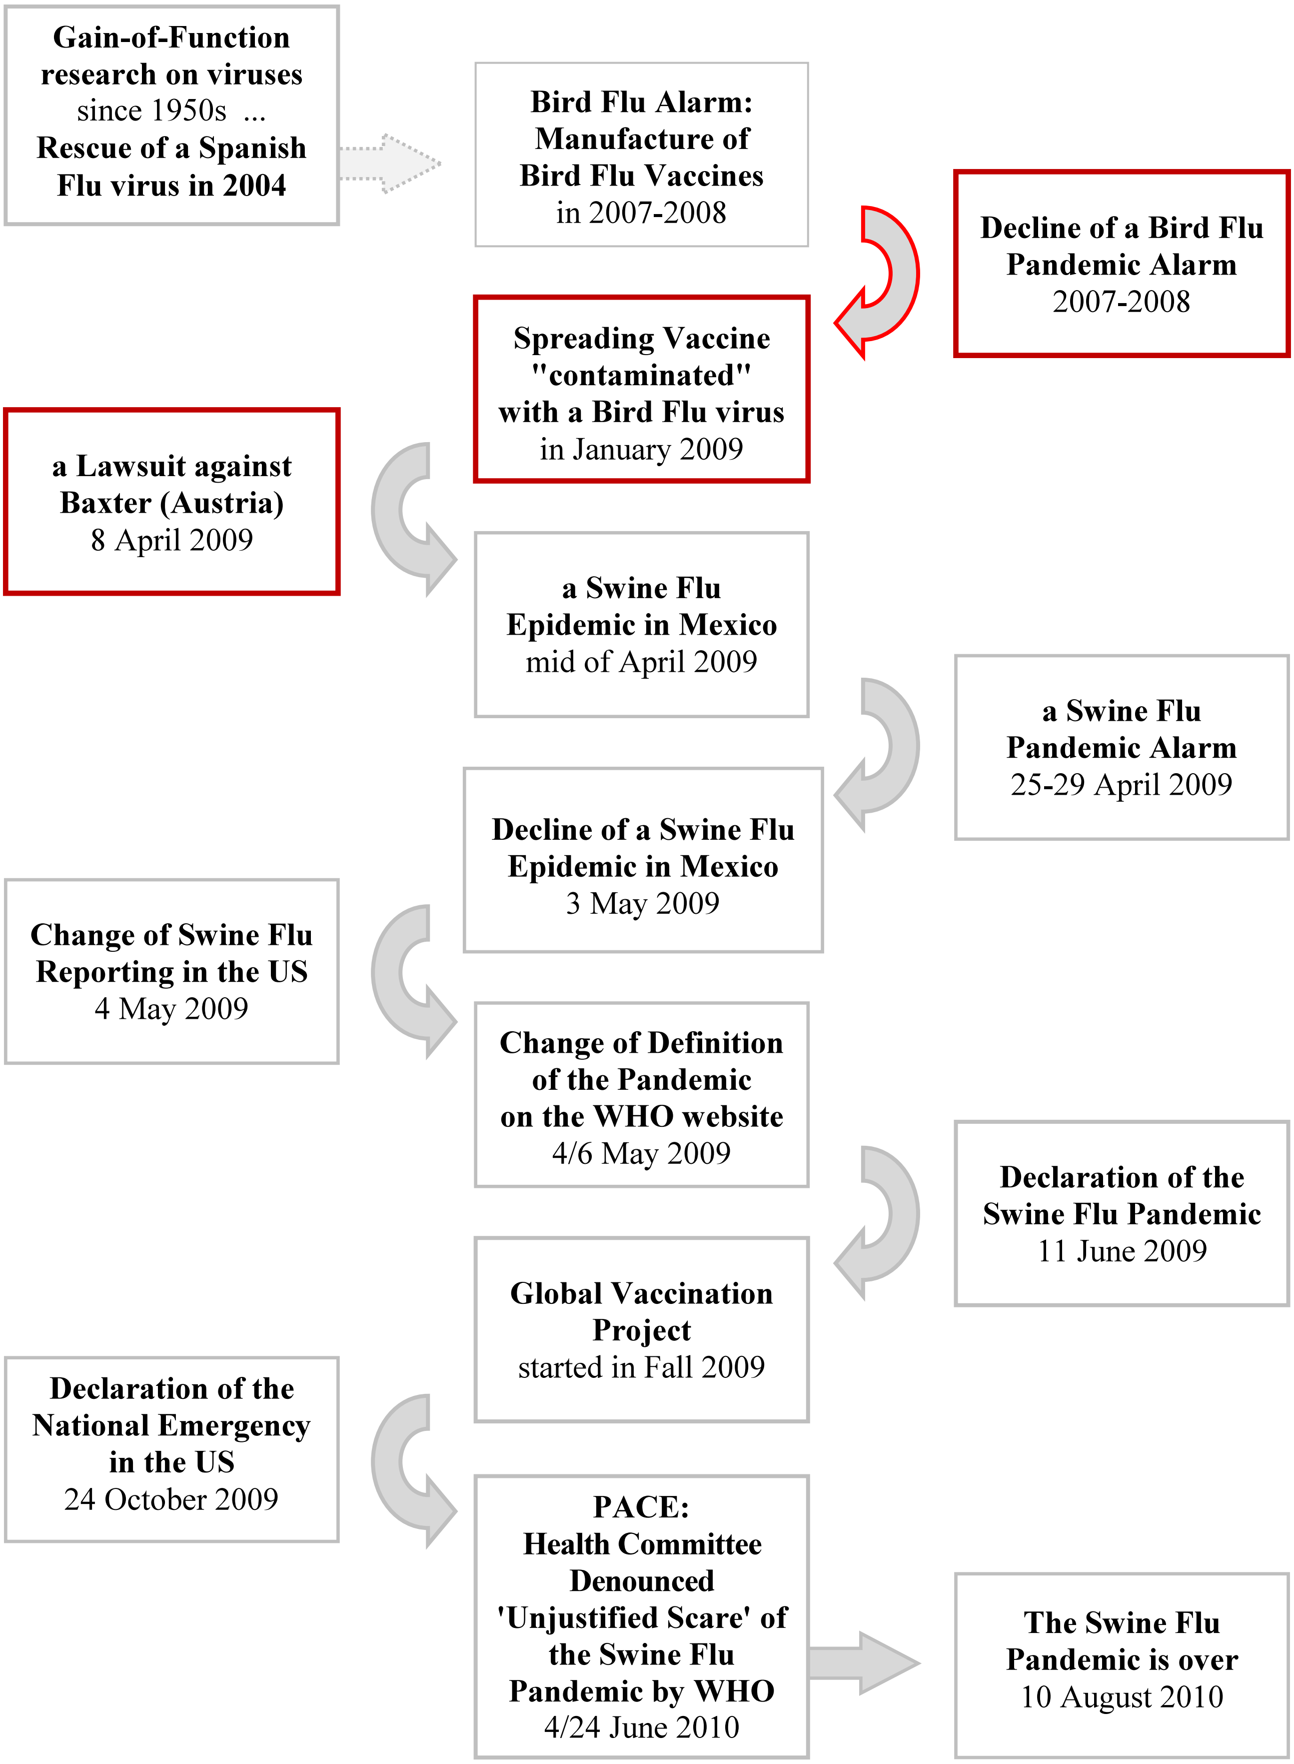
Poultry World, 8 April 2009
https://www.poultryworld.net/home/poland-bird-flu-vaccine-scam/

Three doctors and six nurses accused of having tested a vaccine against bird flu on nearly 200 patients without their knowledge went on trial in northern Poland.

The accused health workers have been charged with “fraud, creating false documents and delivering health care without authorisation” to 196 patients, according to judge Piotr Szadkowski of the Torun region.

All nine accused pleaded not guilty, however, if found guilty each health worker could be sentenced to up to 10 years in jail.

It has been reported that the medical personnel are charged with administering a vaccine banned in Poland against the deadly H5N1 strain of bird flu that can be transmitted to humans. Further reports state that the patients were paid for the vaccines.



They allegedly led their patients, many of them poor and homeless, to believe they were being vaccinated against ordinary flu.

'Flu fatigue' sets in among scientists after global spread of virus slows

The Globe and Mail (The Canadian Press), 1 January 2009
https://www.theglobeandmail.com/news/national/flu-fatigue-sets-in-among-scientists-after-global-spread-of-virus-slows/article1145766/

Five years after the avian influenza strain H5N1 started killing poultry and people in Southeast Asia, researchers still don't know what to make of the dangerous and unpredictable virus.

After cutting an ever-widening swath through poultry flocks and infecting - and killing - mounting numbers of people in Asia, the Middle East and Africa, the virus seemed almost to take a breather in 2008. The year that just ended saw fewer recorded human cases than any since 2003, when this cycle of H5N1 activity began. It raises the question: Is H5N1 on the wane?

Sadly, science knows too little about how flu viruses emerge, spread and jump - or don't jump - from one species to the next to answer that question. Given the knowledge gap, scientists are still pushing for pandemic preparedness.

"Whether or not H5N1 virus is going to cause a human pandemic - nobody can predict that," says Tim Uyeki, deputy chief of influenza surveillance and prevention for the U.S. Centers for Disease Control.

"I believe it's still a threat. But it's not the only threat," he adds, noting a two-month-old Chinese girl was hospitalized in Hong Kong last month with an H9N2 avian flu infection.

Whatever the uncertainty about H5N1, one thing is clear. A fog of exhaustion has settled over the influenza science community as well as the public health officials who have been slaving over pandemic plans. A healthy portion of the broader public is probably sick to death of the subject, too.

"I think flu fatigue is certainly a phrase which is thrown around a fair amount in the past several months or past year or so," admits Keiji Fukuda, head of the World Health Organization's global influenza program. "In stepping back after going through three or four years of working really hard, I think that there is a genuine sense of 'Wow! We have been pushing so hard and we are tired of that'."

After a peak of 115 human cases and 79 deaths in nine countries in 2006, human infections declined to 88 cases and 59 deaths in 2007. In 2008, only 40 human cases and 30 deaths were reported, from six countries.

Experts can only guess at why that is. "It could be just a cyclical thing," says Maria Zambon, head of the respiratory viruses unit of Britain's Health Protection Agency. "I would be cautious, I think about ... inferring long-term trends from actually reasonably limited data."

Dr. Fukuda says studies haven't shown that the virus has fundamentally changed, so the best guess is that the reason for the decline in cases probably rests with human behaviour. Efforts to eradicate infected poultry have improved, and countries that use poultry vaccine may be lowering the number of times people come in contact with the viruses as a result.

Dr. Uyeki suggests other possibilities. As the problem has seemed to wane, so has attention on it. That could be translating into more lax surveillance for new cases. Doctors could be less likely to suspect and test for H5N1 infection, attributing illness to myriad other potential causes.

It's clear the threat of a flu pandemic - caused by H5N1 or H9N2 or one of a multitude of other influenza viruses - remains. But it's also clear there are a vast number of other health problems competing for funding in highly challenging economic times.

It is a concern, Dr. Fukuda admits. "If we begin to withdraw our attention and move our attention to something else which is completely different, then we really stand to lose a lot of the work which has been built up over the past four years. To do this over and over again is truly ... it's like being Sisyphus," he says, referring to the Greek myth of a man condemned to a task that can never be completed.

Kein Vogelgrippefall in Wien

OTS, 11 Februaty 2009
https://www.ots.at/presseaussendung/OTS_20090211_OTS0073/kein-vogelgrippefall-in-wien

Wien (OTS) - Am vergangenen Montag wurden im Wiener Otto-Wagner-Spital 18 Mitarbeiterinnen eines externen Unternehmens ambulant behandelt, da vorerst nicht ausgeschlossen werden konnte, dass sie im Rahmen ihrer Arbeit mit einem Vogelgrippe-Erreger in Kontakt gekommen seien. Bei keinem der umfassenden Tests wurde eine Infektion festgestellt.****

Darüber hinaus wurden die PatientInnen umgehend mit einer Grippe-Vorsorge b71ehandelt. "Weder für die Patientinnen und Patienten noch für Personen, die mit ihnen in Kontakt waren, bestand eine Gefährdung. Selbstverständlich haben wir aber alle zuständigen Behörden informiert", erklärte Dr.in Susanne Drapalik von der Generaldirektion der Spitäler der Stadt Wien. (Schluss) cl

Baxter admits contaminated seasonal flu product contained live bird flu virus

The Canadian Press, 26 February 2009
https://web.archive.org/web/20090304160508/http://www.google.com/hostednews/canadianpress/article/ALeqM5iV_RT6oBK3tOhtsWf5pnu5OIby9w

The company that released contaminated flu virus material from a plant in Austria confirmed Friday that the experimental product contained live H5N1 avian flu viruses.

And an official of the World Health Organization's European operation said the body is closely monitoring the investigation into the events that took place at Baxter International's research facility in Orth-Donau, Austria.

"At this juncture we are confident in saying that public health and occupational risk is minimal at present," medical officer Roberta Andraghetti said from Copenhagen, Denmark.

"But what remains unanswered are the circumstances surrounding the incident in the Baxter facility in Orth-Donau."

The contaminated product, a mix of H3N2 seasonal flu viruses and unlabelled H5N1 viruses, was supplied to an Austrian research company. The Austrian firm, Avir Green Hills Biotechnology, then sent portions of it to sub-contractors in the Czech Republic, Slovenia and Germany.

The contamination incident, which is being investigated by the four European countries, came to light when the subcontractor in the Czech Republic inoculated ferrets with the product and they died. Ferrets shouldn't die from exposure to human H3N2 flu viruses.

Public health authorities concerned about what has been described as a "serious error" on Baxter's part have assumed the death of the ferrets meant the H5N1 virus in the product was live. But the company, Baxter International Inc., has been parsimonious about the amount of information it has released about the event.

On Friday, the company's director of global bioscience communications confirmed what scientists have suspected.

"It was live," Christopher Bona said in an email.

The contaminated product, which Baxter calls "experimental virus material," was made at the Orth-Donau research facility. Baxter makes its flu vaccine -- including a human H5N1 vaccine for which a licence is expected shortly – at a facility in the Czech Republic.

People familiar with biosecurity rules are dismayed by evidence that human H3N2 and avian H5N1 viruses somehow co-mingled in the Orth-Donau facility. That is a dangerous practice that should not be allowed to happen, a number of experts insisted.

Accidental release of a mixture of live H5N1 and H3N2 viruses could have resulted in dire consequences.

While H5N1 doesn't easily infect people, H3N2 viruses do. If someone exposed to a mixture of the two had been simultaneously infected with both strains, he or she could have served as an incubator for a hybrid virus able to transmit easily to and among people.

That mixing process, called reassortment, is one of two ways pandemic viruses are created.

There is no suggestion that happened because of this accident, however.

"We have no evidence of any reassortment, that any reassortment may have occurred," said Andraghetti.

"And we have no evidence of any increased transmissibility of the viruses that were involved in the experiment with the ferrets in the Czech Republic."

Baxter hasn't shed much light – at least not publicly – on how the accident happened. Earlier this week Bona called the mistake the result of a combination of "just the process itself, (and) technical and human error in this procedure."

He said he couldn't reveal more information because it would give away proprietary information about Baxter's production process.

Andraghetti said Friday the four investigating governments are co-operating closely with the WHO and the European Centre for Disease Control in Stockholm, Sweden.

"We are in very close contact with Austrian authorities to understand what the circumstances of the incident in their laboratory were," she said.

"And the reason for us wishing to know what has happened is to prevent similar events in the future and to share lessons that can be learned from this event with others to prevent similar events. ... This is very important."

Jane Burgermeister, an Austrian investigative reporter, filed criminal charges in April against Baxter AG and Avir Green Hills Biotechnology of Austria for producing contaminated bird flu vaccine, alleging this was a deliberate act to cause and profit from a pandemic

Criminal charges against
Baxter AG,
Baxter International and
Avir Green Hill Biotechnology AG,

For developing, manufacturing, disseminating, and releasing a biological weapon of mass destruction, on Austrian soil between December 2008 and February 2009; With the intention of causing a global bird flu pandemic virus and of intending to profit from that same pandemic, in an act that Violates Laws on International Organised Crime and Genocide.

Charges filed against Baxter and Avir

PATENTSTORM

Genetically Engineered Swine Influenza Virus and Uses Thereof
US Patent Application 20090010962

Patentstorm.us, Application Filed on 1 June 2005; Published on 8 January 2009
https://web.archive.org/web/20091103075557/http://www.patentstorm.us/applications/20090010962/claims.html

Inventors: Peter Palese, Adolfo Garcia-Sastre, Richard J. Webby, Juergen A. Richt, Robert G. Webster, Kelly M. Lager.

1. An attenuated swine influenza virus comprising a mutation in a swine influenza NS1 gene that diminishes the ability of the NS1 gene product to antagonize the cellular interferon response, and permits the attenuated virus, at a multiplicity of infection of 0.001, to grow to titers between approximately 3 fold to approximately 7 fold lower than wild-type swine influenza in pig cells, as determined approximately 5 days post-infection when propagated under the same conditions.
2. The attenuated swine influenza virus of claim 1, wherein the attenuated virus is genetically engineered.
3. The attenuated swine influenza virus of claim 1, wherein the attenuated virus is a mutagenized virus or reassortant.
4. The attenuated swine influenza virus of claim 2, wherein the attenuated virus is a chimeric virus that expresses a heterologous sequence.
5. The attenuated swine influenza virus of claim 2, wherein the attenuated virus is a chimeric virus that expresses a tumor antigen.
6. The attenuated swine influenza virus of claim 2, wherein the attenuated virus is a chimeric virus that expresses an epitope of a foreign pathogen.
7. The attenuated swine influenza virus of claim 1, wherein pig cells are PK(D1) cells, PK(15) cells, PK13 cells, NSK cells, LLC-PK1 cells, LLC-PK1A cells, ESK-4 cells, ST cells, PT-K75 cells, PK-2a/CL 13 cells or SJPL cells.
8. (canceled)
9. The attenuated swine influenza virus of claim 2, wherein the mutation is a deletion at the carboxy terminus of the NS1 gene.
10. (canceled)
11. An attenuated swine influenza virus comprising a modified NS1 gene, wherein the attenuated swine influenza virus is TX/98/del 126, TX/98/del 99 or TX/98/del 73.
12. An attenuated swine influenza virus having an altered interferon antagonist phenotype, wherein said virus comprises a mutation in the NS1 gene resulting in a deletion of between the 105 carboxy terminal amino acid residues and the 160 carboxy terminal amino acid residues of NS1.
13. The attenuated swine influenza virus of claim 12, wherein the virus is attenuated by a mutation in the NS1 gene resulting in a deletion of all of the amino acid residues of NS1 except amino acid residues 1-95, amino acid residues 1-90, amino acid residues 1-85, amino acid residues 1-80, amino acid residues 1-75, amino acid residues 1-73, amino acid residues 1-70, amino acid residues 1-65, or amino acid residues 1-60, and wherein the amino terminal amino acid is number 1 and the mutation in the NS1 gene confers an altered interferon antagonist phenotype.

Leadership in Immunization: The relevance to Japan of the U.S.A. experience of the Centers for Disease Control and Prevention (CDC) and the Advisory Committee on Immunization Practices (ACIP)

Abstract

Immunization is one of the most effective public health interventions available. However, the difference of how recommendations are established influence the utilization of the vaccine and the number of patients with vaccine preventable diseases (VPDs). In this paper, we compared and highlighted the difference of the situation of the immunization program in Japan and the United States in terms of structure of policy setting system. Since the disease epidemiology clearly indicates that the US has better control of VPDs over Japan, we considered the advantage of development of a comparable vaccine policy setting system of the US in Japan.

Bill Zeeble

6.7 million in grants slated for DISD and other schools

KERA News, 22 January 2009 at 7:58 AM CST
https://www.keranews.org/texas-news/2009-01-22/6-7-million-in-grants-slated-for-disd-and-other-schools
http://stream.publicbroadcasting.net/production/mp3/kera/local-kera-816551.mp3

Dallas, TX – Dallas, Fort Worth and other Texas school districts will share nearly 7 million dollar in grants from the Bill and Melinda Gates Foundation. The money should help more high school students go to college. KERA's Bill Zeeble has more.

6.7 million dollars from the Gates Foundations and others will fund research to improve teacher and student performance. The Texas High School Project, run out of Dallas, will get some of the money. In turn, it'll work with DISD and some other big city districts in a pilot project.

It's designed to speed up educational research in urban high schools. Faster access to rapidly changing information is the goal. The payoff's designed to help more high school students stay on track for college. The announcement's expected later this morning at DISD's W.T. White high school.

World Health Organization

WHO Immunization Funding Shortfalls
4th Global Immunization Meeting

New York, 17-19 February 200936
https://web.archive.org/web/20090328102937/http://www.who.int/immunization/funding/en/index.html
https://centerforvaccineethicsandpolicy.net/2009/03/09/who-immunization-funding-shortfalls-4th-global-immunization-meeting-new-york-17-19-february-2009/

WHO summarized presentations made at the 4th Global Immunization Meeting, held in New York, 17-19 February 2009, focused on funding shortfalls in WHO's current annual budget for immunization. The budget is about US$140 million, and main contributors to the 2008-09 budget include:
- the Bill & Melinda Gates Foundation;
- the GAVI Alliance;
- the governments and aid agencies of Canada and the United States of America;
- Johns Hopkins University;
- the Measles Partnership;
- PATH; and
- UNICEF.

During recent years, direct financial support for WHO's immunization work has decreased, with "increasing specificity of funds." The projected budget required for 2010-11 is US$210 million. Of this amount, there is a funding gap of US$109 million, or 52%. Since 2002, on average only 80% of WHO's immunization budget has been met each year. This has "led to challenges in fulfilling core functions in the area of immunization."

In 2007-2008, "various critical activities were not implemented due to the persistence of funding gaps. Updated recommendations for the production, control and evaluation of a number of existing vaccines could not be developed, resulting in a subsequent delay in their prequalification and a potential shortage in their availability. Funding gaps also impacted the evaluation of pneumococcal vaccines as well as the provision of technical support to countries, particularly in the WHO African Region."

The structure of WHO's immunization budget "has become such that today donors providing direct support are committed, but few in number, with the funds that they provide highly specified, leaving little flexibility. These factors do not allow WHO to allocate resources for immunization optimally and are impacting upon WHO's ability to deliver on its global immunization mandate. Increased direct, flexible funding from a greater number of donors would improve WHO's ability to deliver on core immunization functions."

IFPMA

Authoritative New Study Reveals Global Pandemic Influenza Vaccine Capacity

IFPMA, 24 February 2009

https://web.archive.org/web/20090414035541/https://www.ifpma.org/News/NewsReleaseDetail.aspx?nID=11559

Geneva & Chicago. – Vaccine manufacturers have substantially increased their capacity to produce pandemic influenza vaccines during the past two years, according to a new study by Oliver Wyman, an international strategy consulting firm. Importantly, this study arrived at capacity estimate numbers that the global health community agrees upon, after considerable prior debate.

Conducted in collaboration with the World Health Organization (WHO) and The International Federation of Pharmaceutical Manufacturers & Associations (IFPMA)1, the new study finds that while capacity is increasing, it would not be sufficient to meet the global need for emergency production of pandemic influenza vaccines at the time of a pandemic. However, the study notes that current and future surplus capacity could support the production of billions of doses of H5N1 influenza vaccine prior to a pandemic for stockpiling efforts and other utilization.

"We found that considerable progress has been made to enhance the production capacity of pandemic influenza vaccine," said Adam Sabow, partner at Oliver Wyman who led the study. "While capacity still falls short of global need during a pandemic, the surplus capacity during the inter-pandemic period creates opportunities for preparedness efforts. For example, we are working with the WHO to design a global H5N1 vaccine stockpile. If demand does not exist to utilize this excess capacity, however, manufacturers are likely to rationalize some of it, creating further shortages at the time of a pandemic."

IFPMA Director General Alicia D. Greenidge said, "This study advances our understanding of the world's ability to address pandemic influenza, and demonstrates the progress made by our member companies in developing new vaccine technologies and expanding production facilities. Our member companies are committed to working with the WHO and countries to ensure that we make the best use of the surplus capacity to prepare for a pandemic. The findings suggest that the early use of stockpiled H5N1-based vaccines, followed by pandemic vaccines as soon as these become available, offers a realistic strategy to address this significant threat."

The new Oliver Wyman study provides a number of further insights:

- Pandemic influenza vaccine production capacity has increased by 300 percent over the last two years, largely driven by improvements in production yields and dosage-sparing technologies.

- With current technology, doses of vaccine tailored to the actual pandemic influenza strain will not be available until four months after identification of that strain by the WHO due to the technical lead time required to adapt the strain for vaccine production, manufacture vaccine, and distribute product.

- In the base (most likely) case2, manufacturers could produce 2.5 billion doses of pandemic vaccine in the 12 months following receipt of the production strain, requiring 4 years to satisfy global demand. In the best case, 7.7 billion doses could be produced in the first 12 months, requiring 1 ½ years to satisfy global demand.

- This capacity is expected to rise to 5 - 14.5 billion doses over the next five years. The resulting time to meet global demand would be reduced to between 2½ years (in the base case) and 1 year (in the best case).

- Surplus capacity (above current seasonal influenza and stockpile demand) currently exists to produce 2.5 billion annual doses of H5N1 vaccine prior to a pandemic. This surplus capacity is expected to rise to between 2.6 and 5.4 billion doses per year over the next 5 years.

Oliver Wyman initiated this study in 2008 in cooperation with the WHO and the IFPMA, with funding from the Bill & Melinda Gates Foundation.

1 Oliver Wyman also consulted with 11 other current or potential influenza vaccine manufacturers in developing countries which are not members of the IFPMA.

2 The "base" and "best" cases are based on different assumptions relating to a number of factors, including the level of demand for seasonal influenza and H5N1 vaccine in the inter-pandemic period, the yields that can be attained, the level of antigen-sparing achievable and the degree of rationalization of traditional egg-based vaccine production capacity as new cell-based capacity comes on line. In both cases, effective coverage is calculated based on 2 doses per person, for a global population of 6.7 billion.

About the IFPMA

The International Federation of Pharmaceutical Manufacturers & Associations is the global non-profit NGO representing the research-based pharmaceutical, biotech and vaccine sectors. Its members comprise leading international companies and national and regional industry associations covering developed and developing countries.

Cincinnati Children's

Children's Hospital receives $6.7 million grant from Gates Foundation to study influenza vaccine in pregnant women in Asia

Cincinnati Children's Hospital Medical Center, 26 February 2009

https://web.archive.org/web/20090306040202/http://www.cincinnatichildrens.org/about/news/release/2009/gates-foundation-gives-grant-02-23-09.htm

Cincinnati Children's Hospital Medical Center has received a $6.7 million grant from the Bill & Melinda Gates Foundation to help prevent flu in pregnant women and their infants in rural areas around the world.

Most childhood deaths occur in the first hours and months of life when infants are most susceptible to infections. In developing countries, where many births happen at home, protecting these infants is a challenge. Maternal immunization, which is routinely used in developing countries to prevent tetanus in infants, could also offer us a tool to help mothers protect their infants against influenza in this vulnerable time.

Researchers led by the Cincinnati Children's Division of Global Health will expand on a recent study (also supported by a Gates Foundation grant) showing that influenza vaccine not only prevents pregnant women from getting the flu, but also protects their infants. The new study, to be conducted in Asia, will evaluate the safety and effectiveness of maternal flu vaccination in areas with limited medical resources.

"We have already shown, with the earlier first randomized trial in an urban setting, that the influenza vaccine protects both mothers and their children," says Mark Steinhoff, MD, director of the Division of Global Health. That study, named Mother's Gift, was published in the Oct. 9, 2008, issue of The New England Journal of Medicine. "This new, larger field study will help us demonstrate the full effect of the flu vaccination in low-resource areas."

Flu vaccine is already recommended and used in pregnant women in the US and Canada. This will be the first step in providing that same opportunity to women in the developing world. The study will also help researchers understand the effect that vaccinating mothers has on unvaccinated family members. Studies conducted in the US have shown that vaccinating one family member also provides protection to unvaccinated family members, increasing the benefits of vaccination.

Dr. Steinhoff with colleagues from Johns Hopkins and the University of Washington will carry out the study in rural areas of Bangladesh or Nepal. The study of 1,500 women will take five years to complete.

Dr. Steinhoff said the study could have worldwide implications. "If the flu vaccine has as great an effect in rural settings as in urban ones, the data will be globally relevant and useful to countries considering new vaccine policies."

Cincinnati Children's Hospital Medical Center is one of America's top three children's hospitals for general pediatrics and is highly ranked for its expertise in digestive diseases, respiratory diseases, cancer, neonatal care, heart care and neurosurgery, according to the annual ranking of best children's hospitals by U.S. News & World Report. One of the three largest children's hospitals in the U.S., Cincinnati Children's is affiliated with the University of Cincinnati College of Medicine and is one of the top two recipients of pediatric research grants from the National Institutes of Health.

The present invention provides a method for the manufacture of a preparation comprising virus antigens comprising a) inoculation of cells with infectious virus in a fluid,
b) propagation of said virus in said cells,
c) collecting said propagated virus,
d) inactivating said collected virus, and
e) treating said inactivated virus with a detergent, resulting in a preparation comprising viral antigens.

Open letter to G20 from the GAVI Alliance and the Global Fund

GAVI, 2 April 2009
https://www.gavi.org/news/media-room/open-letter-g20-gavi-alliance-and-global-fund

On the eve of the G20 meeting in London on April 2, 2009, Dr Julian Lob-Levyt, Chief Executive Officer of the GAVI Alliance and Professor Michel Kazatchkine, Executive Director of The Global Fund wrote an open letter inviting G20 leaders to increase investments in improving healthcare for the world's poor despite the global economic crisis

Geneva, 2 April 2009 - As you prepare for the G20 meeting in London next week, we would like to draw your attention to the unprecedented opportunity to improve global health that lies before us.

Over the past eight years we have seen a dramatic scale-up of investments to improve health for the world's poor. Those investments have been transformed into dramatic successes in the fight against the diseases of poverty. Between programmes supported by GAVI and the Global Fund alone, seven million deaths have either been averted or prevented. Other bilateral and multilateral efforts can show that their support has enabled similar results. With a concerted effort we can jointly ensure that the ambition to meet the Millennium Development Goals (MDGs) can be realised.

The G20 is meeting at a time of extraordinarily difficult challenges. the economic crisis that has engulfed the world is threatening to wipe out decades of hard-earned progress in reducing poverty. Relatively small reductions in financing could have dramatic negative effects on health services and lead to a loss of momentum that could take decades to repair. As so often before, it is the poorest, particularly women and children, who will bear the brunt of this crisis.

Increasing investments in health is an effective way to extend a security net to the world's poorest in times of crisis and assist developing countries in overcoming the economic hardships they are facing. If resources for development are to become more scarce, health investments have shown to be efficient and provide a measurable and cost-effective return on investments.

Over the past few years, we have learned valuable lessons. We can now expand the experiences in fighting specific diseases into programmes to reduce child mortality more generally and to improve women's health. Investments in new vaccines to prevent pneumonia and diarrhoea – the two largest child killers – will have a significant impact on MDG4. Investments in proven prevention and treatment technologies can have a dramatic impact on the AIDS, TB and malaria burden.

We are building a body of knowledge about what works in strengthening health systems to ensure a balanced, sustainable delivery of health services in a developing-country context. Through the International Health Partnership we are putting the OECD's principles of aid effectiveness into practice. The experience in institutions tailored to finance performance, such as GAVI and the Global Fund, provide important lessons in other fields of finance for development.

We look forward to building on the successes of the past years, and continuing the progress towards a world where we can bring millions out of poverty and accelerate development and prosperity by reducing the burden of infectious and vaccine-preventable diseases.

Now is the moment to invest in health. It works. It saves millions of lives.

Yours sincerely

Julian Lob-Levyt Chief Executive Officer of the GAVI Alliance

Professor Michel Kazatchkine Executive Director of The Global Fund

National Immunization Advisory Committees of the World Health Organization's European Region

Vaccine, 8 April // 21 May 2009; 27(24):3131-6.
doi: 10.1016/j.vaccine.2009.03.052. Epub 2009 Apr 8. PMID: 19446182
https://www.sciencedirect.com/science/article/abs/pii/S0264410X09004745

Abstract

This study sought to understand the prevalence, structure and decision-making process of national immunization advisory committees (IACs) among the 53 member countries of the World Health Organization (WHO)'s European region. Of the 47 countries responding to the electronically administered questionnaire, 37 (72%) have an IAC. The majority of committees have a legislative basis while just over half have formal terms of reference. Fewer than half have experts in health economics. The vast majority of countries do not allow the public to attend committee meetings nor distribute publicly the minutes of their meetings. Countries should partner with financial experts early in the process of immunization policy decision-making and should examine their policies regarding conflicts of interest and public access to meetings, as financial strategy and public trust are essential to the successful implementation of new vaccines.

Introduction

In 1974, the World Health Organization (WHO) initiated the Expanded Programme on Immunisation (EPI) with the goal to make vaccines available to all children throughout the world. The EPI was designed to provide guidance and support to improve vaccine delivery. A standardized immunization schedule was established on the basis of a review of immunological data. In the late 1980s, hepatitis B and haemophilus influenzae, type b (Hib) vaccines were added to the EPI's list of recommended vaccines. However, despite widespread morbidity and mortality related to these diseases, few countries worldwide implemented these vaccines. With higher use among wealthier countries, low uptake was attributed to economic constraints [1]. Since that time, new financing mechanisms have been developed through large donors to remove these financial barriers resulting in wider uptake, however, still not at the pace desired [2], [3].

With the recent release of several new vaccines and even more in development, the focus of international infectious disease control specialists has shifted to identifying other barriers in the implementation of new vaccines and to the maintenance of national childhood immunization programs. One area of interest is on the decision-making process within national immunization programs and the individuals central to the process.

Many developing countries have established an Interagency Coordinating Committee (ICC) to meet a requirement for financial support from the Global Alliance for Vaccines and Immunizations (GAVI) fund [4]. While the goal of the ICC is to bring together domestic agencies and international donors and advisors to coordinate efficient and effective use of resources [5], these committees are often not designed to address the technical aspects of the nation's immunization program.

Separate and distinct from the ICC, technical Immunization Advisory Committees (IACs) are used by many nations to determine the specific vaccines recommended for use in a particular country. These committees generally bring together a panel of experts to access the wide spectrum of issues involved in the decision to recommend a vaccine. The charge of these committees may include additional responsibilities such as information dissemination, advocacy and oversight of immunization programs.

A recent study [6] of IACs in 10 large industrialized nations in Western Europe revealed significant variation in the composition, process for decision-making and authority of these committees. For example, some committees made decisions through member voting while others operated by consensus. The variation was often a function of the political, social and economic environment in which the committee and the specific government operated.

Many countries in the WHO's European Region are now developing their own IACs. The findings from the 10 industrialized nations present only a limited view of the range of IAC functions currently in place across this region that is diverse both economically and politically. The 53 countries of this region extend from Western Europe to western Asia and include newly independent states of the former Soviet Union. The total expenditure on health as a percentage of the gross domestic product for this region varied from 11.3% (Switzerland) to 3.4% (Azerbaijan) in 2006 [7]. As such, a broader review of the different models of such committees would be helpful in understanding the options available to developing programs and in the assessment of the structure of existing programs. Thus, we studied the current status, composition and processes of IACs across the WHO's European Region.

Novavax Announces Preclinical Study Demonstrating that a Virus-like Particle Vaccine Provided Protection Against H1N1 and H5N1

Fierce BioTech, 16 April 2009, 10:41am
https://www.fiercebiotech.com/biotech/novavax-announces-preclinical-study-demonstrating-a-virus-like-particle-vaccine-provided

NOVAVAX Announces Publication of a Preclinical Study Demonstrating that a Virus-like Particle Vaccine Provided Protection Against Highly Pathogenic H1N1 and H5N1 Influenza Strains.
H1N1 Virus-like Particle (VLP) Vaccine Candidate Based on the 1918 Spanish Influenza Strain Protected Mice and Ferrets Against the Spanish Flu and Highly Pathogenic H5N1 Bird Flu

Rockville, Md., April 14 /PRNewswire-FirstCall/ -- Novavax, Inc. (NASDAQ: NVAX) today reported preclinical study results showing that an investigational H1N1 virus-like particle (VLP) vaccine based on the 1918 Spanish influenza strain protected against both the Spanish flu and a highly pathogenic H5N1 avian influenza strain. The study, published in the March 25, 2009 online issue of the Journal of Virology, was conducted by scientists from the Centers for Disease Control and Prevention (CDC) in Atlanta, GA and Novavax under a Collaborative Research and Development Agreement.

Novavax scientists designed and produced a recombinant VLP vaccine candidate against the 1918 H1N1 influenza strain. This 1918 influenza strain was responsible for more than 50 million deaths worldwide during the great Spanish flu pandemic. Mice and ferrets were vaccinated with VLPs by one of two routes: either by standard intramuscular injection or by administering a small drop of the VLP vaccine in the nose (intranasal immunization). All of the 1918 VLP-immunized animals were protected when exposed to a lethal dose of the 1918 influenza virus, regardless of the route by which the vaccine was administered. Remarkably, animals immunized by the intranasal route were also protected against a lethal dose of a contemporary, highly pathogenic avian influenza subtype H5N1 virus strain, isolated from a fatal human case in 2004 (A/Vietnam/1203/2004 strain).

The H1N1 VLP vaccine candidate was made up of the hemagglutinin (HA), neuraminidase (NA), and matrix 1 (M1) proteins from 1918 Spanish influenza virus strains. These proteins, which were produced in insect cells, formed three-dimensional structures that mimic the 1918 pandemic influenza virus but without the genetic material needed for replication. The mechanism of action by which this H1N1 VLP vaccine candidate provided broad cross-protection is under further study, but the scientists described preliminary evidence that antibody cross-reactivity between the HA and possibly NA proteins of the H1N1 and H5N1 influenza were important.

"Unlike other non-live influenza vaccines, the VLPs are uniquely positioned to stimulate immunity through multiple mechanisms," said Dr. Penny Heaton, Chief Medical Officer at Novavax. "First, they contain HA protein that is the same structure as the live virus, which may stimulate HA antibodies of several types that not only prevent the virus from attaching to cells but also prevent the virus from fusing with cells. Second, the VLPs contain NA which may stimulate production of antibody that prevents spread of the virus down the respiratory tract. Finally, the structure of the HA and NA proteins and the way in which they are embedded in lipids on the surface of the VLP may activate the innate immune system providing protection against both the H1N1 and H5N1 strains," said Dr. Heaton.

Although cross protection against influenza strains of the same hemagglutinin or HA type has been achieved through the use of vaccines with adjuvants (e.g., cross-protection against H5N1 A/Vietnam and A/Indonesia strains), protection against strains with different HA types, as shown in this study, has not been reported. Cross-protection against different HA types is highly desirable for pandemic influenza vaccine candidates because it is not possible to predict the strain that may be responsible for the next pandemic with today's technology. A broadly cross-protective vaccine would be ideal for stockpiling in that it could be administered during the first wave of the pandemic while waiting for manufacture of vaccine specific to the pandemic strain.

Dr. Gale Smith, Vice President of Vaccine Development at Novavax, said, "The discovery that a VLP-based influenza vaccine candidate created through cell-based recombinant technology has the potential to protect against diverse strains of influenza has significant implications for both pre-pandemic and pandemic preparedness. A broadly protective vaccine administered prior to and during the first wave of a pandemic could prevent widespread morbidity and mortality from a newly emerged pandemic influenza strain and allow time for the development of strain-specific vaccines."

About Novavax

Novavax, Inc. is a clinical-stage biotechnology company creating novel vaccines to address a broad range of infectious diseases worldwide using advanced proprietary VLP technology. The company produces these VLP based, potent, recombinant vaccines utilizing new, and efficient manufacturing approaches. The Company has VLP vaccine candidates against seasonal influenza and potential pandemic influenza strains in phase II clinical development.

This report describes the second of two preclinical studies of Novavax's investigational H5N1 pandemic influenza vaccine announced this year that have shown different approaches to achieving broad protection against diverse influenza strains. As announced in February, a VLP vaccine with an HA based on several H5 strains showed broad cross-protection against different H5 strains. In the current study, an alternative route of administration resulted in cross-protection against different HA types. Novavax has shown in clinical trials that an H5N1 VLP candidate vaccine given by intramuscular injection is well tolerated and immunogenic in humans. Preclinical research on alternative pandemic influenza VLP vaccine approaches is expected to continue.

Additional information about Novavax is available at www.novavax.com and in the company's various filings with the Securities and Exchange Commission.

Forward Looking Statement

Statements herein relating to future financial or business performance, conditions or strategies and other financial and business matters, including expectations regarding clinical developments, safety, efficacy and potency of our vaccines, and supply availability are forward-looking statements within the meaning of the Private Securities Litigation Reform Act. Novavax cautions that these forward-looking statements are subject to numerous assumptions, risks and uncertainties, which change over time. Factors that may cause actual results to differ materially from the results discussed in the forward-looking statements or historical experience include risks and uncertainties, including the failure by Novavax to secure and maintain relationships with collaborators; risks relating to the early stage of Novavax's product candidates under development; uncertainties relating to commencing clinical trials and their outcome; risks relating to the supply and commercialization, if any, of Novavax's proposed product candidates; dependence on the efforts of third parties; dependence on intellectual property; competition for clinical resources and patient enrolment from drug candidates in development by other companies with greater resources and visibility, and risks that we may lack the financial resources and access to capital to fund our operations.

Further information on the factors and risks that could affect Novavax's business, financial conditions and results of operations, is contained in Novavax's filings with the U.S. Securities and Exchange Commission, which are available at http://www.sec.gov. Baxter to work to contain Mexico flu outbreak

Chicago Breaking News // Chicago Tribune, 25 April 2009
https://web.archive.org/web/20090428154047/http://www.chicagobreakingnews.com/2009/04/baxter-to-pursue-swine-flu-virus-to-control-mexico-outbreak.html

Deerfield-based medical product giant Baxter International Inc. is working with the World Health Organization on a potential vaccine to curb the spread of the swine flu outbreak in Mexico, the company confirmed today.

Baxter, which has a growing vaccine business, has worked with foreign countries in the past to develop vaccines for the H5N1 virus commonly known as bird flu. Baxter has a cell-based technology that allows the company to more rapidly produce vaccines in the event of a pandemic than a decades-old method that uses eggs to process vaccines and can take weeks or even months longer.

"Upon learning about the swine flu outbreak in Mexico yesterday, Baxter requested a virus sample from WHO to do laboratory testing for potentially developing an experimental vaccine," company spokesman Christopher Bona told the Tribune this afternoon. "Baxter has research and development and manufacturing pandemic planning expertise to rapidly develop candidate vaccines against potentially emerging influenza viruses."

In the past, Baxter has developed vaccines and worked with countries to stockpile vaccines even while they undergo experimental testing. The idea behind the government stockpiles, in the case of the bird flu, for example, is to prepare against outbreak.

The company would not say whether the U.S. or other countries have contacted Baxter. Other companies, too, develop vaccines and have been used to stockpile vaccines. It's unclear whether other vaccine makers have also contacted the WHO.

Because it's so early in the vaccine development process, Baxter would not estimate on when a candidate vaccine would emerge for potential use.

The Mexican government is working to control a swine flu outbreak that has killed more than 65 people and potentially infected more than 1,000 in recent weeks, according to government and news reports.

Swine flu: Baxter seeks swine flu sample to begin work on vaccine: Deerfield-based Baxter has a speedier way to make vaccines than old method

Chicago Tribune, 27 April 2009;
https://web.archive.org/web/20090427195727/http://www.chicagotribune.com/business/chi-baxter-swine-flu-27-apr27,0,3579388.story

With world health officials worried about the global outbreak of another deadly virus, Deerfield-based Baxter International Inc. once again finds itself involved in the action.

Baxter confirmed over the weekend that it is working with the World Health Organization on a potential vaccine to curb the deadly swine flu virus that is blamed for scores of deaths in Mexico and has emerged as a threat in the U.S.

Baxter, which has an emerging vaccine business, has worked with the U.S. and foreign countries in the past to develop vaccines for the H5N1 virus commonly known as bird flu.

Baxter has a cell-based technology that allows the company to produce vaccines more rapidly in the event of a pandemic than a decades-old method that uses eggs and can take weeks or months longer. Although the egg-based method has produced safe and effective vaccines, analysts say Baxter's method can cut production times in half compared with the older process.

"Upon learning about the swine flu outbreak in Mexico, Baxter requested a virus sample from WHO to do laboratory testing for potentially developing an experimental vaccine," company spokesman Christopher Bona told the Tribune.

In the past, Baxter has developed vaccines and worked with countries to stockpile vaccines even while they undergo experimental testing.

The idea behind the government stockpiles, in the case of the bird flu, for example, is to prepare against outbreak.

As of Sunday, Baxter would not say whether the U.S. or other countries have contacted the company to develop a stockpile against swine flu. Other companies, too, develop vaccines and have been used to stockpile vaccines.

The effort to ensure a safe vaccine supply and an adequate number of manufacturers has taken on greater importance in recent years.

Three years ago, for example, the Bush administration awarded about $1 billion to vaccine makers as a way to increase and speed production, particularly after the spread of bird flu.

Several vaccine makers, including Baxter, GlaxoSmithKline and others, were awarded multimillion-dollar contracts.

Baxter, working with another company, was awarded a five-year contract to develop both seasonal and pandemic vaccines using its cell-based technology, according to terms of the deal disclosed in May 2006.

Over the years, Baxter has worked with governments around the world to develop and produce vaccines to protect against infectious disease or potential threats from bioterrorism.

In the wake of the terrorist attacks on Sept. 11, 2001, Baxter worked with British biotech company Acambis to supply stockpiles of a smallpox vaccine. In 2003, Baxter was awarded a U.S. contract to develop and produce a vaccine against severe acute respiratory syndrome (SARS) for use by the National Institutes of Health in early human clinical trials.

And in 2005, Baxter worked with another company to develop a "plasma-based therapeutic targeted for use in individuals who may be exposed to nerve gas poisons," the company said at the time.

Because it's so early in the swine flu vaccine development process, Baxter would not estimate when a vaccine might be ready.

Push is on for vaccine against fatal swine flu:
Deerfield-based Baxter seeks sample to test

Chicago Tribune, 27 April 2009, p. 1.19

Baxter to Develop Swine Flu Vaccine Despite Bird Flu Scandal
The fox has been given the duty of guarding the henhouse

InforWars, 27 April 2009
https://web.archive.org/web/20100106114432/http://www.prisonplanet.com/baxter-to-develop-swine-flu-vaccine-despite-bird-flu-scandal.html
https://inthesenewtimes.com/2009/04/28/baxter-to-develop-swine-flu-vaccine-despite-bird-flu-scandal/

A U.S. based pharmaceutical company that just weeks ago was involved in a scandal involving vaccines tainted with deadly avian flu virus has been chosen to head up efforts to produce a vaccine for the Mexican swine flu that has seemingly migrated into the U.S. and Europe.

Baxter confirmed over the weekend that it is working with the World Health Organization on a potential vaccine to curb the deadly swine flu virus that is blamed for scores of deaths in Mexico and has emerged as a threat in the U.S., reports the Chicago Tribune.

Baxter has previously worked with governments all over the globe to develop and produce vaccines to protect against infectious disease or potential threats from bioterrorism. After 9/11 Baxter helped supply stockpiles of a smallpox vaccine and in 2003 the company was contracted to develop a vaccine to combat the SARS virus. In 2006 the UK Government announced plans designed to inoculate every person in the country with Baxter's vaccines in the event of a flu pandemic.

However, Baxter has a very recent and most disturbing connection to flu vaccines.

As reported by multiple sources last month, including the Times of India, vaccines contaminated with deadly live H5N1 avian flu virus were distributed to 18 countries last December by a lab at an Austrian branch of Baxter.

It was only by providence that the batch was first tested on ferrets in the Czech Republic, before being shipped out for injection into humans. The ferrets all died and the shocking discovery was made.

Czech newspapers immediately questioned whether the events were part of a conspiracy to deliberately provoke a pandemic, following up on accusations already made by health officials in other countries.

Initially, Baxter attempted to stonewall questions by invoking "trade secrets" and refused to reveal how the vaccines were contaminated with H5N1. After increased pressure they then claimed that pure H5N1 batches were sent by accident.

Since the probability of mixing a live virus biological weapon with vaccine material by accident is virtually impossible, this leaves no other explanation than that the contamination was a deliberate attempt to weaponize the H5N1 virus to its most potent extreme and distribute it via conventional flu vaccines to the population who would then infect others to a devastating degree as the disease went airborne.

The fact that Baxter mixed the deadly H5N1 virus with a mix of H3N2 seasonal flu viruses is the smoking gun. The H5N1 virus on its own has killed hundreds of people, but it is less airborne and

more restricted in the ease with which it can spread. However, when combined with seasonal flu viruses, which as everyone knows are super-airborne and easily spread, the effect is a potent, super-airbone, super deadly biological weapon.

Indeed, some have already suggested that the current scare could represent the use of such a weapon.

Now it has been announced that Baxter is seeking a sample of the potentially lethal never before seen form of swine/avian/human flu virus in order to assist the World Health Organization in developing a new vaccine, reaping billions in the process.

Why should Baxter be trusted, when they have already been proven to be at the very least criminally negligent, and at worst a prime suspect in attempting to carry off one of the most heinous crimes in the history of mankind?

The company has already put the safety of the entire human race at risk, and now, just a few weeks later, we're expected to invest our confidence in them and take their shots with a smile and a still tongue?

As Mike Adams of Natural News has commented, "If you mail an envelope full of anthrax to your Senator, you get arrested as a terrorist. So why is Baxter – which mailed samples of a far more deadly viral strain to labs around the world – getting away with saying, essentially, 'Oops?' "

WHO officials are reportedly still closely monitoring the investigation into Baxter's contaminated flu vaccines, seemingly they are not too concerned. Perhaps we should be.

How to Deal with Swine Flu: Heeding the Mistakes of 1976

Time, 27 April 2009
https://web.archive.org/web/20090524061940/http://www.time.com/time/health/article/0,8599,1894129,00.html

In February 1976, an outbreak of swine flu struck Fort Dix Army base in New Jersey, killing a 19-year-old private and infecting hundreds of soldiers. Concerned that the U.S. was on the verge of a devastating epidemic, President Gerald Ford ordered a nationwide vaccination program at a cost of $135 million (some $500 million in today's money). Within weeks, reports surfaced of people developing Guillain-Barré syndrome, a paralyzing nerve disease that can be caused by the vaccine. By April, more than 30 people had died of the condition. Facing protests, federal officials abruptly canceled the program on Dec. 16. The epidemic failed to materialize.

Medical historians and epidemiologists say there are many differences between the relatively benign 1976 outbreak and the current strain of swine flu that is spreading across the globe. But they also say the decisions made in the wake of the '76 outbreak – and the public's response to them – provide a cautionary tale for public health officials, who may soon have to consider whether to institute draconian measures to combat the disease.

"I think 1976 provides an example of how not to handle a flu outbreak, but what's interesting is that it made a good deal of sense at the time," says Hugh Pennington, an emeritus professor of virology at Britain's University of Aberdeen. Pennington points out that conventional wisdom in 1976 held that the 1918 flu pandemic – which started among soldiers and eventually killed as many as 40 million – was the result of swine flu (scientists now know it was in fact a strain of bird flu). Despite modern advances in microbiology, today's health officials still make decisions in a "cloud of uncertainty," Pennington says. "At the moment, our understanding of the current outbreak is similarly limited. For example, we don't yet understand why people are dying in Mexico but not elsewhere."

In a quickly evolving situation, deciding what public health orders to make becomes as much an art as a science, and can often stir debate. On Monday, for example, health officials in Europe advised citizens to cancel all nonessential trips to Mexico and the U.S. The U.S. Centers for Disease Control and Prevention (CDC) said that advisory was too severe. Such decisions, difficult enough to make on purely medical grounds, become even more complicated when they involve politics. In 1976, President Ford's vaccine program came during an election cycle, and some historians believe he was swayed as much by a desire to display strong leadership as by the advice of health experts. (Read "Swine Flu: 5 Things You Need to Know About the Outbreak.")

Howard Markel, director of the Center for the History of Medicine at the University of Michigan and a historical consultant to the CDC on flu pandemics, says the most vexing decision facing health officials is when to institute mass vaccination programs. Vaccines carry risks of complications, leading to agonizing ethical dilemmas. In 1976, Ford offered indemnity to the vaccine manufacturers.

But according to reports, President George W. Bush decided in 2002 not to administer a nationwide smallpox vaccination program – despite Vice President Dick Cheney's belief that doing so was a prudent counterterrorism step – because it could have resulted in dozens of deaths (the smallpox vaccine kills between 1 and 2 people per million people inoculated).

Markel says the political climate in the U.S. is much less combustible today than in the post-Watergate era, when Ford faced a skeptical public. Even so, he says, citizens still need to trust that the government is working for the greater good. He says, "The good news is that our surveillance, methodology and public health professionals have never been better. But we are human and mistakes may be made – as happened with the 1976 swine flu affair – and we may jump the gun in the hope of preserving life. The current outbreak is a situation in flux. The American public has to be forgiving and patient and do [their] part too."

Paul Joseph Watson

Time Magazine Preps Americans For Mandatory Vaccinations:
Says public should "trust" government
when it institutes draconian measures to deal with pandemic

Prison Planet 28 April 2009
https://web.archive.org/web/20090918200352/http://www.prisonplanet.com/time-magazine-preps-americans-for-mandatory-vaccinations.html

Time Magazine's coverage of the swine flu scare has a noticeable subplot – preparing Americans for draconian measures to combat a future pandemic as well as forcing them to accept the idea of mandatory vaccinations.

In an article entitled How to Deal with Swine Flu: Heeding the Mistakes of 1976, the piece discusses how dozens died and hundreds were injured from vaccines as a result of the 1976 swine flu fiasco, when the Ford administration attempted to use the infection of soldiers at Fort Dix as a pretext for a mass vaccination of the entire country.

Despite acknowledging that the 1976 farce was an example of "how not to handle a flu outbreak," the article still introduces the notion that officials "may soon have to consider whether to institute draconian measures to combat the disease."

Later we discover exactly what this will entail, namely "when to institute mass vaccination programs," according to Howard Markel, director of the Center for the History of Medicine at the University of Michigan and a historical consultant to the CDC on flu pandemics.

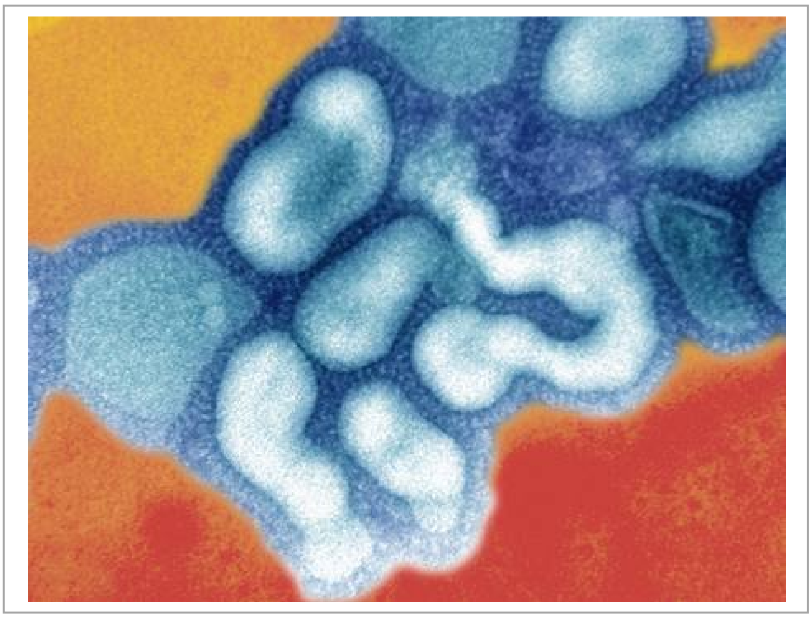
Markel notes that the less politically combustible situation in America today compared to the post-Watergate era of Ford would make such draconian measures more achievable.

"Even so, he says, citizens still need to trust that the government is working for the greater good," adds the article. "The American public has to be forgiving and patient and do [their] part too," according to Markel.

Americans would indeed have to be very trustworthy and ultimately forgiving in taking a vaccine by government decree manufactured by a company that was been caught red-handed contaminating their vaccines with far deadlier viruses than swine flu.

As we reported yesterday, Baxter International confirmed over the weekend that it is working with the World Health Organization on a potential vaccine to curb the deadly swine flu virus that is blamed for scores of deaths in Mexico and has emerged as a threat in the U.S., reports the Chicago Tribune.

As reported by multiple sources last month, including the Times of India, vaccines contaminated with deadly live H5N1 avian flu virus were distributed to 18 countries last December by a lab at an Austrian branch of Baxter.



Since the probability of mixing a live virus biological weapon with vaccine material by accident is virtually impossible, this leaves no other explanation than that the contamination was a deliberate attempt to weaponize the H5N1 virus to its most potent extreme and distribute it via conventional flu vaccines to the population who would then infect others to a devastating degree as the disease went airborne.

These are the people we are supposed to "trust" and "forgive" according to Time Magazine and Markel when the federal government breaks down our door, guns drawn and dripping needle in hand.

Vakcíny proti prasečí chřipce dodá firma, která poslala nakažené vzorky

iDNES, 5. května 2009 (5 May 2009), 18:05
https://www.idnes.cz/zpravy/domaci/vakciny-proti-praseci-chripce-doda-firma-ktera-poslala-nakazene-vzorky.A090505_165450_domaci_adb

Odstupující vláda kývla na nabídku farmaceutické firmy Baxter, že Česku dodá vakcínu proti prasečí chřipce. Topolánkův kabinet se pro Baxter rozhodl jednomyslně i přesto, že firmu provází skandál, kdy v únoru do Česka poslala testovací vakcíny kontaminované virem ptačí chřipky.

Vláda si vybrala farmaceutickou firmu Baxter.
Bez výběrového řízení a přes její únorový skandál. | foto: Profimedia.cz

Zdroj: "Rozhodnutí padlo," řekl už v pondělí premiér v demisi Mirek Topolánek s tím, že víc prozradit nemůže. Jeho kabinet projednal nabídku v takzvaném vyhrazeném režimu, takže se veřejnost nedozví, jak rozhodl a kterou firmu vybral. - čtěte Vakcína proti prasečí chřipce možná vznikne v Česku

Podle informací iDNES.cz je to firma Baxter. Návrh, aby Česko uzavřelo kupní smlouvu s farmaceutickou firmou, přednesla na pondělním jednání vlády ministryně zdravotnictví Daniela Filipiová.

Stát si tak zarezervoval 12 milionů vakcín proti prasečí chřipce. Jen za rezervační poplatek bude muset firmě po dobu pěti let platit 300 milionů, prozradil iDNES.cz zdroj z vlády, který si nepřál být jmenován.

Téma na zasedání vlády vyvolalo velkou debatu, ale kabinet nakonec nabídku jednomyslně schválil. A to i přes riziko, že vakcíny nakonec nebudou využity. Nemůžeme si dovolit to nekoupit, shodli se nakonec ministři.

"Je sebevražedné to neodsouhlasit. Je to ročně jeden třicetikorunový poplatek na občana," nechal se na vládě slyšet ministr práce a sociálních věcí Petr Nečas, jak iDNES.cz prozradil vládní zdroj.

Kabinet si výběr Baxteru bez výběrového řízení odůvodnil tím, že pouze tato firma dovede vakcínu vyrobit do třech měsíců. Jiné farmaceutické společnosti by potřebovaly dvojnásobnou dobu, argumentoval podle zdroje před ministry hlavní hygienik Michael Vít.

Ministryně zdravotnictví Daniela Filipiová odmítla informaci potvrdit. "Nevím, o čem mluvíte," řekla iDNES.cz. "Nevím, odkud tu informaci máte. Já se vám k tomu rozhodně vyjadřovat nebudu," dodala.

"Řeknu jen to, že vláda včera jednala a přijala takové opatření, že v případě opravdu velkého rizika pandemie chřipky H1N1 bude pro občany této země zajištěna vakcinace," uvedla.
Kontaminovaná zásilka putovala i do dalších zemí

Americká firma Baxter, která má svou nejmodernější pobočku v obci Bohumil u Kostelce nad Černými lesy, ale nemá v Česku zrovna dobré jméno. V únoru totiž do Česka poslala testovací materiál nakažený virem ptačí chřipky H5N1. - o skandálu čtěte zde

Virus, který je považován za možnou biologickou zbraň, totiž uchovává ve své rakouské pobočce v Orthu. Právě odsud poslali farmaceuti Baxteru do Česka kontaminované vzorky, aniž by někdo z rakouské či české strany informoval úřad, který má na starosti biologickou bezpečnost.

Čeští vědci zjistili až náhodou, že vakcína obsahuje nebezpečný virus. A jen shodou náhod nebyl nikdo nakažen. Kromě Česka putovala zásilka i do dalších zemí, virus se tak ocitl najednou nekontrolovaně na několika místech v Evropě.

"Vakcína nakažená ptačí chřipkou se testovala v samotném Rakousku, České republice, Německu a ve Slovinsku. A všude se tento problém vyskytl," řekl už tehdy hlavní hygienik.

GlaxoSmithKline update:
A (H1N1) influenza vaccine development

London UK & Philadelphia US, GSK, 15 May 2009

https://web.archive.org/web/20090515213253/http://www.gsk.com/media/pressreleases/2009/2009_pressrelease_10054.htm

- GSK has received orders from several governments aiming to stockpile a new candidate A (H1N1) adjuvanted influenza vaccine as a precautionary measure
- Company to manufacture the new vaccine, once virus seed is made available by the WHO
- Seasonal influenza vaccine production continues

GSK is committed to supporting governments and health authorities around the world to respond to the emergence of the new A (H1N1) influenza strain.

Since the outbreak, the company has been in continuous discussions with governments and public health authorities, including the WHO, the US Centers for Disease Control and Prevention, the US Department of Health and Human Services and the European Centre for Disease Prevention and Control to help develop appropriate options to respond to the emergence of the new A (H1N1) influenza strain.

A (H1N1) influenza candidate adjuvanted vaccine

GSK expects to manufacture a candidate A (H1N1) adjuvanted influenza vaccine once virus seed is made available by the WHO. The first doses of the vaccine are expected to be available four to six months later, subject to regulatory approval.

- The vaccine will comprise antigen of the recently isolated A (H1N1) influenza strain and also contain GSK's proprietary adjuvant system AS03. An adjuvant system can be added to the antigen at time of administration. In clinical studies using the H5N1 influenza strain, an adjuvanted formulation has been shown to stimulate a higher immune response while using a smaller amount of antigen as compared to a formulation without adjuvant. The adjuvant system therefore helps to increase the number of vaccine doses that can be produced.[1] In addition, in clinical studies with the H5N1 influenza strain, the adjuvanted vaccine demonstrated the potential to provide protection even if the influenza strain drifts (changes slightly).[2,3]
- The new candidate vaccine will require regulatory approval. In 2008, GSK received a European licence fora pandemic vaccine based on a 'mock-up' dossier. This approval, which was based on data involving the H5N1 influenza strain, is expected to enable faster registration of this new A (H1N1) influenza vaccine and is currently being discussed with European regulatory authorities.
- To date, GSK has received interest from several governments aiming to stockpile the new candidate adjuvanted vaccine as a precautionary measure.

These include:

- Supplying the UK Government with 60 million doses of the candidate A (H1N1) adjuvanted influenza vaccine.
- The French Government intend to purchase 50 million doses of the candidate A (H1N1) influenza vaccine.

- The Government of Belgium intend to purchase 12.6 million doses of the candidate A (H1N1) influenza vaccine in order to stockpile and to protect, when needed, the total Belgian population.
- An agreement with the Government of Finland to supply 5.3 million doses of H1N1 antigen, which is expected to be used in conjunction with the government's existing stockpile of GSK's adjuvant system.

- GSK has made substantial investments to expand capacity for its adjuvant system. As part of the company's commitment to maximising global manufacturing capacity of a pandemic vaccine, GSK is ready to engage in discussions with companies and governmental agencies that can combine the adjuvant system with alternatively sourced antigen.
- GSK is committed to addressing the needs of developing countries with use of this candidate adjuvanted vaccine. GSK will convert its intended donation to the WHO of 50 million doses of H5N1 pre-pandemic vaccine to the new candidate A (H1N1) adjuvanted influenza vaccine once production begins.
- In the future, as capacity increases, GSK will supply the candidate A (H1N1) adjuvantedinfluenza vaccine to developing countries under a tiered-pricing policy based on World Bank classifications and GAVI eligibility.

Seasonal influenza vaccine

GSK will continue to produce its seasonal influenza vaccine for the 2009/2010 Northern Hemisphere influenza season as planned and expects to complete production of this vaccine by the end of July. The company also continues to supply seasonal vaccine for use in the Southern Hemisphere as it enters the winter season this year.

GlaxoSmithKline – one of the world's leading research-based pharmaceutical and healthcare companies – is committed to improving the quality of human life by enabling people to do more, feel better and live longer. For further information please visit www.gsk.com

Notes to Editors

- Adjuvants, from the Latin word adjuvare meaning 'to help', are compounds used to enhance a vaccine's ability to elicit a strong, durable, protective immune response making them more effective. Until recently, vaccine research and development focused nearly exclusively on the antigen, the target molecule that is selected to trigger a specific immune response in the body to protect against a particular disease. It is now widely accepted that adjuvants can also contribute substantially to the immune response induced by a vaccine.

- GSK is continuing discussions with other governments and public health authorities to increase production and supply of its anti-viral medication, *Relenza*. *Relenza* can both treat influenza (flu, infection caused by influenza virus) and reduce the chance of getting flu in the community and household settings. The flu is a highly contagious and potentially fatal disease caused by influenza types A and B. While some antiviral medications only protect against influenza A, *Relenza* is effective against both influenza A and B. *Relenza* is approved for the prophylaxis and treatment of influenza in children and adults.

- *Relenza* is an inhaled medicine delivered as a dry powder through a device called a *Diskhaler* to the surface of the upper respiratory tract, and may shorten the amount of time a person is sick if used within two days of onset of illness. *Relenza* belongs to a group of medicines called neuraminidase inhibitors. These medications attack the influenza virus itself – not just the symptoms – and prevent it from spreading inside your body.

WHO sees 4.9 billion pandemic flu shots in best-case

Reuters, 19 May 2009, 7:39 P.M.
https://www.reuters.com/article/us-flu-who-idUSTRE54H1XO20090519

Geneva (Reuters) – Vaccine makers could produce 4.9 billion pandemic flu shots per year in the best-case scenario, the head of the World Health Organization said on Tuesday, as rich and poor countries grappled over limited supplies.

WHO Director-General Margaret Chan told reporters after her meeting with 30 pharmaceutical companies that "there are a lot of unanswered questions" about how many vaccines could be made to protect vulnerable people from the new H1N1 virus.

"That is a very optimistic maximum capacity," she said of the 4.9 billion estimate, which would be significantly lower if people need more than one injection to gain immunity against the strain or if seasonal flu vaccine-making continues.

Bringing a new pandemic vaccine to market – if it goes ahead – is expected to take 4-6 months, according to the WHO. It must be tested first on ferrets and then on humans in clinical trials before regulatory authorities can approve it.

U.N. Secretary-General Ban Ki-moon told the news briefing that while the newly-discovered virus strain now appears mild, it needs to be closely watched as it spreads around the world and starts to afflict impoverished countries.

"We may be in a grace period with H1N1 but we are still in the danger zone," Ban said.

Earlier on Tuesday, the United Nations chief said it was essential for drugmakers to work with governments to avert the worst potential impacts of the flu, which has killed 79 people and infected nearly 10,000.

"Partnerships with the private sector are absolutely vital," he told representatives of the WHO's 193 member governments gathered in Geneva, urging them to think beyond their borders in their response to the H1N1 strain.

Though most people infected so far have experienced mild symptoms similar to the common flu, pregnant women and people with HIV/AIDS, diabetes and other health problems appear to be vulnerable to more severe effects like pneumonia.

Health experts have said weather could affect the continued spread of the virus, with more cases expected as countries in the southern hemisphere move into winter. Flu viruses typically thrive in cold and dry environments.

Ready to Produce

Pharmaceutical executives taking part in Tuesday's vaccines meeting at the WHO's Geneva headquarters said they were primed to ramp up production of H1N1 vaccines if needed, and would await more directions about how to balance their output.

"Our companies stand ready to produce H1N1 vaccines when the recommendation comes from the WHO," the International Federation of Pharmaceutical Manufacturers and Associations said.

Six companies have pledged to make 10 percent of the vaccine they produce available for distribution to poor countries, and eight are in talks about donations, said Gelmer Leibbrandt, general manager of Schering-Plough's Nobilon.

Chan said that vaccine makers have shown "a very serious commitment" to help the international community prepare for a pandemic of flu, which could be mild in its effects to start and become more severe as it circles the globe.

Questions remain about whether an H1N1-only vaccine is needed in the near-term – especially if its production cuts the world's supply of injections for seasonal flu, which kills up to 500,000 people a year and causes severe illness in millions.

U.S. Health and Human Services Secretary Kathleen Sebelius said pharmaceutical companies should ramp up their production of seasonal flu shots and then later switch to pandemic injection making "if that is necessary."

"There is still so much uncertainty about this virus that it is really premature for us to even make a determination about how many people would appropriately be vaccinated, in what order, how many doses will be required, at what point. All those discussions are still very much underway," Sebelius said.

Ban, in his remarks to the World Health Assembly, called on wealthy nations to help support poorer states fight the flu.

But one international official said he expected battles ahead as governments try to secure finite supplies of antiviral drugs and vaccines to protect their populations.

"Enabling poor countries to be able to access the various medical supplies they need is going to be a critical political and technical issue," he said. "This issue will require political attention."

The WHO has said the world is on the brink of pandemic from the H1N1 virus, which has been most prevalent in North America and begun to infect large numbers in Japan, Britain and Spain.

World now at the start of 2009 influenza pandemic

Geneva, WHO, 11 June 2009

https://www.cidrap.umn.edu/h1n1-2009-pandemic-influenza/who-declares-pandemic-novel-h1n1-virus
https://web.archive.org/web/20090611173204/http://www.who.int/mediacentre/news/statements/2009/h1n1_pandemic_phase6_20090611/en/index.html

Ladies and gentlemen,

In late April, WHO announced the emergence of a novel influenza A virus. This particular H1N1 strain has not circulated previously in humans. The virus is entirely new. The virus is contagious, spreading easily from one person to another, and from one country to another. As of today, nearly 30,000 confirmed cases have been reported in 74 countries. This is only part of the picture. With few exceptions, countries with large numbers of cases are those with good surveillance and testing procedures in place.

Spread in several countries can no longer be traced to clearly-defined chains of human-to-human transmission. Further spread is considered inevitable. I have conferred with leading influenza experts, virologists, and public health officials. In line with procedures set out in the International Health Regulations, I have sought guidance and advice from an Emergency Committee established for this purpose. On the basis of available evidence, and these expert assessments of the evidence, the scientific criteria for an influenza pandemic have been met.

I have therefore decided to raise the level of influenza pandemic alert from phase 5 to phase 6.

The world is now at the start of the 2009 influenza pandemic. We are in the earliest days of the pandemic. The virus is spreading under a close and careful watch.

No previous pandemic has been detected so early or watched so closely, in real-time, right at the very beginning. The world can now reap the benefits of investments, over the last five years, in pandemic preparedness. We have a head start. This places us in a strong position. But it also creates a demand for advice and reassurance in the midst of limited data and considerable scientific uncertainty.

Thanks to close monitoring, thorough investigations, and frank reporting from countries, we have some early snapshots depicting spread of the virus and the range of illness it can cause. We know, too, that this early, patchy picture can change very quickly. The virus writes the rules and this one, like all influenza viruses, can change the rules, without rhyme or reason, at any time.

Globally, we have good reason to believe that this pandemic, at least in its early days, will be of moderate severity. As we know from experience, severity can vary, depending on many factors, from one country to another.

On present evidence, the overwhelming majority of patients experience mild symptoms and make a rapid and full recovery, often in the absence of any form of medical treatment. Worldwide, the number of deaths is small. Each and every one of these deaths is tragic, and we have to brace ourselves to see more. However, we do not expect to see a sudden and dramatic jump in the number of severe or fatal infections.

We know that the novel H1N1 virus preferentially infects younger people. In nearly all areas with large and sustained outbreaks, the majority of cases have occurred in people under the age of 25 years.

In some of these countries, around 2% of cases have developed severe illness, often with very rapid progression to life-threatening pneumonia. Most cases of severe and fatal infections have been in adults between the ages of 30 and 50 years. This pattern is significantly different from that seen during epidemics of seasonal influenza, when most deaths occur in frail elderly people.

Many, though not all, severe cases have occurred in people with underlying chronic conditions. Based on limited, preliminary data, conditions most frequently seen include respiratory diseases, notably asthma, cardiovascular disease, diabetes, autoimmune disorders, and obesity.

At the same time, it is important to note that around one third to half of the severe and fatal infections are occurring in previously healthy young and middle-aged people.

Without question, pregnant women are at increased risk of complications. This heightened risk takes on added importance for a virus, like this one, that preferentially infects younger age groups.

Finally, and perhaps of greatest concern, we do not know how this virus will behave under conditions typically found in the developing world. To date, the vast majority of cases have been detected and investigated in comparatively well-off countries.

Let me underscore two of many reasons for this concern.

First, more than 99% of maternal deaths, which are a marker of poor quality care during pregnancy and childbirth, occurs in the developing world.

Second, around 85% of the burden of chronic diseases is concentrated in low- and middle-income countries.

Although the pandemic appears to have moderate severity in comparatively well-off countries, it is prudent to anticipate a bleaker picture as the virus spreads to areas with limited resources, poor health care, and a high prevalence of underlying medical problems.

Ladies and gentlemen,

A characteristic feature of pandemics is their rapid spread to all parts of the world. In the previous century, this spread has typically taken around 6 to 9 months, even during times when most international travel was by ship or rail. Countries should prepare to see cases, or the further spread of cases, in the near future. Countries where outbreaks appear to have peaked should prepare for a second wave of infection. Guidance on specific protective and precautionary measures has been sent to ministries of health in all countries. Countries with no or only a few cases should remain vigilant.

Countries with widespread transmission should focus on the appropriate management of patients. The testing and investigation of patients should be limited, as such measures are resource intensive and can very quickly strain capacities.

WHO has been in close dialogue with influenza vaccine manufacturers. I understand that production of vaccines for seasonal influenza will be completed soon, and that full capacity will be available to ensure the largest possible supply of pandemic vaccine in the months to come. Pending the availability of vaccines, several non-pharmaceutical interventions can confer some protection.

WHO continues to recommend no restrictions on travel and no border closures.

Influenza pandemics, whether moderate or severe, are remarkable events because of the almost universal susceptibility of the world's population to infection.

We are all in this together, and we will all get through this, together.

Thank you.

THE JOURNAL OF
LAW, MEDICINE & ETHICS

The Nuremberg Code

Law, Medicine and Healthcare, Appendix IV. Fall-Winter 1991, 19(3-4): 266
DOI: https://doi.org/10.1111/j.1748-720X.1991.tb01825.x

Appendix IV

The Nuremberg Code

1. The voluntary consent of the human subject is absolutely essential.

This means that the person involved should have legal capacity to give consent; should be so situated as to be able to exercise free power of choice, without the intervention of any element of force, fraud, deceit, duress, over-reaching, or other ulterior form of constraint or coercion; and should have sufficient knowledge and comprehension of the elements of the subject matter involved as to enable him to make an understanding and enlightened decision. This latter element requires that before the acceptance of an affirmative decision by the experimental subject there should be made known to him the nature, duration, and purpose of the experiment; the method and means by which it is to be conducted; all inconveniences and hazards reasonably to be expected; and the effects upon his health or person which may possibly come from his participation in the experiment.

The duty and responsibility for ascertaining the quality of the consent rests upon each individual who initiates, directs or engages in the experiment. It is a personal duty and responsibility which may not be delegated to another with impunity.

2. The experiment should be such as to yield fruitful results for the good of society, unprocurable by other methods or means of study, and not random and unnecessary in nature.
3. The experiment should be so designed and based on the results of animal experimentation and a knowledge of the natural history of the disease or other problem under study that the anticipated results will justify the performance of the experiment.
4. The experiment should be so conducted as to avoid all unnecessary physical and mental suffering and injury.
5. No experiment should be conducted where there is an *a priori* reason to believe that death or disabling injury will occur; except, perhaps, in those experiments where the experimental physicians also serve as subjects.
6. The degree of risk to be taken should never exceed that determined by the humanitarian importance of the problem to be solved by the experiment.
7. Proper preparations should be made and adequate facilities provided to protect the experimental subject against even remote possibilities of injury, disability, or death.
8. The experiment should be conducted only by scientifically qualified persons. The highest degree of skill and care should be required through all stages of the experiment of those who conduct or engage in the experiment.
9. During the course of the experiment the human subject should be at liberty to bring the experiment to an end if he has reached the physical or mental state where continuation of the experiment seemed to him to be impossible.
10. During the course of the experiment the scientist in charge must be prepared to terminate the experiment at any stage, if he has probably [sic] cause to believe, in the exercise of the good faith, superior skill and careful judgement required of him that a continuation of the experiment is likely to result in injury, disability, or death to the experimental subject.

The Nuremberg Code

1. *The voluntary consent of the human subject is absolutely essential.*

This means that the person involved should have legal capacity to give consent; should be so situated as to be able to exercise free power of choice, without the intervention of any element of force, fraud, deceit, duress, overreaching, or other ulterior form of constraint or coercion; and should have sufficient knowledge and comprehension of the elements of the subject matter involved as to enable him to make an understanding and enlightened decision. This latter element requires that before the acceptance of an affirmative decision by the experimental subject there should be made known to him the nature, duration, and purpose of the experiment; the method and means by which it is to be conducted; all inconveniences and hazards reasonably to be expected; and the effects upon his health or person which may possibly come from his participation in the experiment.

The duty and responsibility for ascertaining the quality of the consent rests upon each individual who initiates, directs or engages in the experiment. It is a personal duty and responsibility which may not be delegated to another with impunity.

2. The experiment should be such as to yield fruitful results for the good of society, unprocurable by other methods or means of study, and not random and unnecessary in nature.

3. The experiment should be so designed and based on the results of animal experimentation and a knowledge of the natural history of the disease or other problem under study that the anticipated results will justify the performance of the experiment.

4. The experiment should be so conducted as to avoid all unnecessary physical and mental suffering and injury.

5. No experiment should be conducted where there is an a priori reason to believe that death or disabling injury will occur; except, perhaps, in those experiments where the experimental physicians also serve as subjects.

6. The degree of risk to be taken should never exceed that determined by the humanitarian importance of the problem to be solved by the experiment.

7. Proper preparations should be made and adequate facilities provided to protect the experimental subject against even remote possibilities of injury, disability, or death.

8. The experiment should be conducted only by scientifically qualified persons. The highest degree of skill and care should be required through all stages of the experiment of those who conduct or engage in the experiment.

9. During the course of the experiment the human subject should be at liberty to bring the experiment to an end if he has reached the physical or mental state where continuation of the experiment seems to him to be impossible.

10. During the course of the experiment the scientist in charge must be prepared to terminate the experiment at any stage, if he has probable cause to believe, in the exercise of the good faith, superior skill, and careful judgment required of him, that a continuation of the experiment is likely to result in injury, disability, or death to the experimental subject.

The Nuremberg Code is the most important document in the history of the ethics of medical research.[1–6] The Code was formulated 50 years ago, in August 1947, in Nuremberg, Germany, by American judges sitting in judgment of Nazi doctors accused of conducting murderous and torturous human experiments in the concentration camps (the so-called Doctors' Trial).[7] It served as a blueprint for today's principles that ensure the rights of subjects in medical research. Because of its link with the horrors of World War II and the use of prisoners in Nazi concentration camps for medical experimentation, debate continues today about the authority of the Code, its applicability to modern medical research, and even its authorship.[1,2,4,5,8] The chief prosecutor at the Doctors' Trial, General Telford Taylor, believed that one of the three U.S. judges, Harold Sebring, was the author of the Code.[2] Two American physicians who helped prosecute the Nazi doctors at Nuremberg, Leo Alexander and Andrew Ivy, have each been identified as the Code's author.[5,8–11] A careful reading of the transcript of the Doctors' Trial, background documents, and the final judgment reveals that authorship was shared and that the famous 10 principles of the Code grew out of the trial itself.

In this article I will explain the important role that physicians had in the prosecution of the Nazi doctors and in the formulation of the Nuremberg Code and summarize how medical researchers have used the Code as a guide over the past five decades....

50 Years after Nuremberg

The Nuremberg Code has not been officially adopted in its entirety as law by any nation or as ethics by any major medical association. Nonetheless, its influence on global human-rights law and medical ethics has been profound.[6] Its basic requirement of informed consent, for example, has been universally accepted and is articulated in international law in Article 7 of the United Nations International Covenant on Civil and Political Rights (1966).[6,22] Informed consent, with specific reliance on the Nuremberg Code, is also the basis of the International Ethical Guidelines for Biomedical Research Involving Human Subjects, the most recent guidelines promulgated by the World Health Organization and the Council for International Organizations of Medical Sciences (1993).[23]

The World Medical Association, established during World War II, *has been accused of purposely trying to undermine Nuremberg in order to distance physicians from Nazi medical crimes*.[24] The election of a former Nazi physician and SS member, Hans-Joachim Sewering, to the presidency of that organization in 1992 added credibility to that accusation.[24] (Because of public criticism, Sewering later withdrew.) Nonetheless, the various versions of the Declaration of Helsinki promulgated by the World Medical Association since 1964, although attempting to have peer review supplement informed consent and even supplant it as their central principle in the context of “therapeutic research,” all implicitly acknowledge Nuremberg's authority. Both the Nuremberg Code and the Declaration of Helsinki served as models for the current U.S. federal research regulations, which require not only the informed consent of the research subject (with proxy consent sometimes acceptable, as for young children), but also prior peer review of research protocols by a committee (the institutional review board of the hospital or research institution) that includes a representative of the community.[25]

The Nuremberg Code focuses on the ***human rights*** of research subjects, the Declaration of Helsinki focuses on the obligations of physician-investigators to research subjects, and the federal regulations emphasize the obligations of research institutions that receive federal funds. Nonetheless, by insisting that medical investigators alone cannot set the rules for the ethical conduct of research, even when guided by beneficence and Hippocratic ethics, and by adopting a human-rights perspective that acknowledges the centrality of informed consent and the right of the subject to withdraw, the Nuremberg Code has changed forever the way both physicians and the public view the proper conduct of medical research on human subjects. Fifty years after Nuremberg, we recognize the human-rights legacy of the Nuremberg Code and are better able to face the critical challenge of applying the Code in its entirety and enforcing its human-rights provisions.

U.S. Department of
Health and Human Services
Enhancing the health and well-being of all Americans

Rep. Waxman, Henry A. [D-CA-24]

H.R.5546 - National Childhood Vaccine Injury Act of 1986
99th Congress (1985-1986)

Introduced 18 September 1986 // Passed House amended 14 October 1986
https://www.congress.gov/bill/99th-congress/house-bill/5546

National Childhood Vaccine Injury Act of 1986 –

Title I: Vaccines - Subtitle 1: National Vaccine Program - Amends the Public Health Service Act to establish in the Department of Health and Human Services a National Vaccine Program to:
(1) direct vaccine research and development within the Federal Government;
(2) ensure the production and procurement of safe and effective vaccines;
(3) direct the distribution and use of vaccines; and
(4) coordinate governmental and nongovernmental activities. Requires the Director of the Program to report to specified congressional committees.
Establishes the National Vaccine Advisory Committee to recommend: (1) ways to encourage the availability of an adequate supply of vaccines; and (2) research priorities.
Authorizes appropriations for FY 1987 through 1991.

Subtitle 2:
National Vaccine Injury Compensation Program - Part A: Program Requirements

Establishes the National Vaccine Injury Compensation Program as an alternative remedy to judicial action for specified vaccine-related injuries.
Prescribes the contents of any petition for compensation.
Grants U.S. district courts authority to determine eligibility and compensation. Requires the district court in which the petition is filed to designate a special master to serve as an adjunct to the court. Sets forth the responsibilities of the court.
Lists factors to be considered when determining the amount of a compensation award. Sets forth a table of injuries deemed vaccine-related for compensation purposes. Permits the Secretary of Health and Human Services to: (1) promulgate regulations to revise such table; and (2) recommend changes to the vaccines covered by the table.
Provides that compensation awarded under the Program shall be paid out of the National Vaccine Injury Compensation Trust Fund. Limits awards for actual and projected pain and suffering and emotional distress to $250,000. Prohibits awards for punitive damages.
Establishes the Advisory Commission on Childhood Vaccines to:
(1) advise the Secretary on the implementation of the Program;
(2) recommend changes to the Vaccine Injury Table; and
(3) recommend research priorities.

Part B: Additional Remedies - Sets forth procedures under which the person who filed a petition for compensation under the program may elect to file a civil action for damages.

Provides that no vaccine manufacturer shall be liable in a civil action for damages arising from a vaccine-related injury or death: (1) resulting from unavoidable side effects; or (2) solely due to the manufacturer's failure to provide direct warnings. Provides that a manufacturer may be held liable

where: (1) such manufacturer engaged in the fraudulent or intentional withholding of information; or (2) such manufacturer failed to exercise due care. Permits punitive damages in such civil actions under certain circumstances.

Part C: Assuring a Safer Childhood Vaccination Program in the United States - Requires each health care provider who administers a vaccine listed in the Vaccine Injury Table to record certain information with respect to each such vaccine. Requires each health care provider and vaccine manufacturer to report certain information to the Secretary.

Requires the Secretary to develop certain vaccine information materials for distribution to the legal representatives of any child receiving a vaccine listed in the Vaccine Injury Table.

Directs the Secretary to promote the development of safer childhood vaccines.

Sets forth recordkeeping and reporting requirements for vaccine manufacturers. Imposes civil and criminal penalties for destroying, altering, or concealing any such report or record.

Part D: General Provisions - Allows any person to commence a civil action against the Secretary where the Secretary allegedly has failed to perform a duty under this Act. Provides for judicial review of the Secretary's regulatory actions in a court of appeals of the United States.

Allows the Secretary to provide licensing for unpatented vaccines for naturally occurring human infectious diseases under certain circumstances.

Requires the Secretary to conduct studies on pertussis, rubella, and radiculoneuritis vaccines and publish the results of such studies.

Directs the Secretary to study the risks to children associated with each vaccine listed in the Vaccine Injury Table and establish guidelines respecting the administration of such vaccines. Directs the Secretary to periodically review and revise such guidelines.

Directs the Secretary to review the warnings, use instructions, and precautionary information presently used by manufacturers of vaccines listed in the Vaccine Injury Table. Directs the Secretary to require manufacturers to revise and reissue any warning, instruction, or information found inadequate.

Grants the Secretary recall authority with respect to any licensed virus, serum, toxin, antitoxin, vaccine, blood, blood component or derivative, allergenic product, or other licensed product which presents a danger to public health. Establishes civil penalties for recall violations.

Directs the Secretary to make annual reports to specified congressional committees on the impact this Act has on the supply of vaccines.

Title II: Miscellaneous - Provides that certain Federal provisions designed to reduce paperwork shall not apply to information required to carry out this Act.

A Dragon by the Tail

Holistic Pediatric Association, 7 March 2005
https://web.archive.org/web/20090304005731/http://www.hpakids.org/holistic-health/articles/183/1/A-Dragon-By-the-Tail

On the eve of an historic, billion-dollar world vaccination campaign, a leaked transcript ignites questions of vaccine safety and research corruption. Meanwhile, US senators fast-track a bill to protect vaccine manufacturers from litigation. With millions of lives at stake, and billions of dollars to loose, will a merger of philanthropy, big business and compromised science win an epic race between corporate agendas and medical ethics? In this world exclusive report, byronchild exposes how the most powerful medical research bodies in the United States compromise their vaccine safety research for vested interests, as they assist in a global vaccine policy, while a bill looms in the background to protect it all.

On January 24, 2005 – the same day the Global Alliance for Vaccines and Immunization (GAVI) announced the receipt of $750 million for its historic world vaccination campaign – seven US Senators introduced Senate Bill 3 . The bill is an unprecedented act giving comprehensive liability protections to vaccine manufacturers, restricting Freedom of Information Acts on drug/vaccine safety, and pre-empting states' rights to ban mercury from children's vaccines, all under the bill's official title: "Protecting America in the War on Terror Act of 2005".

Meanwhile in Texas, a US District Court judge has ordered the worlds' "big five" vaccine manufacturers to "produce any and all documents relating to payments made to, or stock ownership" by the seventeen members of the Institute of Medicine's Immunization and Safety Review Committee who issued a report last year denying a link between childhood vaccines and the country's autism epidemic.

The judge issued the order after receiving a leaked internal transcript in the first civil juried lawsuit against the vaccine manufacturers that allegedly proves the Institutes of Medicine's committee members "predetermined the necessity of not finding causality between vaccines and autism and/or neurological injury" in its official reports on the issue.

Judge T. John Ward also ordered the vaccine manufacturers to produce all communications with "members of the World Health Organization, the Center for Disease Control, the Food and Drug Administration, the Institute of Medicine, the Brighton Collaboration, or the Global Alliance for Vaccines and Immunization relating to the issue whether the thimerosal contained in pediatric vaccines causes autism or other neurological disorders."

The vaccine manufacturer's legal counsel balked at the amount of expense involved in producing such extensive documentation for the court; however, Judge Ward reassured the defense that the process could be useful for the more than 300 pending lawsuits waiting to be tried in the US .

Vaccine manufacturers Aventis Pasteur, Merck, GlaxoSmithKline, Wyeth and Eli Lilly and Co. are cited as defendants in the lawsuit brought by the parents of a child who developed autism after receiving mandatory routine childhood immunizations.

The same IOM reports denying a link between vaccines and the country's autism epidemic have been used:

- to endorse standardized case definitions for Adverse Events Following Immunizations for "global dissemination";
- as justification for Senate Bill 3's sweeping provisions and protections;
- as a cause for no further federal monies to be spent on research of the potential vaccine/autism link;
- as a reason to silence media inquiries into vaccine safety issues;
- and as a defense for dismissing over 4,500 petitions for vaccine injuries in a federal court.

Is it possible that a closed meeting transcript alleged as proof of a ploy to ignore vaccine risks, a near billion dollar grant for a global vaccination campaign, emerging lawsuits for vaccine injuries and a sweeping federal bill to protect vaccine manufacturers are unrelated?

Is it possible that in spite of US Congressional hearings and reports citing widespread conflicts of interest between federal policy makers and the vaccine industry that Senate Bill 3 will defy the US Constitution's provisions for state and civil rights in order to shield vaccine manufacturers from liability?

And finally, how will a world vaccine policy influenced by allegedly "predetermined" safety reports implemented through a global alliance of international governments and vaccine manufacturers with a fund of billions headquartered in Geneva, Switzerland, support or protect the health and human rights of targeted Third-World country peoples?

ASPR Administration for Strategic Preparedness & Response

Public Readiness and Emergency Preparedness (PREP) Act

ASPR, 2005/2006
https://aspr.hhs.gov/legal/PREPact/pages/default.aspx

The Public Readiness and Emergency Preparedness Act (PREP Act) authorizes the Secretary of the Department of Health and Human Services (Secretary) to issue a PREP Act declaration. The declaration provides immunity from liability (except for willful misconduct) for claims:

- of loss caused, arising out of, relating to, or resulting from administration or use of countermeasures to diseases, threats and conditions
- determined by the Secretary to constitute a present, or credible risk of a future public health emergency
- to entities and individuals involved in the development, manufacture, testing, distribution, administration, and use of such countermeasures

A PREP Act declaration is specifically for the purpose of providing immunity from liability, and is different from, and not dependent on, other emergency declarations.

COVID-19 PREP Act Declarations
The end of the COVID-19 Public Health Emergency Declaration does not automatically terminate PREP Act coverage. To learn more, view our COVID-19 PREP Act FAQs.

Public Readiness and Emergency Preparedness Act
Targeted liability protections
for pandemic and epidemic products and security countermeasures

United States Code, §247d–6d, 2005/2006
https://uscode.house.gov/view.xhtml?req=(title:42%20section:247d-6d%20edition:prelim
https://www.govinfo.gov/content/pkg/PLAW-109publ148/pdf/PLAW-109publ148.pdf

(a) Liability protections

(1) *In general*: Subject to the other provisions of this section, a covered person shall be immune from suit and liability under Federal and State law with respect to all claims for loss caused by, arising out of, relating to, or resulting from the administration to or the use by an individual of a covered countermeasure if a declaration under subsection (b) has been issued with respect to such countermeasure.

(2) *Scope of claims for loss*
(A) Loss - For purposes of this section, the term "loss" means any type of loss, including:
(i) death;
(ii) physical, mental, or emotional injury, illness, disability, or condition;
(iii) fear of physical, mental, or emotional injury, illness, disability, or condition, including any need for medical monitoring; and
(iv) loss of or damage to property, including business interruption loss.

Each of clauses (i) through (iv) applies without regard to the date of the occurrence, presentation, or discovery of the loss described in the clause.

(B) Scope - The immunity under paragraph (1) applies to any claim for loss that has a causal relationship with the administration to or use by an individual of a covered countermeasure, including a causal relationship with the design, development, clinical testing or investigation, manufacture, labeling, distribution, formulation, packaging, marketing, promotion, sale, purchase, donation, dispensing, prescribing, administration, licensing, or use of such countermeasure.

(3) *Certain conditions*
Subject to the other provisions of this section, immunity under paragraph (1) with respect to a covered countermeasure applies only if-

(A) the countermeasure was administered or used during the effective period of the declaration that was issued under subsection (b) with respect to the countermeasure;
(B) the countermeasure was administered or used for the category or categories of diseases, health conditions, or threats to health specified in the declaration; and
(C) in addition, in the case of a covered person who is a program planner or qualified person with respect to the administration or use of the countermeasure, the countermeasure was administered to or used by an individual who-
(i) was in a population specified by the declaration; and
(ii) was at the time of administration physically present in a geographic area specified by the declaration or had a connection to such area specified in the declaration.

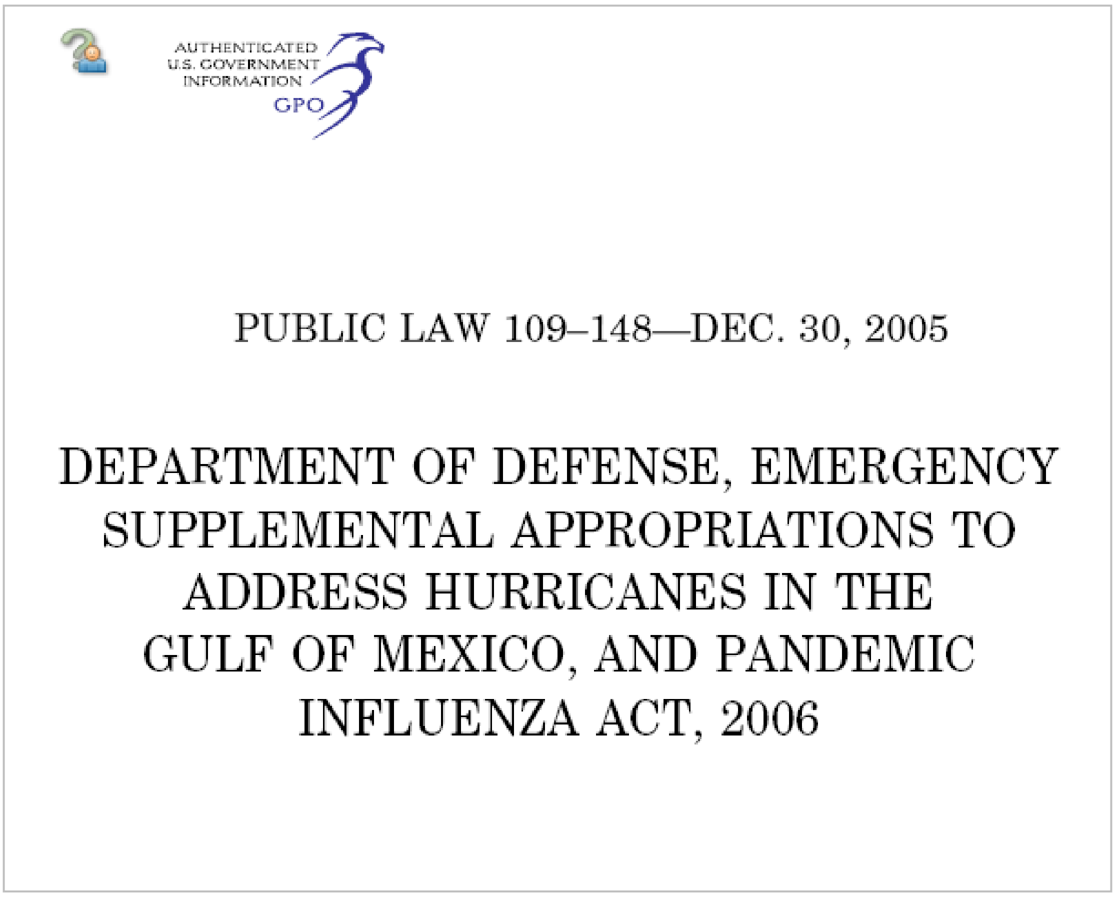
(4) *Applicability of certain conditions*

With respect to immunity under paragraph (1) and subject to the other provisions of this section:

(A) In the case of a covered person who is a manufacturer or distributor of the covered countermeasure involved, the immunity applies without regard to whether such countermeasure was administered to or used by an individual in accordance with the conditions described in paragraph (3)(C).

(B) In the case of a covered person who is a program planner or qualified person with respect to the administration or use of the covered countermeasure, the scope of immunity includes circumstances in which the countermeasure was administered to or used by an individual in circumstances in which the covered person reasonably could have believed that the countermeasure was administered or used in accordance with the conditions described in paragraph (3)(C).

(5) *Effect of distribution method*



The provisions of this section apply to a covered countermeasure regardless of whether such countermeasure is obtained by donation, commercial sale, or any other means of distribution, except to the extent that, under paragraph (2)(E) of subsection (b), the declaration under such subsection provides that subsection (a) applies only to covered countermeasures obtained through a particular means of distribution.

(6) *Rebuttable presumption*

For purposes of paragraph (1), there shall be a rebuttable presumption that any administration or use, during the effective period of the emergency declaration by the Secretary under subsection (b), of a covered countermeasure shall have been for the category or categories of diseases, health conditions, or threats to health with respect to which such declaration was issued.

(b) Declaration by Secretary

On January 24, 2005, the same day the Global Alliance for Vaccines and Immunization (GAVI) announced the receipt of $750 million for its historic world vaccination campaign, seven US Senators introduced Senate Bill 3. The bill is an unprecedented act giving comprehensive liability protections to vaccine manufacturers, restricting Freedom of Information Acts on drug/vaccine safety, and pre-empting states' to ban mercury from children's vaccines, all under the bill's official title: "Protecting America in the War on Terror Act of 2005".

The NEW ENGLAND JOURNAL of MEDICINE

Leonard H. Glantz, George J. Annas

The FDA, Preemption, and the Supreme Court

N Engl J Med 1 May 2008; 358(18): 1883-1885
DOI: 10.1056/NEJMp0802108

Everyone would like to be immune from lawsuits. Legislatures sometimes provide immunity in order to advance important social policy goals. For example, by providing health care professionals with immunity under Good Samaritan statutes, legislatures hope to encourage voluntary medical assistance in emergencies. Similarly, Congress provided immunity to *vaccine manufacturers who claimed they could not economically manufacture vaccines with the threat of liability hanging over them*.

Because providing immunity deprives injured people of their day in court, legislation that creates immunity sometimes also creates an alternative compensatory mechanism. For example, the federal law that immunized vaccine manufacturers from lawsuits created a system for the compensation of persons injured by vaccines. Nevertheless, immunity undermines the tort system's goal of deterring unreasonably dangerous actions or omissions.

When Congress creates a regulatory scheme through legislation, immunity is seldom a centerpiece. Instead, the question of immunity is usually determined by another doctrine – that of preemption. Under the U.S. Constitution's Supremacy Clause, federal laws are “supreme” over state laws: when the two conflict, the federal law rules, and the state law is unenforceable. If the two do not conflict, they can coexist – and, for example, subject those charged with drug crimes to both federal and state penalties. The Supremacy Clause also empowers the federal government to explicitly “preempt an area” over which it has authority, “completely occupying” it and depriving the states of all authority to enact and enforce laws in that area.

...

Next fall, the Court will hear a case about FDA-approved drugs (see Key Preemption Decisions of the Supreme Court).5 Because drug approval is governed by a different law that contains no explicit preemption language, Riegel provides no indication of how the Court will rule. Nonetheless, the pharmaceutical industry, with the support of the Bush administration, is arguing that once the FDA approves a drug, the preemption doctrine implicitly deprives injured persons of the opportunity to prove it was inadequately labeled. As in Riegel, acceptance of this argument would leave the injured person with no recourse.

NBC NEWS

Legal immunity set for Swine Flu Vaccine Makers

NBC News, 18 July 2009
https://www.nbcnews.com/id/wbna31971355

The last time the government embarked on a major vaccine campaign against a new swine flu, thousands filed claims contending they suffered side effects. This time, the government has already taken steps to head that off. Vaccine makers and federal officials will be immune from lawsuits that result from any new swine flu vaccine, under a document signed by Secretary of Health and Human Services Kathleen Sebelius, government health officials said Friday.

Since the 1980s, the government has protected vaccine makers against lawsuits over the use of childhood vaccines. Instead, a federal court handles claims and decides who will be paid from a special fund. The document signed by Sebelius last month grants immunity to those making a swine flu vaccine, under the provisions of a 2006 law for public health emergencies. It allows for a compensation fund, if needed.

Immunity encourages vaccine-makers

The government takes such steps to encourage drug companies to make vaccines, and it's worked. Federal officials have contracted with five manufacturers to make a swine flu vaccine. First identified in April, swine flu has so far caused at least 263 deaths, according to numbers released by the Centers for Disease Control and Prevention on Friday.

The CDC said more than 40,000 Americans have had confirmed or probable cases, but those are people who sought health care. It's likely that more than 1 million Americans have been sickened by the flu, many with mild cases.

The virus hits younger people harder that seasonal flu, but so far hasn't been much more deadly than the strains seen every fall and winter. But health officials believe the virus could mutate to a more dangerous form, or at least contribute to a potentially heavier flu season than usual.

"We do expect there to be an increase in influenza this fall," with a bump in cases perhaps beginning earlier than normal, said Dr. Anne Schuchat, director of the CDC's National Center for Immunization and Respiratory Diseases.

On Friday, the Food and Drug Administration approved the regular winter flu vaccine, a final step before shipments to clinics and other vaccination sites could begin.

The last time the government faced a new swine flu virus was in 1976. Cases of swine flu in soldiers at Fort Dix, N.J., including one death, made health officials worried they might be facing a deadly pandemic like the one that killed millions around the world in 1918 and 1919.

Thousands filed claims after 1976 campaign

Federal officials vaccinated 40 million Americans during a national campaign. A pandemic never materialized, but thousands who got the shots filed injury claims, saying they suffered a paralyzing condition called Guillain-Barre Syndrome or other side effects.

"The government paid out quite a bit of money," said Stephen Sugarman, a law professor who specializes in product liability at the University of California at Berkeley.

Vaccines aren't as profitable as other drugs for manufacturers, and without protection against lawsuits "they're saying, 'Do we need this?'" Sugarman said.

The move to protect makers of a swine flu didn't go over well with Paul Pennock, a prominent New York plaintiffs attorney on medical liability cases. The government will likely call on millions of Americans to get the vaccinations to prevent the disease from spreading, he noted.

"If you're going to ask people to do this for the common good, then let's make sure for the common good that these people will be taken care of if something goes wrong," Pennock said.

DIGITAL JOURNAL

Andrew Moran

Public Health Official: No-Fault Compensation for Swine Vaccine

Digital Journal, 21 July 2009
https://web.archive.org/web/20091116082418/http://www.digitaljournal.com/article/276290

Top Canadian public health officials are calling for no-fault compensation, which would be given to Canadians who suffer side-effects from swine flu vaccinations.

A leading Canadian public health official says Canada needs to create a no-fault compensation plan to encourage Canadians to take the H1N1 swine flu vaccination, which will be available in three to four months. The official is calling for such a measure because Canadians maybe harmed by the vaccine, which was similar to the previous swine flu vaccine, which caused paralyzed conditions.

The Canada research chair in public health at the University of Ottawa Kumanan Wilson said that the public will receive an incompletely vaccine, which will not receive the standard testing by the World Health Organization and that a compensation plan will encourage Canadians to take the flu shot.

Canada research chair in public health at the University of Ottawa David Butler-Jones said, "The more people that have immunity, the easier it is to stop."

According to CanWest News Service, who has conducted the interviews with the two health officials, states that Canada has no plans to compensate people, unlike the United States, which is false. An article posted on Digital Journal titled: Vaccine Makers Receive Immunity, vaccine developers will receive immunity, therefore, any company like Baxter cannot be held liable.

Officials who are calling for a vaccine injury program, believe that people who develop side-effects would receive faster compensation rather than going through the Canadian justice system. Currently, only Quebec has a no-fault compensation in Canada.

An expert in pandemic planning told CanWest Service, "I'm not saying we shouldn't roll out this vaccine (against H1N1 influenza). I don't know how confident we will be in its efficacy and safety at the outset, but I don't think we'll have any choice but to roll it out, because, at this point, the only way to control the spread is going to be a vaccine. But there are going to be concerns about people not wanting to take the vaccine, health-care workers in particular. We have been arguing that it needs to be complemented with a no-fault compensation program, just like in 1976, and we need to develop systems to pick up these adverse events."

During the swine flu scare in 1976, thousands of people developed Guillain-Barre syndrome and 26 people died.

Canada will protect swine flu vaccine maker from lawsuits

The Star, 30 September 2009, 02:40 PM
https://web.archive.org/web/20091004090926/http://www.thestar.com/newsfeatures/swineflu/article/703355

Canada is protecting the drugmaker of swine flu vaccine from lawsuits over potential side effects, Canada's top doctor has confirmed.

Dr. David Butler-Jones told a media teleconference Wednesday that Canada will shield Galxo SmithKline in the unlikely event there are problems with the vaccine, but it will not shield health practitioners who make mistakes in administering the shot.

"We're not obviously anticipating problems with it, but indemnification for a vaccine is important if someone does malpractice, basically injects someone the wrong way or causes harm because of their practice," he said.

"That's not a vaccine issue, it's a practice issue," he added.

The Public Health Agency of Canada had initially refused to say if Canada would shield drugmakers the way other G-8 governments have done.

Pandemic Flu and Medical Biodefense Countermeasure Liability Limitation

EveryCRSReport, 18 November 2005 – 12 February 2010
https://www.everycrsreport.com/reports/RS22327.html

Division C of P.L. 109-148 (2005), 42 U.S.C. §§ 247d-6d, 247d-6e, also known as the Public Readiness and Emergency Preparedness Act (PREP Act), limits liability with respect to pandemic flu and other public health countermeasures. Specifically, upon a declaration by the Secretary of Health and Human Services of a public health emergency or the credible risk of such emergency, Division C would, with respect to a "covered countermeasure," eliminate liability, with one exception, for the United States, and for manufacturers, distributors, program planners, persons who prescribe, administer or dispense the countermeasure, and employees of any of the above.

The exception to immunity from liability is that a defendant who engaged in willful misconduct would be subject to liability under a new federal cause of action, though not under state tort law, if death or serious injury results.

Division C's limitation on liability is a more extensive restriction on victims' ability to recover than exists in most federal tort reform statutes. However, victims could, in lieu of suing, accept payment under a new "Covered Countermeasure Process Fund," if Congress appropriates money for this fund.

The first PREP Act declaration was issued on January 26, 2007, to limit liability for the administration of the H5N1 influenza vaccine. Since then, declarations have been issued covering countermeasures against other strains of influenza (including H1N1), anthrax, botulism, small pox, and acute radiation syndrome.

Polish Health Minister [Eva Kopacz], a family doctor, tells Parliament She will not allow use of untested Swine Flu jabs: Reveals Secret contracts Violate the Law

The Flu Case, 5 November 2009, 11:59

https://web.archive.org/web/20100106085046/http://www.theflucase.com/index.php?option=com_content&view=article&id=1618%3Aupdate-polish-health-minister-a-family-doctor-tells-parliament-she-will-not-allow-use-of-untested-swine-flu-jabs-reveals-secret-contracts-violate-the-law&catid=41%3Ahighlig

The Polish Health Minister Eva Kopacz today told Parliament during a heated debate on the swine flu vaccination that she, as a qualified family doctor with more than 20 year of experience, will not authorise the use of untested vaccines on millions of people in Poland when there is inadequate information about the safety of the jabs.

She said the secret contract that the Polish government was supposed to sign with pharmaceutical companies had more than 20 clauses which are against the law.

Kopacz noted that governments in Western Europe had signed secret agreements with pharmaceutical companies, but suggested that the prosperity of the people of Poland was more important to her than the profits of Big Pharma.

She noted that there are three vaccines proposed for Poland with different types of adjuvants and was concerned that these vaccines were all being treated as if they were the same.

In addition, she observed that only 13 % of the people in Germany want to take the swine flu jab even though 5 times more people in Germany take the regular flu shot than in Poland, and asked why the Germans are so unwilling to take the jab.

She said there was secrecy surrounding the contents of the vaccines. There is no information about the amount of adjuvants in the vaccinesm, she added.

Furthermore, the family doctor and Health Minister said there is absolutely no information about the side effects of the swine flu jab. *The pharmaceutical companies did not want to take responsibilty for the jab*.

Also, she said that trials for the swine flu jab were being conducted on a relatively small number of healthy people and that these were not adequate for her to recommend the jab. Moreover, Kopacz said that the regular flu was much more common and dangerous than the swine flu - and yet no pandemic had been declared over the seasonal flu. Why is there such a panic about the swine flu virus? She asked. Kopacz said that the Polish people can tell the difference between objective facts and the truth and lies. She noted that all 193 people who allegedly had the swine flu in Poland had survived.

Finally, she called on the people of Poland to show their support for her as she comes under growing pressure from the pushers of the "swine flu" jab to give the people the dangerous and untested jab.

Pandemic vaccines – The legal landscape

N. Engl. J. Med. 2010, 362, 1949–1952;
DOI: 10.1056/NEJMp1000938

Vaccines and vaccination – law feature prominently in pandemic preparedness plans. The recent H1N1 influenza vaccine program provides an important opportunity to assess the complex and perhaps paradoxical effects of vaccine laws during a pandemic.

The vaccine market is fragile, prone to shortages of both supply and demand. These shortages have been attributed to such factors as the ***high costs and low profits*** of vaccine production, the public's failure to appreciate the importance of vaccination (due, ironically, to vaccines' success in reducing the prevalence of once-common diseases), fears about vaccine safety, and tort liability. In order to protect public health, law must address each of these concerns. Resolving one without exacerbating another is always challenging; during a pandemic, it can be especially difficult.

Ever since the 1976 National Swine Flu Vaccination Program, *Congress has addressed these problems by coupling liability protection for vaccine makers with alternative compensation programs for injured patients*. For example, the National Childhood Vaccine Injury Act (NCVIA, see National Childhood Vaccine Injury Act) provides relatively swift, but limited, compensation for persons with well-recognized listed injuries from covered vaccines.

NCVIA also allows other claimants to go before a tribunal of Special Masters of the U.S. Court of Federal Claims, known as the Vaccine Court, to show that a vaccine caused their injury. This court's rulings can be reviewed by the U.S. Court of Appeals for the Federal Circuit. Parties who are dissatisfied with a Vaccine Court ruling also retain a limited right to sue in state court.

Recently, the U.S. Supreme Court agreed to review a case, *Bruesewitz v. Wyeth*, in which the U.S. Court of Appeals for the Third Circuit held that NCVIA bars a state-law design-defect claim brought by a minor after the Vaccine Court found that the whole-cell diphtheria–pertussis–tetanus vaccine did not cause her neurologic injuries. The Supreme Court's decision in *Bruesewitz* should help to clarify which state-law claims survive NCVIA.

When Congress focused on pandemics in 2005, it again combined tort immunity with no-fault compensation. Under the Public Readiness and Emergency Preparedness (PREP) Act (see Public Readiness and Emergency Preparedness Act), manufacturers, distributors, and health care providers administering vaccines and other pandemic countermeasures are granted total immunity (except in cases of willful misconduct) when the secretary of health and human services invokes such immunity while declaring a public health emergency. The PREP Act also authorizes limited no-fault compensation for persons harmed by covered countermeasures, but unlike NCVIA, it does not allow for judicial review or civil litigation. In June 2009, Secretary of Health and Human Services Kathleen Sebelius issued an emergency declaration for H1N1 influenza. The declaration has since been updated and reissued several times.

Ideally, the PREP Act's immunity provisions – in conjunction with Section 564 of the Food, Drug, and Cosmetic Act, which allows the Food and Drug Administration to issue emergency-use authorizations – remove legal obstacles to the rapid production and dissemination of pandemic vaccines.

JLPP
Journal of Law and Public Policy

Joanna B. Apolinsky, Jeffrey A. Van Detta

Rethinking Liability for Vaccine Injury

Cornell Journal of Law and Public Policy, Summer, 2010, 19(3): article 1
https://scholarship.law.cornell.edu/cjlpp/vol19/iss3/1

Conclusion

The problem of vaccine-liability involves clashing interests and polycentric policy decisions. The instrumentalist approach that had placed protecting manufacturers from legal liability as its foremost goal-leading to the NCVIA and more recent FDA-preemption theories-distorts the nature of the issue by shifting the focus away from the relationship of distributing vaccine-injury costs to the larger problem of integrating injury compensation into a coherent national policy of vaccine funding, research, development, distribution, and reporting of complications.

When considered in light of three fundamental principles relevant to developing rules in this area (enterprise regulation, corrective justice, and social compact) and the polycentric nature of dealing with the balancing of those principles in the six classifications of risk into which vaccinerelated injuries can be sorted, the problem is clearly one that requires political policy-making from a holistic perspective. Congress needs to act, and needs to act now, to transcend their previously disjointed and episodic legislative response to a randomly arising assortment of lobbyists and vaccine-related crises. Instead, as the role of the vaccine promises to increase substantially in the genetic engineering world of a rapidly increasing global population and concentration of people in cities, Congress needs to step back and rethink a series of vaccine-related issues in order to assure the integrity of the individual, society, and of the pharmaceutical development and manufacturing industry.

Only by rethinking vaccine-injury liability within this larger context, and legislating to address such questions as part of comprehensive regulation to ensure vaccine accessibility and continued development, can Congress advance the dialogue beyond partisan questions driven by trial lawyers and tort reformists-a myopic focus that threatens, metaphorically, to allow Washington to bum while Congress fiddles.

Vaccines have become a fundamental aspect anchoring the modem human condition at its optimal realization-not a luxury, nor a cause against which social non-conformists can rally to rebel, nor just another profit center or loss leader for pharmaceutical industry shareholders. Holistic vaccine policy must wield the power of Congress to control the pharmaceutical industry's access to the riches awaiting those who gain the favor of FDA-drug approval in order to finance a national program of vaccine research, development, manufacture, distribution, and injury compensation.

JUSTIA U.S. Supreme Court

Bruesewitz v. Wyeth LLC, 562 U.S. 223 (2011)

Supreme Court of the United States; Docket No. 09-152
Granted: March 8, 2010 // Argued: October 12, 2010 // Decided: February 22, 2011
https://supreme.justia.com/cases/federal/us/562/223/

Syllabus
October Term, 2010
Bruesewitz V. Wyeth LLC

Supreme Court of the United States

Bruesewitz et al. *v.* Wyeth LLC, fka Wyeth, INC., et al. Certiorari to the United States Court of Appeals for the third circuit Argued October 12, 2010–Decided, No. 09–152. February 22, 2011

The National Childhood Vaccine Injury Act of 1986 (NCVIA or Act) created a no-fault compensation program to stabilize a vaccine market adversely affected by an increase in vaccine-related tort litigation and to facilitate compensation to claimants who found pursuing legitimate vaccine-inflicted injuries too costly and difficult. The Act provides that a party alleging a vaccine-related injury may file a petition for compensation in the Court of Federal Claims, naming the Health and Human Services Secretary as the respondent; that the court must resolve the case by a specified deadline; and that the claimant can then decide whether to accept the court's judgment or reject it and seek tort relief from the vaccine manufacturer. Awards are paid out of a fund created by an excise tax on each vaccine dose. As a *quid pro quo,* manufacturers enjoy significant tort-liability protections. Most importantly, the Act eliminates manufacturer liability for a vaccine's unavoidable, adverse side effects.

Hannah Bruesewitz's parents filed a vaccine-injury petition in the Court of Federal Claims, claiming that Hannah became disabled after receiving a diphtheria, tetanus, and pertussis (DTP) vaccine manufactured by Lederle Laboratories (now owned by respondent Wyeth). After that court denied their claim, they elected to reject the unfavorable judgment and filed suit in Pennsylvania state court, alleging, *inter alia,* that the defective design of Lederle's DTP vaccine caused Hannah's disabilities, and that Lederle was subject to strict liability and liability for negligent design under Pennsylvania common law. Wyeth removed the suit to the Federal District Court. It granted Wyeth summary judgment, holding that the relevant Pennsylvania law was preempted by 42 U. S. C. §300aa–22(b)(1), which provides that "[n]o vaccine manufacturer shall be liable in a civil action for damages arising from a vaccine-related injury or death associated with the administration of a vaccine after October 1, 1988, if the injury or death resulted from side-effects that were unavoidable even though the vaccine was properly prepared and was accompanied by proper directions and warnings." The Third Circuit affirmed.

Held: The NCVIA preempts all design-defect claims against vaccine manufacturers brought by plaintiffs seeking compensation for injury or death caused by a vaccine's side effects. Pp. 7–19.

(a) Section 300aa–22(b)(1)'s text suggests that a vaccine's design is not open to question in a tort action. If a manufacturer could be held liable for failure to use a different design, the "even though" clause would do no work. A vaccine side effect could alway*s* have been avoidable by use of a different vaccine not containing the harmful element. The language of the provision thus suggests the design is not subject to question in a tort action. What the statute establishes as a complete

defense must be unavoidability (given safe manufacture and warning) with respect to the particular design. This conclusion is supported by the fact that, although products-liability law establishes three grounds for liability—defective manufacture, inadequate directions or warnings, and defective design—the Act mentions only manufacture and warnings. It thus seems that the Act's failure to mention design-defect liability is "by deliberate choice, not inadvertence." *Barnhart* v. *Peabody Coal Co.*, 537 U. S. 149, 168. Pp. 7–8.

(b) Contrary to petitioners' argument, there is no reason to believe that §300aa–22(b)(1)'s term "unavoidable" is a term of art incorporating Restatement (Second) of Torts §402A, Comment *k,* which exempts from strict liability rules "unavoidably unsafe products." "Unavoidable" is hardly a rarely used word, and cases interpreting comment *k* attach special significance only to the term "unavoidably unsafe products," not the word "unavoidable" standing alone. Moreover, reading the phrase "side effects that were unavoidable" to exempt injuries caused by flawed design would require treating "even though" as a coordinating conjunction linking independent ideas when it is a concessive, subordinating conjunction conveying that one clause weakens or qualifies the other. The canon against superfluity does not undermine this Court's interpretation because petitioners' competing interpretation has superfluity problems of its own. Pp. 8–12.

(c) The structure of the NCVIA and of vaccine regulation in general reinforces what §300aa–22(b)(1)'s text suggests. Design defects do not merit a single mention in the Act or in Food and Drug Administration regulations that pervasively regulate the drug manufacturing process. This lack of guidance for design defects, combined with the extensive guidance for the two liability grounds specifically mentioned in the Act, strongly suggests that design defects were not mentioned because they are not a basis for liability. The Act's mandates lead to the same conclusion. It provides for federal agency improvement of vaccine design and for federally prescribed compensation, which are other means for achieving the two beneficial effects of design-defect torts–prompting the development of improved designs, and providing compensation for inflicted injuries. The Act's structural *quid pro quo* also leads to the same conclusion. The vaccine manufacturers fund an informal, efficient compensation program for vaccine injuries in exchange for avoiding costly tort litigation and the occasional disproportionate jury verdict. Taxing their product to fund the compensation program, while leaving their liability for design defect virtually unaltered, would hardly coax them back into the market. Pp. 13–16.

561 F. 3d 233, affirmed.

Scalia, J., delivered the opinion of the Court, in which Roberts, C. J., and Kennedy, Thomas, Breyer, and Alito, JJ., joined. Breyer, J., filed a concurring opinion. Sotomayor, J., filed a dissenting opinion, in which Ginsburg, J., joined. Kagan, J., took no part in the consideration or decision of the case.

TS NEWS

Landmark Lawsuit Challenges Vaccine Manufacturer Protections Under PREP Act

TSNews, 13 March 2025, 9:00 a.m.
https://www.trialsitenews.com/a/landmark-lawsuit-challenges-vaccine-manufacturer-protections-under-prep-act-fc84f9db

A legal firestorm has erupted in Texas as a group of vaccine-injured Americans, led by Dr. Joel Wallskog and represented by Siri & Glimstad, L.L.P., take on the federal government in a lawsuit that could dismantle legal immunities shielding COVID-19 vaccine manufacturers. At the heart of the battle is the Public Readiness and Emergency Preparedness (PREP) Act, which grants sweeping liability protections to pharmaceutical companies in public health emergencies. Plaintiffs argue this framework unlawfully denies them their constitutional rights to due process and access to the courts, leaving them trapped in the labyrinthine Countermeasures Injury Compensation Program (CICP) – a system with a staggering 98% denial rate.

The Case Against Immunity

The lawsuit, Case No. 4:24-cv-00334-P, filed in the U.S. District Court for the Northern District of Texas, contends that the PREP Act effectively blocks individuals injured by COVID-19 vaccines from seeking justice in the judicial system. Instead, they are funneled into the CICP, a bureaucratic black hole with no transparency, legal representation, or right to appeal. The plaintiffs – each with life-altering vaccine injuries – demand an end to this immunity shield, arguing that it violates the 5th and 7th Amendments, which protect the right to due process and a jury trial.

Among them is Dr. Joel Wallskog, an orthopedic surgeon whose career was shattered by transverse myelitis following his Moderna vaccination. Wallskog went on to join Brianne Dressen to form React19 as a non-profit advocacy for individuals injured by COVID-19 vaccines.

Jessica Smith, a young mother, faces financial ruin as she battles severe dysautonomia and tinnitus, while Harvard Professor Elizabeth Thiele, MD, Ph.D., struggles with debilitating shoulder injuries. Perhaps the most gut-wrenching case is 10-year-old T.C., whose permanent blood disorder demands costly treatment – yet his family has waited 18 months without a single response from the CICP.

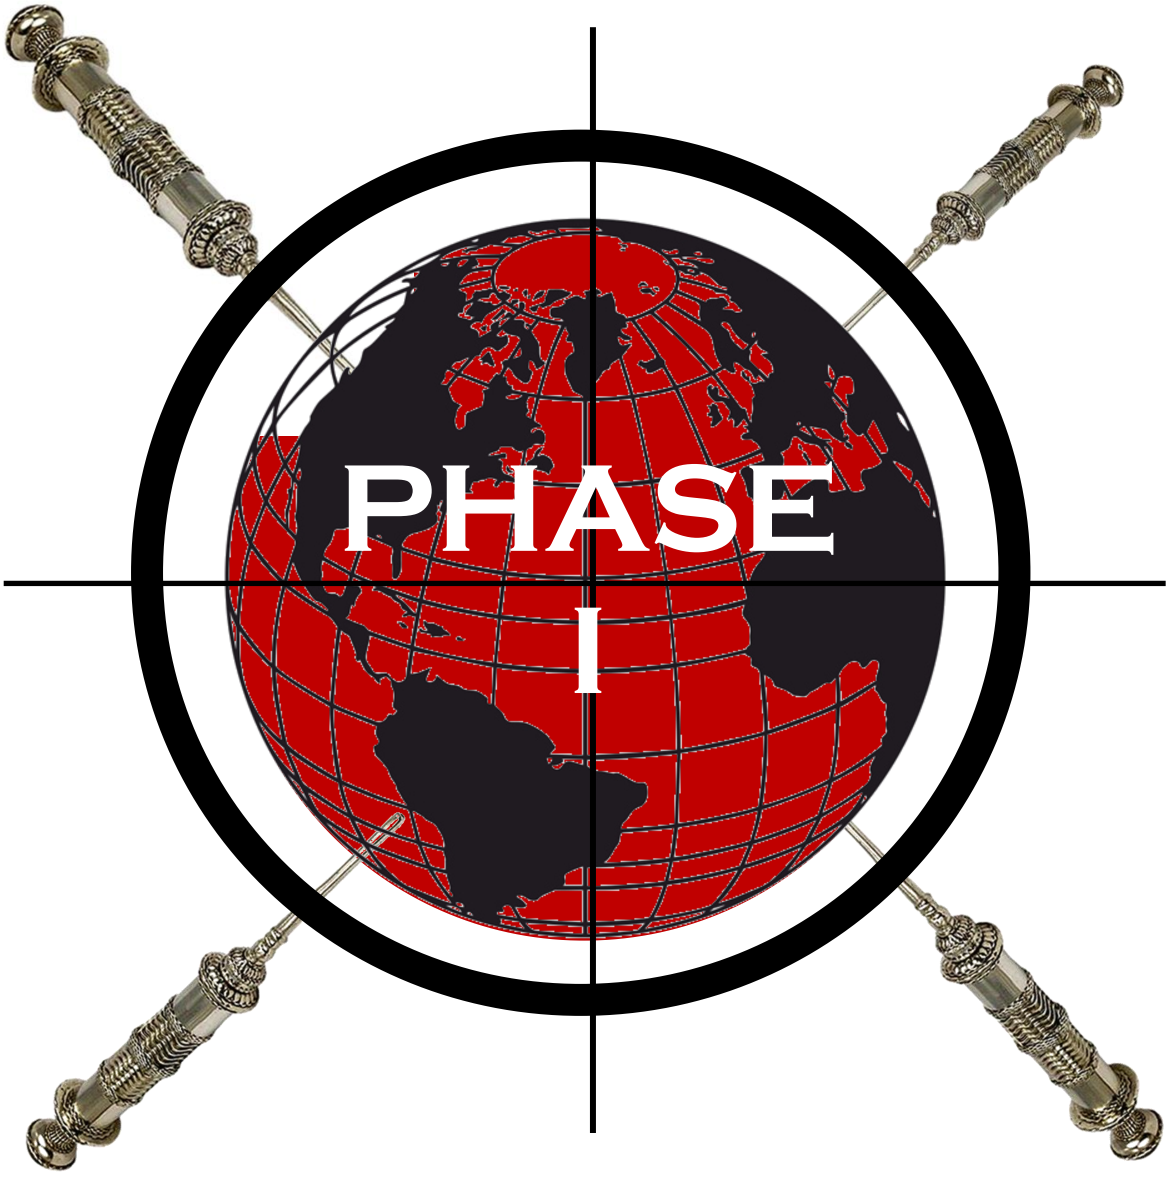
The Legal Battleground--PREP Act Under Fire

The PREP Act, enacted in 2005, was designed to shield vaccine manufacturers from lawsuits during public health emergencies, ensuring the swift development and deployment of critical countermeasures. As *TrialSite* has reported, its creation was largely shaped by the aftermath of 9/11 and the anthrax attacks, which spurred a heightened focus on biodefense. This led to establishing a framework aimed at accelerating medical countermeasures to protect the U.S. homeland. The protection of countermeasure developers was very much integral to the law.

The government argues that without such protections, companies would be reluctant to develop vaccines in crisis situations, potentially costing millions of lives. But critics argue that this blanket immunity represents a serious overreach, stripping individuals of their fundamental rights and leaving the injured with no real recourse.

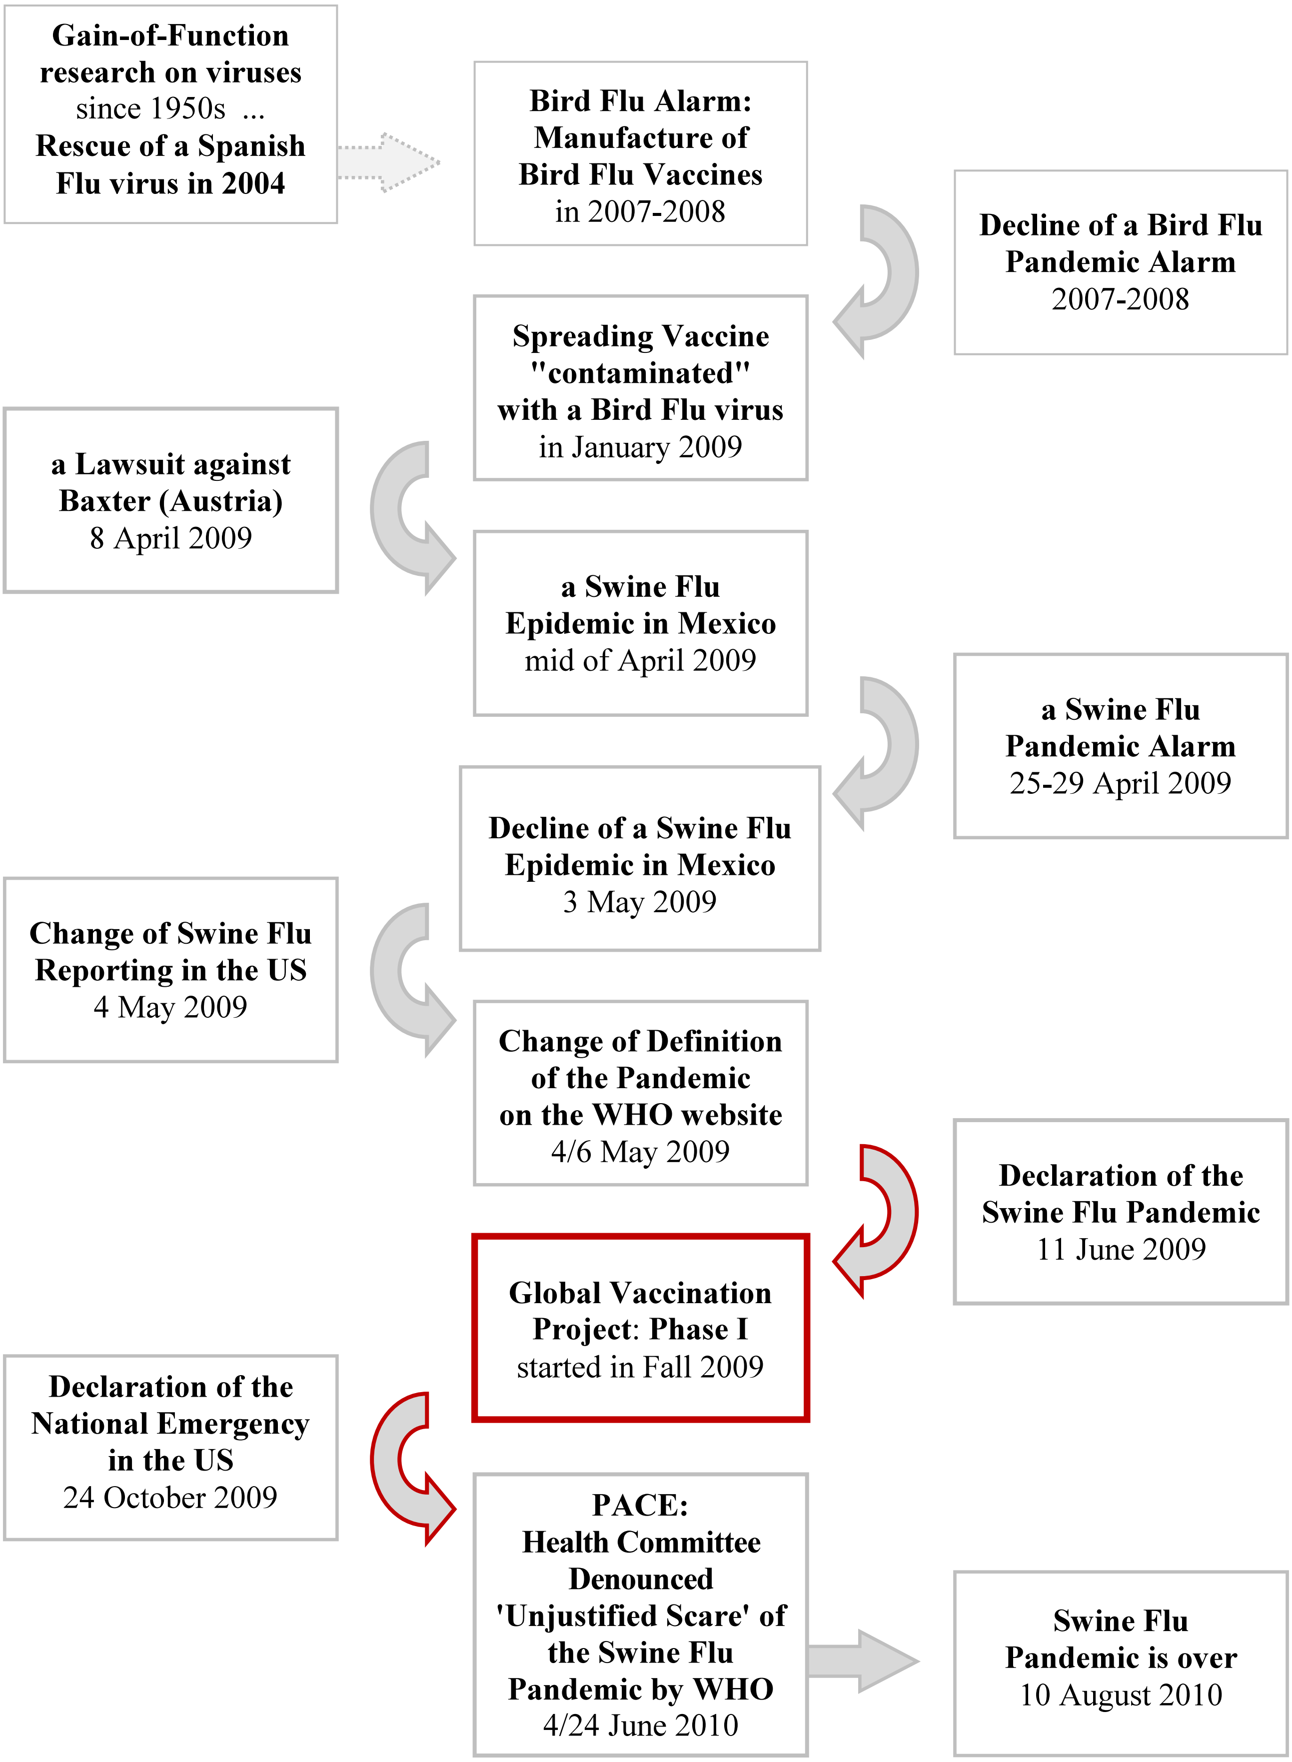
The plaintiffs contend that the CICP fails as an alternative compensation mechanism. Unlike the Vaccine Injury Compensation Program (VICP) – which has paid out billions to vaccine-injured

individuals since 1988 – the CICP operates under a shroud of secrecy, with virtually no public accountability. Only a handful of claims have been approved, and payouts are minimal, leaving victims financially devastated.



A High-Stakes Showdown

This case could set a monumental precedent. If the court sides with the plaintiffs, it could open the floodgates for litigation against vaccine manufacturers, forcing a re-evaluation of the PREP Act's liability shield. Pharmaceutical companies and public health officials warn that such a ruling could stifle future vaccine innovation. But for the plaintiffs, this fight is about fundamental constitutional rights – the right to due process, the right to be heard, and the right to justice.



Will the courts uphold the PREP Act's sweeping protections, or will they rule that the government cannot strip injured individuals of their day in court? As the legal battle unfolds, the stakes couldn't be higher – not just for the plaintiffs but for the future of public health policy in America.

Chapter 6

Global
Vaccination Campaign

Roadmap
of the Swine Flu Pandemic

Dr Margaret Chan
Director-General of the World Health Organization

World now at the start of 2009 influenza pandemic

Geneva, WHO, 11 June 2009
https://www.cidrap.umn.edu/h1n1-2009-pandemic-influenza/who-declares-pandemic-novel-h1n1-virus
https://web.archive.org/web/20090611173204/http://www.who.int/mediacentre/news/statements/2009/h1n1_pandemic_phase6_20090611/en/index.html

Ladies and gentlemen,

In late April, WHO announced the emergence of a novel influenza A virus. This particular H1N1 strain has not circulated previously in humans. The virus is entirely new. The virus is contagious, spreading easily from one person to another, and from one country to another. As of today, nearly 30,000 confirmed cases have been reported in 74 countries. This is only part of the picture. With few exceptions, countries with large numbers of cases are those with good surveillance and testing procedures in place.

Spread in several countries can no longer be traced to clearly-defined chains of human-to-human transmission. Further spread is considered inevitable. I have conferred with leading influenza experts, virologists, and public health officials. In line with procedures set out in the International Health Regulations, I have sought guidance and advice from an Emergency Committee established for this purpose. On the basis of available evidence, and these expert assessments of the evidence, the scientific criteria for an influenza pandemic have been met.

I have therefore decided to raise the level of influenza pandemic alert from phase 5 to phase 6.
The world is now at the start of the 2009 influenza pandemic. We are in the earliest days of the pandemic. The virus is spreading under a close and careful watch.

No previous pandemic has been detected so early or watched so closely, in real-time, right at the very beginning. The world can now reap the benefits of investments, over the last five years, in pandemic preparedness. We have a head start. This places us in a strong position. But it also creates a demand for advice and reassurance in the midst of limited data and considerable scientific uncertainty.

...

We are all in this together, and we will all get through this, together.

Thank you.

Baxter could have pandemic flu vaccine in July

Reuters, 13 June 2009
https://www.reuters.com/article/us-flu-baxter-idUSTRE55B5O620090612

NEW YORK (Reuters) - Baxter International Inc said on Friday that it is in full-scale production of an A/H1N1 flu pandemic vaccine that could be ready for commercial use next month.

The news comes a day after the World Health Organization (WHO) officially declared a pandemic and cautioned governments to prepare for a long-term battle against the new virus.

Baxter said it received an A/H1N1 strain from the U.S. Centers for Disease Control and Prevention in May and has been working to develop a pandemic vaccine for use as early as July.

A number of national public health authorities have agreements with Baxter that allow them to place orders for a vaccine now that a pandemic has been declared by WHO, Baxter said.

Baxter said it would also work with WHO to allocate a portion of the company's commercial vaccine production to address global public health issues deemed most urgent.

The company, which said it has completed testing and evaluation of the virus, is developing the vaccine using cell technology. Traditional flu vaccines are made using chicken eggs and typically take some six months to produce.

Baxter said it believes its Vero cell technology will allow for much more rapid production and delivery of pandemic flu vaccine.

The company plans to submit the A/H1N1 vaccine for approval upon completion of initial manufacturing runs.

A/H1N1 flu strain was first discovered in Mexico and has rapidly spread. There have been 28,774 confirmed cases of the virus in 74 countries with 144 deaths, according to WHO's latest tally of laboratory-confirmed cases. It is believed that tests have turned up only a fraction of the true number of cases of the virus.

Swine Flu Vaccine: Will we Have a Choice?

NVIC, 18 June 2009, 1:26:51 PM
https://web.archive.org/web/20090626043642/http://www.nvic.org/NVIC-Vaccine-News/June-2009/Swine-Flu-Vaccine--Will-We-Have-A-Choice--by-Barba.aspx

The summer will be over before we know it and it will be time for the school year to begin. This fall, many parents are wondering what will happen to their children when they enter the schools. Some public health doctors want to turn schools into vaccination clinics where children will be the first to be injected with experimental swine flu vaccines.[1]

Less Than 50,000 Swine Flu Cases Worldwide

Every day we are being warned by doctors at the World Health Organization and the U.S. Centers for Disease Control to worry a lot about the H1N1 influenza A virus, which was first identified in Mexico in April 2009 and is being called the new swine flu. As of June 15, 2009, the World Health Organization states that 76 countries have reported more than 35,000 cases, including 163 deaths. 108 of those deaths have occurred in Mexico.[2]

We are being told that nearly 18,000 Americans have gotten sick from the new swine flu virus, with about 5 percent being hospitalized and 45 dying.[3] It looks like people, who are in poor health to begin with are at greater risk of having complications and dying from the new swine flu, which has symptoms just like regular influenza.[4,5] This is not surprising because people in poor health are always at greater risk of having complications and dying from infectious disease.

Most Flu-Like Illness Not True Influenza

What a lot of people don't know is that true type A or type B influenza only causes about 20 percent of all flu-like symptoms that people experience during any given flu season.[6] 80 percent of all flu-like illness in a normal flu season is NOT caused by the type A and B strains of influenza contained in annual flu shots. And vaccine acquired immunity is temporary, while immunity gained after recovering from influenza is longer lasting.[7,8]

1968 Flu Pandemic Killed 34,000 Americans

The new type A H1N1 influenza virus public health doctors say is making people sick around the world is an unusual combination of human, bird and pig viruses.[9] Nobody seems to know exactly how this new virus was created and why it suddenly emerged from Mexico in mid-April - or if it will behave like past pandemic influenza viruses that caused 68,000 American deaths in 1957 and killed 34,000 Americans in 1968.[10] (The CDC states that 36,000 Americans die from influenza complications annually, with most of those deaths occurring in the elderly and those in poor health). Influenza pandemics usually start with mild symptoms and progress to more severe symptoms before populations acquire immunity to the virus and it dies out.

Older Americans May Have Antibodies Against Swine Flu

The good news about the new swine flu going around is that there are signs those of us born before 1957, may be naturally protected and at LOWER risk of being infected.[11,12] Why? Because we recovered from influenza caused by similar influenza strains that circulated in past decades and have long lasting antibodies that help us resist infection. So the aging baby boomers have something to be happy about.

Vaccinated Children Don't Have Natural Antibodies

But will health officials allow our children and grandchildren to get those same kind of natural protective antibodies to type A and B influenza, including this new swine flu? It doesn't look like it. First, doctors in America have been insisting for the past few years that every child from six months old to age 18 must get an annual flu shot.[13] Second, there are now calls by U.S. health officials to give American children the first doses of experimental swine flu vaccines in the school setting.[14]

WHO Declares Phase 6 Alert; Public Health Doctors Exercise EUA

This is because the response by doctors at the World Health Organization, who immediately went into high gear within days of identifying the new swine flu virus emerging out of Mexico, was to declare a public health emergency. Now, they have increased the pandemic flu fear alert to Phase 6,[15] which is the equivalent of the U.S. Homeland Security's Code Red warning of an imminent terrorist attack.[16] Doctors at the Centers for Disease Control, who followed the lead of the World Health Organization, have done the same and are exercising unprecedented power that Congress handed over to them after 9-11.

Fast Tracking of Experimental Vaccines With Novel Adjuvants

Whenever the CDC declares a public health emergency, that declaration allows the Food and Drug Administration to permit emergency use authorization for drug companies to fast track creation of experimental drugs and vaccines that do not have to be tested as thoroughly as vaccines that go through the normal FDA licensing process.[17] In this case, Congress responded to the public health emergency declaration by giving a group of drug companies one billion dollars[18] to fast track experimental swine flu vaccines that may include whole live,[19] killed or genetically engineered human and animal influenza viruses, chemicals, and potentially reactive oil based adjuvants that manipulate the immune system to boost the vaccine's potency.[20,21,22]

States Enact Stronger Quarantine & No Free Assembly Laws

In some states, like Massachusetts, public health doctors have persuaded legislators to quickly pass pandemic influenza legislation that will allow state officials to enter the homes and businesses without the approval of occupants; to investigate and quarantine individuals without their consent; to require licensed health care providers to give citizens vaccines and to ban the free assembly of citizens in the state.[23,24]

What Can You Do?

What does this declaration of a public health emergency in the U.S. mean for you and your family? It means that, right now, you need to become educated about vaccination, influenza, vaccine risks, and the public health laws in your state. You need to find out what your rights and options are under new public health laws that may require you and your children to get vaccinated or be quarantined.[25]

Take Action Now

Go to www.NVIC.org and learn more. Register now to attend the Fourth International Public Conference on Vaccination Oct. 2-4, 2009 in Washington, D.C. and help organize in your state to protect your right to informed consent to vaccination. Call and write the state legislators you elected to make public health laws that govern you and your family. Make your voice heard.

Homeland Security, Department of Defense & CDC

As Department of Homeland Security officials are declaring that any disease outbreak is a matter of homeland security;[26,27] as Department of Defense officials are defining public demonstrations as "low level terrorism";[28] as CDC officials make plans to re-route airplanes to designated airports with quarantine centers to screen all passengers for signs of swine flu;[29] and as fast tracked experimental pandemic flu vaccines are being created to be given to American children first, it is time for all of us – whether we are public health officials addressing what we believe is a true public health emergency or whether we are ordinary citizens simply trying to protect our health and the health of our children - to act in rational and responsible ways.

Protect Health Choices

Every pharmaceutical drug, including vaccines, carries a risk and those risks are greater for some than others. In this time of fear, we cannot let that fear take away our freedom to make voluntary health choices, including vaccine choices, so we have the power to make sure that the cure is not more dangerous than the disease.

Китай произвел первую партию вакцины против свиного гриппа

News.ru, 22 июня 2009 г., 15:47
https://www.newsru.com/world/22jun2009/china_5.html

В КНР в понедельник выпущена первая партия вакцины против смертельно опасного вируса A/H1N1 - свиного гриппа. По информации агентства Sina, всего произведено 90 тысяч доз.

Предполагается, что в течение 40-50 дней вакцина пройдет клинические испытания, после чего примерно в сентябре препарат поступит в больницы. До октября будут привиты все представители групп риска, сообщает РИА "Новости".

По мнению экспертов, больше всего подвержены риску заражения гриппом A/H1N1 дети до 7 лет, люди, имеющие хронические заболевания (сердечно-сосудистые и легочные болезни, диабет), а также люди, находящиеся в тревожно-депрессивном состоянии.

Производство вакцины против нового гриппа в Китае началось в начале июня. Изготовлением препарата занимаются 11 фармацевтических предприятий страны. Объем производства планируется довести до 360 миллионов доз в год.

Всего на борьбу с распространением опасной инфекции власти КНР выделили 5 миллиардов юаней (725 миллионов долларов). В Китае зафиксировано уже 737 случаев заражения вирусом гриппа A/H1N1, смертельных случаев пока нет.

Между тем, по последним данным Всемирной организации здравоохранения (ВОЗ), в 95 странах мира официально подтверждены 44287 случаев заболевания людей гриппом A/H1N1. 180 человек скончались.

11 июня ВОЗ впервые более чем за 40 лет официально объявила о введении шестого, максимального уровня угрозы пандемии в связи со стремительным распространением по миру нового вида гриппа. В России официально подтверждены лабораторными анализами три случая заражения A/H1N1.

Россия тоже скоро представит свою вакцину от свиного гриппа

Медики России также готовы в скором времени представить вакцину от нового вируса. Еще в мае они выделили первый в России штамм гриппа A/H1N1, благодаря которому и будет разработана вакцина. На разработку российской вакцины, по оценкам директора Института гриппа РАМН Олега Киселева, уйдет не менее трех месяцев, еще два месяца потребуется на ее испытание и запуск производства. Врачи обещают, что в случае стремительного распространения вируса на территории РФ, препарата хватит всем.

"Что касается вакцины, то здесь особенно чудес никаких нет: на основе традиционного для РФ вируса гриппа A (H1N1) она вырабатывается ежегодно. Сейчас речь идет о том, чтобы привести ее в соответствие с новым высокопатогенным штаммом. Это в состоянии сделать специалисты в России, и мы даже берем обязательства, что постараемся подготовить кандидатную вакцину месяца за три", - сказал Киселев журналистам в понедельник.

По его мнению, Россия столкнется с гриппом A/H1N1 в ноябре этого года, сообщает РИА "Новости". "Вирус гриппа нуждается в сезонной поддержке. Лето - не пора гриппа на территории РФ... В ноябре мы встретим первую реальную волну", - сказал Киселев.

Он напомнил, что к настоящему времени в России подтверждены лишь три случая заболевания гриппом A/H1N1, причем занесенных из других регионов. Также выявлено два случая подозрения на грипп A/H1N1 - в Москве и Петербурге.

Петербургские медики проверяют анализы, взятые у пациента с подозрением на грипп A/H1N1, сообщил Киселев. Он отметил, что в настоящее время петербургские медики продолжают исследовать взятый у пациента биоматериал. "Сейчас материалы расшифровываются. По первым анализам - ситуация сомнительная. Идет повторное исследование", - отметил директор НИИ. Он не смог уточнить состояние здоровья пациента и ему не известно, выписан ли больной из стационара.

Глава НИИ гриппа РАН отметил также, что новые исследования этого вируса, проведенные американским коллегами, "внушают оптимизм". "Он не относится к высокопатогенным", - сказал Киселев. Вместе с тем, по словам главы НИИ, исследователи США подчеркивают, что к группе риска по этому заболеванию относятся те категории граждан, которые имеют серьезные сопутствующие заболевания, например сахарный диабет и сердечно-сосудистые болезни. Этим людям Киселев посоветовал немедленно обращаться к врачу при первых симптомах простуды.

Кроме того, он сообщил, что американские ученые отметили "поразительную чувствительность" к этой болезни людей с избыточны весом. Правда, по его словам, в России и США понятие "избыточный вес" разное, в США к ним относят людей с весом более 120 килограммов. "Я 20 лет занимаюсь этой проблемой и, наверное, первый раз такое объявление в адрес людей с такими проблемам", - сказал Киселев.

Arkansas State Health Department: Mandatory Vaccines Are Constitutional

Prison Planet, 26 June 2009.
https://web.archive.org/web/20100106164203/http://www.prisonplanet.com/arkansas-state-health-department-mandatory-vaccines-are-constitutional.html

A member of the public who was concerned about a mandatory mass vaccination program in light of the swine flu pandemic called the Arkansas State Health Department for advice only to be told that mandatory vaccines were constitutional and could be enforced at gunpoint by the government if necessary.

The editor of the popular blog "Pissed Off Former Democrat" phoned the legal council at the Arkansas State Health Department to seek advice about obtaining waiver forms for a future mass swine flu vaccination program.

One of his main concerns centered around the fact that the company chosen to mass produce the swine flu vaccine, Baxter International, were recently caught in a scandal after it emerged they had sent out vaccines contaminated with the H5N1 avian flu virus to 18 countries from their Austrian branch. It was only by providence that the contamination was found after the batch was first tested on ferrets in the Czech Republic, before being shipped out for injection into humans. The ferrets all died and the shocking discovery was made.

Some Czech newspapers speculated at the time that Baxter was embroiled in a conspiracy to provoke a pandemic from which it would reap billions in profits from producing the vaccine to counter a bird flu outbreak.

As we have previously covered, the last time the government ordered a mass vaccination drive in response to a swine flu outbreak, the program had to be stopped short after the shots caused over 500 cases of Guillain-Barre syndrome, a severe paralyzing nerve disease. 30 people died as a direct result of the vaccinations.

During the phone conversation, the legal council discusses the potential of a future mandatory swine flu vaccination program and states, "That's constitutional, there's no doubt about it….mandatory vaccinations are legal under the Supreme Court….absolutely."

The caller responds, "I'm an American and I have a legal right to make my own decision whether or not someone sticks a needle in me," to which the legal council responds, "That's not true….no."

"As a lawyer you believe that I don't have the right to deny a vaccination," asks the caller," to which the legal council responds, "Absolutely… I don't know why you have a problem with that… mandatory vaccines are constitutional," adding that it doesn't matter about personal or religious objections.

The caller then asks how the mandatory vaccine would be enforced by law, "for example somebody sticking a gun in my face," to which the legal council responds, "you could be held liable."

The legal council at the Arkansas State Health Department cites the 1905 Supreme Court case of Jacobson v Massachusetts to argue that governments can force citizens to take vaccines.

Less than 50 years before, in Dred Scott v. Sandford, the Supreme Court also ruled that black people were slaves - property of their slaveowners with no inherent rights whatsoever.

22 years after Jacobson v Mass., in Buck v Bell, the Supreme Court also ruled that people designated "feeble-minded" by the government could be sterilized.

The fact that the Supreme Court made a ruling over 100 hundred years ago saying the government could inject people by force doesn't make it morally or constitutionally justifiable.

To stick needles in people at gunpoint by government decree is blatantly unconstitutional under any reasonable definition of basic human rights or the freedoms enumerated by the founders in the constitution itself.

American Indians were rounded up and sent to death camps under legal orders, but that didn't make it right or justifiable.

Hitler's mistreatment of Jews, Gypsies, political dissidents, homosexuals and others who resisted government policies imposed during times of "emergency" in Nazi Germany was all perpetrated behind a thin veil of legality, but that didn't make it right either.

As a member at the Prison Planet Forum points out, "Tyrannical evil loves to mask itself in the robes of righteousness, to justify itself with legal documents, to trample the very ideas of what Law and Right mean. Resisting that evil, rising against that tyranny, by saying No More. That is right."

As we previously reported, Time Magazine has been preparing Americans to accept the idea of mandatory vaccinations, reporting on April 28th that a mass vaccination program is being readied to combat swine flu while also urging Americans to "trust that the government is working for the greater good" and to not resist draconian measures.

Canada aims to give H1N1 flu vaccines in October

Reuters, 30 June 2009, 5:43 AM GMT+8
https://www.reuters.com/article/idUSTRE55S6KS/

Ottawa (Reuters) - Canada aims to start immunizing its population against the new H1N1 flu virus in October but has not yet decided who should be a priority for getting the shot, the country's top public health official said on Monday.

"We're hoping that we'll be on track for having the vaccine, start immunizing in late October so that we can complete immunizing before Christmas," Dr. David Butler-Jones, chief public health officer at the Public Health Agency of Canada, told reporters on a conference call.

"There are many things that need to take place between now and then so everything still looks on track, but there's still much work to do," he said.

Drug makers are gearing up to mass produce vaccines against the new virus, also known as swine flu, and governments have reserved millions of doses as the World Health Organization declared a pandemic.

Yet other countries are not sure yet whether even to give the vaccine to anyone and if so, who should get it. The U.S. Centers for Disease Control and Prevention said on Friday it had not yet decided if it will recommend people get the new shots when flu season arrives in North America this fall.

Butler-Jones said Canada would try to learn as much as possible about the virus's behavior before deciding how to proceed with an immunization campaign.

"Right now, we're looking at what's happening in the Southern Hemisphere, we're looking at what's happened in Canada ... and the priorities we'll develop ...," he said.

"We won't get the vaccine all at once and we'll be starting to immunize," he said.

The vaccines for seasonal flu will be ready earlier in the fall and some people may need to get two shots, Butler-Jones said. For the seasonal influenza vaccine, health officials normally prioritize the oldest, the youngest and the sickest. But the majority of those infected with the new virus in Canada are under the age of 20, Butler-Jones said.

So far, 21 Canadians have died from the new H1N1 flu and 496 have been hospitalized with varying degrees of severity, according to data compiled by the public health agency. Most of those with severe symptoms had some form of underlying health condition.

Vaccine safety

Capital News 9, 12 July 2009, 10:19 AM
https://web.archive.org/web/20100201071056/http://capitalnews9.com/capital-region-news-12-content/top_stories/484039/vaccine-safety

It may not be in the mainstream.

"The flu vaccine is loaded with toxins that you just don't want to put in your system."

Information questioning the swine flu vaccine is out there.

"And it's in the majority of flu vaccines and that's mercury."

If you know where to look.

"It's still not proven to be safe yet," said Chris Monahan.

It's counter research that has this father concerned.

"I just don't know what's in it. You can look at the vile and see it, but there's just too many questions," Monahan said.

It's a fear pediatricians say is common. Dr. Michael Pichichero recently published a study he hopes will ease those fears.

"The amount of mercury in these vaccines is safe. And the previous information suggesting that it was not safe is incorrect," Pichichero said.

Rochester Clinical Research has already conducted two pediatric trials of the news H1N1 vaccine.

"This is a process that's been tried and true for years and years," said Dr. Matthew Davis.

While they sped up the normal trial period, Dr. Davis says safety was not compromised.

"The public should have confidence that the vaccine that will be widely administered in October is as safe as any other influenza vaccine that they may have gotten in past years," Davis said.

Davis says no one in the trial has experienced any adverse side effects.

When it comes to the safety of his two kids...

"It's just not the natural way to go," Monahan said.

Monahan still isn't convicted.

"Nobody knows what it's going to do. They say it's going to do this, but is it?" Monahan wondered.

YAHOO! NEWS UK & IRELAND

'All Brits' to be Vaccinated for Swine Flu

Sky News, 12 July 2009, 11:58 am.
https://web.archive.org/web/20090715202501/http://uk.news.yahoo.com/5/20090712/tuk-all-brits-to-be-vaccinated-for-swine-45dbed5.html

The entire population could be vaccinated against swine flu as health chiefs draw up plans to build a nationwide immunity to the disease.

In what would be the biggest vaccination programme of the last 50 years, experts are already formulating a priority list of patients before the bug becomes more virulent.

The fast-tracking comes after the first British patient without underlying health problems succumbed to the disease - the 15th swine flu death in the UK.

Peter Holden, the British Medical Association's lead negotiator on swine flu, told The Sunday Times: "The high risk groups will be done at GPs' surgeries."

He added: "If the virus does (mutate), it can get a lot more nasty, and the idea is to give people immunity.

"But the sheer logistics of dealing with 60 million people can't be underestimated."

On Saturday holidaymakers were advised to check their travel insurance and keep in touch with tour operators as the bug sweeps across the UK.

As school holidays approach, people who contract the virus should consult doctors about whether to stay at home, according to travel association Abta.

Spokeswoman Frances Tuke said the firm had received calls "with regard to insurance".

"Apparently some insurers are placing exemptions on policies. If you need to cancel because of swine flu you need to check your travel insurance policy to ensure it is covered."

Nearly 10,000 Britons have gone down with swine flu after it spread to the UK from Mexico - the third highest case total in the world.

The latest death happened at Basildon and Thurrock University Hospitals NHS Foundation Trust, NHS East of England.

Chief Medical Officer Sir Liam Donaldson has warned that other healthy people were at risk of dying from the disease.

He said: "As with all flu-like viruses, some people are at higher risk than others. Unfortunately, people who are otherwise healthy could also become seriously ill or, sadly, die."

But Sir Liam added: "Fortunately, this particular new virus isn't nearly as severe as it could have been.

"If it had, for example, come out of the bird flu variant it would have been producing much higher levels of mortality."

Brits Tell Goons with needles to stick it where the Sun don't shine

Prison Planet, 12 July 2009.
https://web.archive.org/web/20091126081029/http://www.infowars.com/brits-tell-goons-with-needles-to-stick-it-where-the-sun-dont-shine/

The trial balloon went up today on the UK government's efforts to impose a mass mandatory vaccination program against swine flu, but judging from the response on a major newspaper website, millions of British citizens will tell the goons with needles to stick it where the sun don't shine.

Sky News reports today that, "The entire population could be vaccinated against swine flu as health chiefs draw up plans to build a nationwide immunity to the disease."

According to health authorities, they plan to have 60 million plus UK citizens vaccinated by this time next year, despite the fact that only one healthy person has died from swine flu in Britain.

The resounding response to the government's efforts to prepare everyone to accept the shot is a vehement, "I don't think so!"

Respondents to a London Times article concerning the fact that the vaccine will be rushed through safety procedures in just five days, increasing the chances of it causing deaths and injuries in the thousands, as happened with the 1977 mass vaccination program in the U.S. which killed more people than the actual swine flu virus, overwhelmingly indicated that they would refuse to take the shot.

"Nobody's coming anywhere near me or my family with their experimental mass vaccine/poison programme," wrote one. "We will take our chances of catching their manufactured bird/pig/human virus, that was accidentally on purpose! released onto an unsuspecting public in the first place!"

"Anybody who reads this obviously still has the ability to reason and be guided by their own survival instinct and thus should listen to it. The mass fear mongering is a worldwide, co-ordinated and open conspiracy with massive geo political underpinnings. Don't be fooled, eat properly and exercise," adds another.

"A vaccine that is – effectively – being tested on the population, the prime reasons for such being the economy and easing pressure on the NHS? I'll be another one who passes," comments another.

"Thanks but no thanks. Rushed through tests in 5 days? What about long term effects? Vioxx and Thalidomide had long testing. How safe did they turn out to be? The side effects of Statins that they want everyone to take are worrying. I'll take my chances with cholesterol," writes another.

In fact, nearly every one of the respondents to the article so far clearly states that they will refuse to take the shot.

What will the government do when millions of people refuse to take the vaccine? Will they forcibly inject people at gunpoint as health authorities in the U.S. seem to think is constitutional and the right thing to do?

Would you take a vaccine made by a company that got caught contaminating its product with live avian flu virus?

Would you, as an American citizen, take a vaccine from a government that counts amongst its chief scientific advisors a man who once advocated the mass sterilization of the entire U.S. population through the water supply?

I think the answer is clear, U.S. and UK governments – your goons can stick their needles up their backsides because we are not taking it!

World Health Organization

WHO recommendations on pandemic (H1N1) 2009 vaccines
Pandemic (H1N1) 2009 briefing note 2

Geneva, WHO, 13 July 2009
https://web.archive.org/web/20091030055008/http://www.who.int/csr/disease/swineflu/notes/h1n1_vaccine_20090713/en/index.html

13 July 2009, Geneva – On 7 July 2009, the Strategic Advisory Group of Experts (SAGE) on Immunization held an extraordinary meeting in Geneva to discuss issues and make recommendations related to vaccine for the pandemic (H1N1) 2009.

SAGE reviewed the current pandemic situation, the current status of seasonal vaccine production and potential A(H1N1) vaccine production capacity, and considered potential options for vaccine use.

The experts identified three different objectives that countries could adopt as part of their pandemic vaccination strategy:

- protect the integrity of the health-care system and the country's critical infrastructure;
- reduce morbidity and mortality; and
- reduce transmission of the pandemic virus within communities.

Countries could use a variety of vaccine deployment strategies to reach these objectives but any strategy should reflect the country's epidemiological situation, resources and ability to access vaccine, to implement vaccination campaigns in the targeted groups, and to use other non-vaccine mitigation measures.

Although the severity of the pandemic is currently considered to be moderate with most patients experiencing uncomplicated, self-limited illness, some groups such as pregnant women and persons with asthma and other chronic conditions such as morbid obesity appear to be at increased risk for severe disease and death from infection.

Since the spread of the pandemic virus is considered unstoppable, vaccine will be needed in all countries. SAGE emphasized the importance of striving to achieve equity among countries to access vaccines developed in response to the pandemic (H1N1) 2009.

The following recommendations were provided to the WHO Director-General:

- All countries should immunize their health-care workers as a first priority to protect the essential health infrastructure. As vaccines available initially will not be sufficient, a step-wise approach to vaccinate particular groups may be considered. SAGE suggested the following groups for consideration, noting that countries need to determine their order of priority based on country-specific conditions: pregnant women; those aged above 6 months with one of several chronic medical conditions; healthy young adults of 15 to 49 years of age; healthy children; healthy adults of 50 to 64 years of age; and healthy adults of 65 years of age and above.

- Since new technologies are involved in the production of some pandemic vaccines, which have not yet been extensively evaluated for their safety in certain population groups, it is very important to implement post-marketing surveillance of the highest possible quality. In addition, rapid sharing of the results of immunogenicity and post-marketing safety and effectiveness studies among the international community will be essential for allowing countries to make necessary adjustments to their vaccination policies.

- In view of the anticipated limited vaccine availability at global level and the potential need to protect against "drifted" strains of virus, SAGE recommended that promoting production and use of vaccines such as those that are formulated with oil-in-water adjuvants and live attenuated influenza vaccines was important.

- As most of the production of the seasonal vaccine for the 2009-2010 influenza season in the northern hemisphere is almost complete and is therefore unlikely to affect production of pandemic vaccine, SAGE did not consider that there was a need to recommend a "switch" from seasonal to pandemic vaccine production.

WHO Director-General Dr Margaret Chan endorsed the above recommendations on 11 July 2009, recognizing that they were well adapted to the current pandemic situation. She also noted that the recommendations will need to be changed if and when new evidence become available.

SAGE was established by the WHO Director-General in 1999 as the principal advisory group to WHO for vaccines and immunization. It comprises 15 members who serve in their personal capacity and represent a broad range of disciplines from around the world in the fields such as epidemiology, public health, vaccinology, paediatrics, internal medicine, infectious diseases, immunology, drug regulation, programme management, immunization delivery, and health-care administration.

Additional participants in the SAGE meeting included members of the ad hoc policy advisory working group on influenza A(H1N1) vaccine, chairs of the regional technical advisory groups and external experts. Observers included industry representatives and regulators who did not take part in the recommendation process in order to avoid conflicts of interest.

THE TIMES

Swine flu vaccine rushed through safety checks

Times, 13 July 2009
https://web.archive.org/web/20100106085053/http://www.timesonline.co.uk/tol/news/uk/health/article6694046.ece

A swine flu vaccine will be fast-tracked for use in Britain within five days once it is developed, and 130 million doses are on order.

The Department of Health expects to have enough vaccine this year to give it to half the population. Further supplies will be available if needed. Each person will need two doses of the vaccine, unless one single jab is found to provide high rates of immunity.

The first doses specific to the H1N1 swine flu virus are set to arrive in September and could be given regulatory approval in less than a week.

The move came after the first British patient without underlying health problems died from swine flu, taking the number of swine flu-linked deaths in Britain to 15. Peter Holden, the British Medical Association's lead negotiator on swine flu, said that GPs' surgeries were prepared for one of the biggest winter vaccination campaigns in almost 50 years. He said that, although swine flu was not generally causing serious illness in patients, health officials were eager to start a mass vaccination campaign, starting first on groups that were susceptible to infection or prone to complications.

It is likely that the elderly would be given a seasonal flu jab to guard against other circulating flu strains – as happens every year – as well as the swine flu vaccination. "The high-risk groups will be done at GPs' surgeries. People are still making decisions over this, but we want to get cracking before we get a second wave, which is traditionally far more virulent," Dr Holden said.

It takes several weeks or months to make flu vaccines, which are cultured using chicken eggs. The European Medicines Agency said the fast-tracked approval procedure has involved trials of a "mock-up" vaccine and that the speed would not compromise patient safety. "The vaccines are authorised with a detailed risk management plan," the agency said.

Maggie Fox (ed)

U.S. to spend another $1 billion on flu vaccine

Reuters, 13 July 2009, 7:05 AM GMT+8
https://www.reuters.com/article/idUSN1287171/

Washington, July 12 (Reuters) - The United States will spend another $1 billion on ingredients for an H1N1 vaccine, U.S. Health and Human Services Secretary Kathleen Sebelius said on Sunday.

"There'll be another $1 billion worth of orders placed to get the bulk ingredients for an H1N1 vaccination. Congress has agreed with the president that this is the number one priority, keeping Americans safe and secure," Sebelius said on CNN.

Sebelius has said plans were on track for a mid-October vaccination program, although it was not certain Americans would be offered the vaccine for the so-called swine flu.

"We are aggressively working on, first of all, testing the virus strains to get a vaccination ready. It needs to be safe so testing and clinical trials will start this month. We'll know a lot more by the end of the summer and it needs to be effective," she said.

The World Health Organization may issue guidance as soon as Monday on whether an H1N1 swine flu vaccine will be offered alongside the seasonal flu vaccine.

Vaccine makers Sanofi-Aventis [SASY.PA], Novartis [NOVN.VX], Baxter [BAX.N], GlaxoSmithKline [GSK.L], Solvay [SOLB.BR] and AstraZeneca's [AZN.L] MedImmune subsidiary have finished making seasonal flu vaccines for this year.

The U.S. Food and Drug Administration has scheduled a July 23 advisory panel meeting to discuss clinical trials of the vaccines against the H1N1 influenza virus and the U.S. Advisory Committee on Immunization Practice wills meet July 29.

"FDA is working with the scientists at NIH (National Institutes of Health) to make sure that we have a safe and effective strain and then we're getting ready to make sure that we have a vaccination program," Sebelius said.

Health experts estimate at least 1 million people have been infected with H1N1 in the United States, and the U.S. Centers for Disease Control and Prevention has confirmed 211 deaths. It often takes weeks or months to collect data on flu deaths.

About 36,000 people die each year from the seasonal flu in the United States alone, and 250,000 to 500,000 die globally.

Los Angeles Times

Karen Kaplan

Booster Shots: What are the odds that H1N1 will kill you?

Los Angeles Times, 14 July 2009, 4:01 PM PT
https://www.latimes.com/archives/blogs/booster-shots/story/2009-07-14/what-are-the-odds-that-h1n1-will-kill-you

It's the one thing everyone really wants to know about the H1N1 pandemic flu: How deadly is it?

By adding up the number of confirmed deaths (429, according to the latest World Health Organization figures) and dividing it by the number of confirmed cases (the WHO says it's 94,512), the simple answer is that the fatality rate is just below 0.5%. That's in line with a bad year for the seasonal flu. But is it accurate?

Not necessarily, according to a group of experts from the Medical Research Council Centre for Outbreak Analysis and Modelling at Imperial College London. In a paper just published online by the British Medical Journal, they describe the reasons why that easy estimate could miss the mark.

For instance, once somebody comes down with the flu, it takes several days or weeks to either die or recover. At any point in time, the number of people known to have become infected is always bigger than the number of people for whom outcomes are known. That means the calculated fatality rate will be too low, and it will grow as the outbreak progresses.

This is exactly what happened in 2003, when severe acute respiratory syndrome spread through Asia, Europe and North America. As the fatality rate rose, people feared the virus had mutated into a deadlier form. If the numbers show H1N1 becoming more lethal when the traditional flu season arrives in the fall, how will public health officials know whether the virus is actually more dangerous? Epidemiologists should take into account the lag time between the onset of flu symptoms and the outcome of infection, the researchers write.

On the other hand, the fact that people with severe symptoms are more likely to interact with the medical system means the calculated fatality rate probably overstates the lethality of the outbreak. "If we take mild unreported cases into account, the true case fatality ratios could therefore be considerably lower and comparable to that for seasonal influenza," the researchers write.

To overcome this source of bias, they suggest close monitoring of at least 1,100 patients from the initial stage of infection to get a full picture of the proportion that requires hospitalization – and the proportion of hospitalized patients that succumbs.

Getting an accurate assessment of H1N1's fatality rate will be crucial in determining the need for school closures and other measures aimed at preventing the spread of the virus, the researchers said.

ZEIT ONLINE

Bundesländer einigen sich auf Impfstrategie

Zeit.de, 15 July 2009, 09:19 Uhr
https://web.archive.org/web/20100104074608/http://www.zeit.de/online/2009/29/schweinegrippe-bundeslaender-impfstrategie

Die deutschen Gesundheitsminister rüsten die Länder zur Abwehr des neuartigen H1N1-Virus. 50 Millionen Impfstoff-Dosen sollen die Bevölkerung schützen

50 Millionen Impfdosen sollen ein Drittel der Bevölkerung in Deutschland gegen das Amerika-Virus immunisieren

Der hessische Gesundheitsministers Jürgen Banzer (CDU) sagte am Dienstag, er habe sich mit seinen Länderkollegen darauf geeinigt, Impfstoff für rund 30 Prozent der Bevölkerung bereitzustellen. Das entspricht 25 Millionen Menschen in Deutschland.

Es solle aber mit Pharmaherstellern verhandelt werden, um zusätzlichen Impfstoff für weiteren Bedarf zu erhalten. Die als Schweinegrippe bekannt gewordene Amerikanische Grippe verläuft allerdings meistens recht milde, wenn sich Menschen mit ihr angesteckt haben. Zudem kann sie in der Regel mit antiviralen Medikamenten behandelt werden.

Das Thüringer Gesundheitsministerium teilte mit, es habe noch keine endgültige Kaufentscheidung gegeben. Im Gespräch seien 50 Millionen Impfstoff-Dosen, sagte Ministeriumssprecher Thomas Schulz. Da zwei Impfungen zum kompletten Schutz nötig sind, reichen diese für 25 Millionen Menschen. "Die Bundesländer werden in den kommenden Wochen gemeinsam Impfstoff bestellen und sich auch darüber verständigen, welche Personengruppen geimpft werden sollen", sagte Schulz und bestätigte damit einen Bericht des Radiosenders Antenne Thüringen.

In den kommenden Tagen werde zudem der Bund eine Verordnung erlassen, welche die gesetzlichen Krankenkassen dazu verpflichte, die Kosten für die Impfung zu übernehmen. Im Anschluss soll über den Bedarf und die Verteilung der Vakzine verhandelt werden.

Grundlage hierfür sei eine zu Wochenbeginn veröffentlichte Empfehlung der Weltgesundheitsorganisation (WHO), sagte Schulz. Demnach sollen zuerst das Gesundheitspersonal, dann ältere Menschen und danach chronisch Kranke geimpft werden. Der Impfstoff wird laut Schulz nach klinischen Tests voraussichtlich zu Beginn der Grippesaison im Herbst bereitstehen.

Dem SPD-Gesundheitsexperten Karl Lauterbach zufolge besitzt die Krankheit das Potenzial, sich rasend schnell auszubreiten, weil das menschliche Immunsystem ihr bislang nicht viel entgegenzusetzen habe. "Dagegen müssen wir gewappnet sein", sagte er dem Tagesspiegel.

Nach jüngsten Zahlen der EU-Seuchenbehörde ECDC sind weltweit bislang mehr als 110.000 Menschen an der Amerikagrippe erkrankt. Es gibt jedoch eine hohe Dunkelziffer. 580 der Patienten sind gestorben. In Deutschland sind bislang 763 Infektionen bestätigt worden.

CTV NEWS

Fight for swine flu vaccine could get ugly

CTV News // The Associated Press, 17 July 2009, 9:13 AM EDT
https://www.ctvnews.ca/fight-for-swine-flu-vaccine-could-get-ugly-1.417429?cache=ypdchpshbgmanqg%3FclipId%3D89563

London – An ugly scramble is brewing over the swine flu vaccine – and when it becomes available, Britain, the United States and other nations could find that the contracts they signed with pharmaceutical companies are easily broken.

Experts warn that during a global epidemic, which the world is in now, governments may be under tremendous pressure to protect their own citizens first before allowing companies to ship doses of vaccine out of the country.

That does not bode well for many nations, including the United States, which makes only 20 percent of the regular flu vaccines it uses, or Britain, where all of its flu vaccines are produced abroad.

"This isn't rocket science," said Michael Osterholm, director of the Center for Infectious Diseases Research and Policy at the University of Minnesota. "If there is severe disease, countries will want to hang onto the vaccine for their own citizens."

Experts say politicians would not be able to withstand the pressure. "The consequences of shipping vaccine to another country when your own people don't have it would be devastating," added David Fedson, a retired vaccine industry executive.

About 70 percent of the world's existing flu vaccines are made in Europe, and only a handful of countries are self-sufficient in vaccines. The U.S. has limited flu vaccine facilities, and because factories can't be built overnight, there is no quick fix to boost vaccine supplies.

Earlier this week, the U.S. Department of Health and Human Services announced it was spending $884 million to buy extra supplies of two key ingredients for a swine flu vaccine. The U.S. has contracts to get swine flu vaccines from Sanofi Pasteur, MedImmune, GlaxoSmithKline and Novartis. Sanofi Pasteur and MedImmune both have vaccine plants in the U.S., while GlaxoSmithKline and Novartis have plants in Europe.

Even if the U.S. held onto all the swine flu vaccine produced domestically, it would still not be enough for all Americans.

About 80 million Americans are vaccinated against the seasonal flu every year. In 2004, when problems with the U.S.' flu vaccine supply at a British factory hit, there were less than 54 million shots available. Flu vaccines were saved for those in high-risk groups like the elderly and pregnant women, and officials asked other people to simply forgo their usual flu shot.

If there are limited swine flu shots during a pandemic that turns more serious, experts are not sure people will be as willing to skip getting a vaccine.

Last week, the World Health Organization reported nearly 95,000 cases of swine flu, including 429 deaths worldwide. If swine flu turns deadlier in the winter, the main flu season in the Northern Hemisphere, countries will likely be clamoring for any available vaccines.

"Pandemic vaccine will be a valuable and scarce resource, like oil or food during a famine," said David Fidler, a professor of law at Indiana University who has consulted for WHO. "We've seen how countries behave in those situations, and it's not encouraging."

Britain claims it will start vaccinating people in August, Italy says it will begin by the end of the year, and many other countries have similar strategies. Those mass vaccination plans could be derailed by problems making the vaccine and by other countries' refusal to ship it abroad.

If the virus remains mild, this could all be moot. Experts estimate swine flu to be about as dangerous as seasonal flu, and there usually isn't a high demand for those vaccines. Still, regular flu kills up to 500,000 people a year.

In past pandemics, or global epidemics, vaccines were never exported before the country that produced them got enough for its own population first.

Unlike the last two pandemics in 1957 and 1968, however, many more countries this time around have struck deals with companies which they say guarantee them first access to vaccine. Yet in a global health emergency, those contracts may ultimately be meaningless.

Countries with flu vaccine plants might decide to seize all vaccines and ban their export, thus breaking the pharmaceutical contracts promising other countries vaccine supplies. These private contracts are not binding international law between two countries, according to Fidler.

He said most vaccine contracts include a clause allowing them to be broken under extraordinary circumstances, such as a health emergency. That would leave the countries who had brokered such deals not only without vaccine, but without legal recourse. – "There's nothing in international law that helps you resolve this, it's just a political nightmare happening in the midst of an epidemiological nightmare," Fidler said.

Britain has ordered 60 million doses, enough to cover its entire population. But those doses are being manufactured by GlaxoSmithKline PLC and Baxter International Inc., whose production plants are in Germany, Austria and the Czech Republic. Neither Britain's department of health or the vaccine manufacturers would comment on delivery plans.

On Thursday, Britain's chief medical officer estimated that as many as 75,000 Britons could eventually be killed by the swine flu pandemic, if 1 in 3 people are infected.

Osterholm said about 80 percent of the United States' pandemic vaccine supply will be coming from abroad and he is very concerned about when it might arrive. Timing could be everything to avoid a vaccine spat. – "It's easy to move vaccine around if the disease is relatively mild. But if it is more severe, countries may not be willing to let it go," he said.

So far, swine flu remains a relatively mild disease, and most people don't need medical treatment to get better. But experts fear the virus could mutate into a more dangerous form. And during the flu season, when the virus spreads more easily, more people will probably fall sick and die.

Public health officials are aware that so-called "vaccine wars" might break out if the swine flu outbreak worsens, but are loathe to even discuss the topic.

The European Centre for Disease Prevention and Control, an agency of the European Union, said it had no mandate to advise countries in such circumstances. WHO said it was not aware of any nations planning to block the shipment of vaccines and said it would work to ensure all countries get enough doses to protect their health workers.

Questions also remain about when a swine flu vaccine will even be available, as WHO reported this week that a fully licensed vaccine might not be ready until the end of the year.

With little or no safety data about a swine flu vaccine, governments that are planning to roll out mass campaigns are taking a gamble, since any rare side effects won't show up until millions of people start getting the shots.

Experts say government promises about when vaccines will arrive should be taken with a huge grain of salt. – "Many pieces of the puzzle are missing," Osterholm said. "Anyone who pretends to have a well-defined schedule of vaccine delivery is obviously very poorly informed."

Vaccine for swine flu may stir global fight
Countries may not be willing to share

Telegram & Gazette // The Associated Press, 17 July 2009, 12:34 am ET.
https://www.telegram.com/story/news/local/north/2009/07/17/vaccine-for-swine-flu-may/51944413007/

Researchers work Thursday in the P4 European High Level Security Laboratory in Lyon, France. The lab is preparing to receive the new swine flu influenza virus.

An ugly scramble is brewing over the swine flu vaccine – and when it becomes available, Britain, the United States and other nations could find that the contracts they signed with pharmaceutical companies are easily broken.

Experts warn that during a global epidemic, which the world is in now, governments may be under tremendous pressure to protect their own citizens first before allowing companies to ship doses of vaccine out of the country.

That does not bode well for many nations, including the United States, which makes only 20 percent of the regular flu vaccines it uses, or Britain, where all of its flu vaccines are produced abroad.

"This isn't rocket science," said Michael Osterholm, director of the Center for Infectious Diseases Research and Policy at the University of Minnesota. "If there is severe disease, countries will want to hang onto the vaccine for their own citizens."

Experts say politicians would not be able to withstand the pressure.

"The consequences of shipping vaccine to another country when your own people don't have it would be devastating," added David Fedson, a retired vaccine industry executive.

About 70 percent of the world's existing flu vaccines are made in Europe, and only a handful of countries are self-sufficient in vaccines. The U.S. has limited flu vaccine facilities, and because factories can't be built overnight, there is no quick fix to boost vaccine supplies.

Earlier this week, the U.S. Department of Health and Human Services announced it was spending $884 million to buy extra supplies of two key ingredients for a swine flu vaccine. The U.S. has contracts to get swine flu vaccines from Sanofi Pasteur, MedImmune, GlaxoSmithKline and Novartis. Sanofi Pasteur and MedImmune both have vaccine plants in the U.S., while GlaxoSmithKline and Novartis have plants in Europe.

Even if the U.S. held onto all the swine flu vaccine produced domestically, it would still not be enough for all Americans.

About 80 million Americans are vaccinated against the seasonal flu every year. In 2004, when problems with the U.S.' flu vaccine supply at a British factory hit, there were less than 54 million shots available. Flu vaccines were saved for those in high-risk groups like the elderly and pregnant women, and officials asked other people to simply forgo their usual flu shot.

If there are limited swine flu shots during a pandemic that turns more serious, experts are not sure people will be as willing to skip getting a vaccine.

Last week, the World Health Organization reported nearly 95,000 cases of swine flu, including 429 deaths worldwide. If swine flu turns deadlier in the winter, the main flu season in the Northern Hemisphere, countries will likely be clamoring for any available vaccines.

"Pandemic vaccine will be a valuable and scarce resource, like oil or food during a famine," said David Fidler, a professor of law at Indiana University who has consulted for WHO. "We've seen how countries behave in those situations, and it's not encouraging."

Swine Flu Vaccine: When?

CBS News, 21 July 2009, 10:00 AM EDT
https://www.cbsnews.com/news/swine-flu-vaccine-when/

Pandemic swine flu doesn't worry most Americans. But that's likely to change very quickly.

Most U.S. schools will open before the fall of 2009. That's when experts warn the second wave of the pandemic may start sweeping the U.S. If that happens the U.S. – as well as the rest of the world – needs to be prepared for the worst. A pandemic that sickens millions could close schools and businesses, halt travel and overwhelm health care facilities.

"A pandemic is much more than a health event," said Bruce Gellin, MD, MPH, director of the National Vaccine Program Office and deputy assistant secretary of the Health and Human Services Department (HHS) to coordinate U.S. vaccination efforts. "Given the way a pandemic could play out, it has consequences across government and across society."

The best defense: A vaccine to protect people from swine flu – before the pandemic peaks.

Will there be a vaccine? Perhaps not that soon. The clock is ticking away the short amount of time before federal officials, including President Barack Obama, have to make hard choices about whether – and how fast – to get swine flu shots to everyone who wants one. Or at least to those who most need one.

One choice is already made: The U.S. government has spent $1.15 billion to buy enough vaccine to immunize the entire U.S. population against the new flu. If the government makes the decision to go ahead with a full-scale vaccination program, it would be the largest, fastest vaccination program in world history.

So what will happen and when? Here's WebMD's timeline, based on meetings and interviews with a number of flu experts. Warning: Flu viruses – and flu vaccine production – are notoriously unpredictable. Many things can change, even by the earliest points of this timeline.

July: Making and Testing the Swine Flu Vaccine

Pandemic swine flu vaccine is already rolling off the production lines of the five different vaccine makers supplying the U.S: 46% will come from Novartis, 26% will come from Sanofi Pasteur, 19% will come from CSL, 6% will come from MedImmune, and 3% will come from GlaxoSmithKline.

By mid-July, clinical tests of the vaccines sponsored by the National Institute of Allergies and Infectious Diseases will begin at the eight Vaccine and Treatment Evaluation Units at Baylor College of Medicine, Houston; Children's Hospital Medical Center, Cincinnati; Emory University, Atlanta; Group Health Cooperative, Seattle; Saint Louis University; University of Iowa, Iowa City; University of Maryland, Baltimore; and Vanderbilt University, Nashville, Tenn.

The five vaccine manufacturers will also start separate clinical tests in the U.S., Australia and Europe. These tests will begin in July and August.

On July 29, the CDC's vaccine advisory committee will vote on who should be first in line to get the vaccine. Current indications suggest that children 0 to 4-years-old will be at the top of the list,

followed by school-age children. Children with asthma and pregnant women are also likely high-priority groups, as are critical emergency-response workers.

Preparing the Country for the Swine Flu Vaccine

Beginning with the July 9 Flu Summit, federal health officials stepped up work with state and local officials to lay the groundwork for a massive immunization effort. HHS Secretary Kathleen Sebelius has pledged $7.5 billion in preparedness funds and $350 million in direct grants to states and territories.

August: Administer Vaccine Now or Later?

By mid- to late-August, seasonal flu vaccine – the normal, three-in-one vaccine against seasonal flu – will start arriving. The CDC will recommend people get their flu shots or flu sniffs earlier than usual this year, to make way for possible pandemic flu vaccination. If there seems to be a huge increase in pandemic flu cases, officials will be tempted to trigger vaccine delivery before safety and efficacy studies are completed.

Would that be safe? The pandemic swine flu bug is a type A H1N1 virus. One of the seasonal flu bugs is also a type A H1N1 flu bug. Seasonal vaccine doesn't protect against the new swine flu bug, but there's a long history of safety and efficacy for flu vaccines made of H1N1 antigens, notes flu expert John Treanor, MD, chief of infectious diseases at the University of Rochester, New York.

"You might be sitting at the end of August faced with the decision to do this," Treanor said. "If we wait, we can't do vaccination until November. If the pandemic flu follows the seasonal-flu pattern with the bulk of activity in January through March, fine. But if we see this second wave coming in September, we might be faced with the decision to do vaccinations without clinical data."

An HHS advisory committee on July 17 strongly recommended that Sebelius give the green light to vaccine production by Aug. 15 -- before safety and dosing tests are finished. That would mean 60 to 80 million vaccine doses could be ready by Sept. 15.

The speed at which pandemic flu vaccine gets to people varies, depending if it is given the traditional way or with something called an adjuvant.

A vaccine includes a piece of virus that evokes a flu-specific immune response. It's called a flu antigen. An adjuvant boosts immune responses to the vaccine and could make the antigen supply go four times as far, allowing the U.S. to share some of its vaccine with the rest of the world. Adjuvant may also elicit broader immune responses, which would be very important if the swine flu virus's genetic code "drifts" a bit before the next pandemic wave.

Vaccinating all Americans would be an effort of historic proportions.

"This would be the largest vaccine drop that has ever happened in the world," says Robin Robinson, PhD. Robinson is the director of the Biomedical Advanced Research and Development Authority (BARDA), the HHS authority that makes sure the nation has the biomedical supplies it needs for emergencies.

"The most we've ever done for seasonal flu vaccine is about 120 million doses in 75 days," he tells WebMD. "At this point, with an antigen-alone pandemic vaccine, we would see about 160 million doses in 30 days. If we go with adjuvant it could be over 300 million in 30 days – and more coming back behind it."

Making Sure the Vaccine Is Safe

The most important question about a pandemic flu vaccine *is whether it will be safe*. Unfortunately, like nearly everything about flu bugs, *safety can't be guaranteed 100 percent.*

What's reassuring is that there's been no safety issue with previous H1N1 flu vaccines. We take them every year. There are rare adverse events, but the benefit of vaccination far outweighs this small risk.

Safety tests will be performed on the new vaccines, but there won't be a lot of time to see what happens in the long term. If the vaccines seem relatively safe – that is, if they don't seem harmful in the first weeks after they're administered – they'll be rolled out on a massive scale. That means relatively rare side effects will be seen only after millions of people are vaccinated.

The last time the nation faced something called swine flu was in 1976 when a flu of swine origin struck an army base, triggering fears of a pandemic. A vaccine was rushed into production. Manufacturers demanded that the government indemnify them against possible injury claims, making the public wary before vaccination even began.

It's still not clear why a rare but serious neurological disorder called Guillain-Barre syndrome hit those vaccinated in 1976 at a higher-than-expected rate. But after some 44 million Americans received the vaccine, safety fears scuttled the vaccination program – and gave "swine flu vaccine" the bad name that still lingers in the American psyche.

How the public perceives the safety of the vaccine will depend on how severe the flu pandemic turns out to be, flu expert Andrew Pavia, MD, said at a June meeting at the Institute of Medicine.

"If this were a 1918-like pandemic, we could tolerate a fair degree of risk," Pavia said. "But for this virus, our sensitivity to risk is going to be much more difficult to calibrate."

September: One Dose or Two?

By mid-September, results from clinical studies will show the best dose for pandemic swine flu vaccine, how many doses are needed for which populations, and whether the vaccine appears safe in different populations.

If the decision was made in August to start packaging vaccine doses, vaccine will become available around Sept. 15. Early results from clinical trials will guide the decision whether to start vaccinating people. But that decision will have to be made before officials have all the information they'd like to have.

A huge question is whether it will take two doses of vaccine to immunize against pandemic flu. It's possible that because this is a new flu, everyone will be like a small child. Children who've never had a flu shot need two flu vaccinations, weeks apart, to be immunized.

But it might take only one shot. Or maybe some people could get by with one shot – perhaps those who have had repeated seasonal flu shots, those who have been infected with seasonal H1N1 flu, or those born before 1957 when a different H1N1 flu circulated.

Who Will Want the Swine Flu Vaccine?

A decision will be made whether to deploy pandemic swine flu vaccine for some or all U.S. residents. If that happens, the CDC will begin an intensive campaign to persuade people at high risk of flu complications to get vaccinated. The program will have to address issues of vaccine safety in a straightforward manner. "Public trust is crucial; we risk it at our peril. If we risk public trust with bad vaccination decisions, it will take us years to recover," Pavia warns.

"You are going to have less data than you want to make a decision on the go or no-go, but you are going to have to make it on the best available data at the time," says Gellin. "The middle of September is where all this stuff theoretically converges. That is the point where at least we think we will have preliminary data to see how the vaccine is performing and say where are we with this epidemic and what is the situation."

October Through December

If a vaccine has not already been rushed into use, officials will make final preparations for vaccination programs in early October. This will include a priority list of who gets the vaccine first.

By late November, the first clinical studies of pandemic swine flu vaccine will be completed. If results differ from preliminary findings, vaccination programs will be adjusted.

Early December

Even if unexpected events delay a vaccination program, most experts think a vaccine will be ready by the end of December. That means huge numbers of Americans will be offered the vaccine before flu season hits its usual peak in January or February. Even if there's already been a second pandemic wave, this will blunt new waves of pandemic illness.

But will Americans accept a vaccine that arrives after the pandemic peaked? Will safety concerns wreck the expensive program? Even the best laid plans often go awry.

MARYLAND
THE DAILY RECORD

UM will conduct early Swine Flu vaccine study

The Daily Record, 22 July 2009
https://thedailyrecord.com/2009/07/22/um-will-conduct-early-swine-flu-vaccine-study/

The University of Maryland is among eight centers chosen to conduct one of the first studies on an experimental vaccine that would prevent the spread of the swine flu, officials said Wednesday.

The country is in a race against time to produce a vaccine for the public at the start of the flu season, when those in public health expect the number of people infected with the new strain of the flu to grow rapidly.

The University of Maryland School of Medicine’s Center for Vaccine Development will start recruiting as many as 1,000 healthy adults and children to test the safety of the vaccine and study its ability to stimulate immune responses to the swine flu, known as the H1N1 virus.

The study will begin in August, as soon as the manufacturer is able to provide the university with enough of the vaccine, said Karen L. Kotloff, professor of pediatrics and a researcher at the Center for Vaccine Development. The estimated start date is August 10.

"This is such a time crunch … every week we have an update on when the manufacturer will get the vaccine to us,” Kotloff said. "This is just the latest.”

Maryland and the seven other federally -funded Vaccine and Treatment Evaluation Units will do their research under the National Institute of Allergy and Infectious Disease, a division of the National Institutes of Health. Maryland will be the lead investigator to test the vaccine produced by Sanofi Pasteur, the vaccines division of Sanofi-aventis Group, while another institution will lead the investigation on the vaccine developed by CSL Biotherapies.

CSL, an Australian firm, began the world’s first human trial of the company’s vaccine Wednesday in Australia.

The swine flu has caused the deaths of three people in Maryland and 263 people in the United States since the outbreak began this spring in Mexico, according to the Centers for Disease Control.

The World Health Organization has declared the H1N1 virus a pandemic because it has continued to spread. The swine flu has killed 700 people worldwide.

Maryland has had 766 confirmed cases of the swine flu, said John M. Colmers, secretary of Health and Mental Hygiene. Colmers said he suspects that number is low because in most cases the flu is mild and many do not seek treatment.

Public health officials are keeping an eye on the Southern Hemisphere to see how the flu progresses during that part of the world’s winter season, Colmers said. He called this summer "the summer of the flu” because cases have continued to pop up, even though the flu is usually dormant in the summer months.

Researchers at Maryland said they expect the vaccine to be as safe as traditional flu vaccines.

"Seasonal flu vaccines have an enormous record,” Kotloff said. "In reality, this is a seasonal flu and there is no reason to think that this vaccine will behave any differently.”

Participants in the trial will receive two doses of vaccine in three-week intervals, and the centers will compare reactions following each dose. Two strengths of the vaccine will be tested to determine which level of vaccine will produce a response that will best protect people from the flu.

U.S. researchers will first test a group of healthy adults and elderly volunteers and then move on to children if the vaccines are well tolerated by the adults. As many as 200 adults, 200 seniors and 600 children may be enrolled in the trials.

In Maryland, testing will take place in Baltimore at the University of Maryland Medical Center and in Frederick and Annapolis.

Maryland's researchers also will participate in future studies of the vaccine that will be led by other members of the Vaccine and Treatment Evaluation Units, which will examine how the vaccine works in combination with the seasonal flu vaccine.

CBSNEWS

Volunteers Needed for H1N1 Flu Vaccine

CBS News, 22 July 2009, 3:46 PM EDT
https://www.cbsnews.com/news/volunteers-needed-for-h1n1-flu-vaccine/

The U.S. government called Wednesday for several thousand volunteers to start rolling up their sleeves for the first H1N1 (swine) flu shots, in a race to test whether a new vaccine really will protect against the virus before its expected rebound later in the year.

The first shots should go into volunteers' arms by the second week of August. A network of medical centers around the country is enrolling for the series of studies directed by the National Institutes of Health.

First, doctors will test different doses of the swine flu vaccine in healthy adults, including the elderly - two shots, given 21 days apart. If there are no immediate safety concerns, such as allergic reactions, the same testing quickly will begin in babies and children, said Dr. Anthony Fauci, head of NIH's National Institute of Allergy and Infectious Diseases.

"*The questions are clear. One is: is it safe*? And if so, what is the right dosage and number of doses? We need to ask that question both in healthy young adults, we need to ask the question in elderly individuals, and we need to ask the question in children," Fauci told CBS News medical correspondent Dr. Jennifer Ashton.

Will the results come in time to guide the government's debate on whether to roll out a mass vaccination campaign starting in mid-October, one expected to target mostly school-age children and young adults? – "It's going to be very, very close," Fauci told The Associated Press.

By early September, scientists should have the first clue - how much immune protection that initial dose triggers. How much protection the second dose adds will not be known for yet another month.

"We'll have a good idea by measuring the antibodies whether or not this vaccine is going to work," Dr. Kathryn Edwards from the Vanderbilt University Medical Center told Ashton.

As for safety, the new vaccine is expected to be similar to shots already given each year for seasonal flu. "It ought to be extremely safe," said Dr. William Schaffner, a vaccine specialist at Vanderbilt University, where a colleague will help test the vaccine.

But some question the government's track record. In 1976 the decision to vaccinate 43 million people against a similar strain of flu backfired. The outbreak never materialized and approximately 500 people suffered severe side affects, while 25 died, reports Ashton.

"*We frankly don't know why* there was that rare adverse event in 1976. And there's *never a hundred percent guarantee* that you're not going to see an adverse event now," Fauci said.

Included in the government studies are vaccines made by France-based Sanofi-Pasteur and CSL Ltd. Also Wednesday, CSL began a much smaller study of its vaccine in Australia, where the company is based.

Soon, vaccine from additional manufacturers - including the only non-shot version, a nasal spray - will begin separate, company-led studies in several thousand more volunteers.

But the NIH studies are specifically designed to test how the swine flu vaccine might be used by average Americans, with a set of tests to see how it reacts if given before, with or after the regular winter flu vaccine - which people are supposed to get as usual later this year.

First human trials of swine flu vaccine begin in Australia

The Guardian, 22 July 2009, 08:23 BST
https://www.theguardian.com/world/2009/jul/22/swine-flu-australia-vaccine-tests

Two biotechnology companies start injecting adult volunteers with swine flu vaccine. Experts say it could be two months before they can verify vaccine's effectiveness.

The world's first human trials of a swine flu vaccine have begun in Australia, drug company officials said today, as the global death toll from the virus rose to 700.

Two biotechnology companies have started injecting adult volunteers in the southern city of Adelaide. CSL, a Melbourne company, has 240 people in its seven-month trial starting today. Vaxine, from Adelaide, began trials on Monday with 300 people.

At least 41 people have died in swine flu-related illness in Australia, now well into its winter flu season.

"We're in the southern hemisphere, and that is where the problem is right now," Vaxine's research director, Nikolai Petrovsky, said. "The demand was here yesterday. We're right in the middle of a surge of swine flu cases where perhaps the US won't have to worry about it as much until their flu season hits, in six months.

Australia had confirmed 14,703 cases of swine flu, while the number of deaths from the virus globally is more than 700, according to the World Health Organisation, which recently stopped counting the number of cases worldwide. A surge in cases is predicted in September and October, when students and workers in the northern hemisphere return from summer vacation.

The Australian government has already ordered 21m doses of CSL's vaccine for use in Australia, should it be proved to work.

"We have a specific vaccine that we believe will be able to protect millions of people against this new H1N1 flu," Andrew Cuthbertson, CSL's director of research and development, told reporters. He called swine flu "a novel strain of influenza", and said the trial would determine the dose and schedule of the vaccination.

Petrovsky said it would be six to eight weeks before results would verify whether a vaccine was effective.

"There is no guarantee any of these vaccines will work," he said. "Swine flu is a very peculiar beast. It is a very different virus that we're dealing with. But we are hopeful."

Medical experts warned against rushing the vaccines through trials.

"I think it's important for the public to know that they're going to get a safe and effective vaccine," Andrew Pesce, president of the Australian Medical Association, told Sky News television. "No one will give anybody brownie points for putting out a vaccine that didn't work or caused harm."

In Britain, the UK's health protection agency (HPA) estimates there were 55,000 new cases of swine flu in England the week before last, including people visiting GPs and those who are looking after themselves at home.

The British pharmaceutical giant, GlaxoSmithKline, said in May it had agreed to supply nearly 130m doses of the swine flu vaccine to the UK, France, Belgium and Finland. It also said it would donate 50m doses to developing countries. The vaccine is expected to come before the end of the year.

Glaxo is one of several companies charged with producing a vaccine for H1N1 after the outbreak of the virus was declared a pandemic last month.

Kerry Capell

GlaxoSmithKline: A Swine Flu Windfall?

Business Week, 22 July 2009, 2:02 PM EST
https://web.archive.org/web/20090725053244/http:/www.businessweek.com/globalbiz/content/jul2009/gb20090722_800367.htm

British pharmaceutical giant GlaxoSmithKline (GSK) is set to reap billions as fear of the swine flu pandemic grows. The world's second-largest drug company has secured orders from 16 countries for 195 million doses of the vaccine it is developing against the H1N1 virus, which has killed more than 740 people worldwide.

The Brentford (England)-based drugmaker began production of its new flu vaccine in June and is on track to begin shipping the first doses in September. At a July 22 briefing to announce the company's second-quarter results, CEO Andrew Witty confirmed the number of orders is expected to be "substantially more" as the company currently is in discussions with 50 countries. While Britain has ordered 60 million doses of the vaccine, according to Witty, the U.S. has paid GSK $250 million to supply it with "pandemic products" such as the individual ingredients used in the vaccine. These include the antigen that prompts an individual's immune response and GSK's adjuvent technology, a sort of booster used to increase the vaccine's yield and potency.

GSK also announced it expects to increase annual production of its inhalable anti-viral flu treatment Relenza threefold, to 190 million doses, by yearend. Relenza sales for the three months ended June 30 were $99 million, up from just $5 million in the second quarter of 2008. Since the beginning of 2006, GSK has invested $2.5 billion to put in place the technology and capacity needed to meet demand. "Short of putting beds in the labs, we are throwing just about every resource we have into this," Witty says.

The Competition Heats Up

Witty reckons continued demand for GSK's flu drug and vaccine will likely boost sales in the second half of this year. GSK is one of several companies, including Novartis (NVS), Sanofi-Aventis (SNY), and Baxter International (BAX), racing to develop a swine flu vaccine.

While Witty says he is confident that GSK will meet its commitments, the company's total production capacity is still unknown. That's because the current strain of the swine flu virus is yielding less of the active ingredient or antigen needed to produce the vaccine than expected. (Because each flu virus varies, different strains produce varying levels of antigens.) Novartis also has conceded that the virus it's growing for its swine flu vaccine is producing a lower-than-expected yield. But Witty says based on current production levels, GSK should still be able to meet its commitments to governments around the world by early 2010.

With countries stepping up efforts to combat the pandemic, GSK's bottom line is likely to get a boost. However, Witty says that margins on both Relenza and the new vaccine are likely to be modest. GSK has a differentiated pricing structure for the new vaccine. Wealthier countries such as the U.S. and Britain will pay just under $10 per dose, the same price for the seasonal flu vaccine. Developing countries will pay a lower price, while GSK will donate 50 million doses of the vaccine to the World Health Organization for distribution to the world's poorest countries.

Generics Hurt U.S. Sales

Still, even the boost in sales of GSK's flu treatment and vaccine were not enough to offset the rapid slowdown in U.S. prescription drug sales due to competition from generic drugs. In the three months ended June 30, GSK's sales rose 15%, to $11 billion, on the back of the sterling's weakness against major currencies such as the dollar. In constant currency terms, sales fell by 2% mainly due to the performance of the company's U.S. pharmaceuticals business, where sales plummeted by 15%, to $3.8 billion, as former top sellers such as epilepsy treatment Lamictal faced generic competition. Net profits surged by 12%, to $2.5 billion.

The results, says Sanford C. Bernstein pharmaceuticals analyst Timothy Anderson, were slightly better than expected in large part thanks to the weakening of the British pound against the dollar. Witty acknowledged "there was still a lot more work to do" but claimed the company was "making progress in the right direction."

NBC NEWS

Volunteers sought for testing swine flu shots

NBC News, 23 July 2009, 12:49 AM +08
https://www.nbcnews.com/id/wbna32085899

The government called for several thousand volunteers for the first swine flu shots, in a race to test whether a new vaccine really will protect against this novel virus.

The government called Wednesday for several thousand volunteers to start rolling up their sleeves for the first swine flu shots, in a race to test whether a new vaccine really will protect against the virus before its expected rebound in the fall.

The first shots should go into volunteers' arms by the second week of August. A network of medical centers around the country is enrolling for the series of studies directed by the National Institutes of Health.

First, doctors will test different doses of the swine flu vaccine in healthy adults, including the elderly – two shots, given 21 days apart. If there are no immediate safety concerns, such as allergic reactions, the same testing quickly will begin in babies and children, said Dr. Anthony Fauci, head of NIH's National Institute of Allergy and Infectious Diseases.

Will the results come in time to guide the government's debate on whether to roll out a mass vaccination campaign starting in mid-October, one expected to target mostly school-age children and young adults? – "It's going to be very, very close," Fauci told The Associated Press.

By early September, scientists should have the first clue – how much immune protection that initial dose triggers. How much protection the second dose adds won't be known for yet another month.

As for safety, the new vaccine is expected to be similar to shots already given each year for seasonal flu. "It ought to be extremely safe," said Dr. William Schaffner, a vaccine specialist at Vanderbilt University, where a colleague will help test the vaccine.

Included in the government studies are vaccines made by Sanofi-Pasteur and CSL Ltd. Also Wednesday, CSL began a much smaller study of its vaccine in Australia, where the company is based.

Soon, vaccine from additional manufacturers – including the only non-shot version, a nasal spray – will begin separate, company-led studies in several thousand more volunteers.

But the NIH studies are specifically designed to test how the swine flu vaccine might be used by average Americans, with a set of tests to see how it reacts if given before, with or after the regular winter flu vaccine – which people are supposed to get as usual this fall.

The NIH's main study sites:

- University of Maryland School of Medicine, Baltimore.
- University of Iowa, Iowa City, Iowa.
- St. Louis University, St. Louis, Mo.
- Baylor College of Medicine, Houston.
- Children's Hospital Medical Center, Cincinnati.
- Emory University, Atlanta.
- Group Health Cooperative, Seattle.
- Vanderbilt University, Nashville, Tenn.

Children's Mercy Hospital in Kansas City and Duke University Medical Center partner with two of those hospitals and also will participate in part of the research.

U.S. panel prepares to OK swine flu vaccine trials

Reuters, 23 July 2009, 10:47 PM GMT+8
https://www.reuters.com/article/idUSN23382650/

Gaithersburg, Md., July 23 (Reuters) – The new pandemic H1N1 is causing a "brisk" flu season in the Southern Hemisphere and U.S. health officials said on Thursday they want to move swiftly to approve a vaccine to battle it.

Getting a vaccine approved as soon as possible is important, the U.S. Food and Drug Administration's Dr. Wellington Sun told a committee of experts who advise the FDA on vaccine policy.

"Time is really not on our side," Sun said.

"The 2009 H1N1 pandemic is a declared national emergency. The severity of disease seems comparable to seasonal" influenza, Sun added. But it could change, he said, and "We have to prepare for the worst."

He noted that the companies making H1N1 swine flu vaccine had a proven track record of safety and had been making seasonal flu vaccines for the U.S. market for years.

These vaccine makers are struggling to make the swine flu vaccine because they can produce less than a third of the usual amount, compared to seasonal flu vaccine strains, another expert told the meeting.

"Development work has indicated the existing reference strains have an expected yield of around 30 percent of H1N1 seasonal vaccine strains," said Dr. Jerry Weir, the FDA's director of the division of viral products.

This means makers may end up with fewer doses than expected of vaccine against the pandemic strain.

Earlier this month the World Health Organization reported that vaccine makers were not getting the expected yield from swine flu virus samples they were sent, which they have been growing in eggs to then purify and use to make vaccines.

AstraZeneca's MedImmune unit, Australia's CSL Ltd , Baxter International , GlaxoSmithKline Plc , Novartis AG and Sanofi-Aventis SA all are making H1N1 vaccines.

Spreading Virus

They will tell the FDA committee about what they have learned as they work with the virus, which spread globally in less than two months.

"This is clearly a brisk flu season," Dr. Anthony Fiore of the U.S. Centers for Disease Control and Prevention told the meeting.

H1N1 is the dominant strain, and while it is about as bad as a moderate seasonal flu, it is attacking younger people than seasonal flu usually does. Seasonal influenza kills between 250,000 and 500,000 people globally in an average year.

Global health officials are gearing up to vaccinate against both the seasonal flu, using a traditional cocktail that protects against the three most common strains, as well as against the pandemic H1N1 virus.

The U.S. National Institutes of Health reported on Wednesday it had assigned human trials of CSL's and Sanofi's vaccines to start in August at various academic centers and clinics. But the FDA must approve these before they can start.

Vaccine experts will test various doses of the H1N1 vaccine to see how large a dose people need to be protected, and also deliver it along with the seasonal flu vaccine to see if that will work.

The CDC's Dr. Nancy Cox said tests had confirmed that people who have received seasonal flu vaccines in the past have little or no immunity to the new H1N1 virus, including people in Europe who have received vaccines containing materials called adjuvants to boost the immune response to the immunizations.

The FDA committee will consider letting companies test the adjuvants in the United States in the hope of making limited supplies of the new H1N1 vaccine stretch further.

The CDC has a committee of vaccine advisers meeting next week to recommend who should get an H1N1 vaccine.

There will be enough swine flu vaccine, but maybe not at first: Health official

CP24 // The Canadian Press, 27 July 2009, 1:56PM EDT
https://www.cp24.com/mobile/there-will-be-enough-swine-flu-vaccine-but-maybe-not-at-first-health-official-1.420300?cache=yesclipId10406200text/html;charset=utf-80404/7.626236/7.626236/7.516026/7.516026

Toronto - Canadian officials are finalizing the number of doses of swine flu vaccine they expect will be enough to get the country through the upcoming flu season, ahead of a July 31 deadline for ordering the country's supply.

There will be a sufficient amount of vaccine for all those who want or need it, Ontario's chief medical officer of health said Monday, though she cautioned there may be a shortfall at first.

The initial amounts of vaccine will become available about mid-November, Dr. Arlene King said as public health officials from across Ontario met in Toronto to discuss pandemic preparations.

"It is important that we plan for the possibility that we're not going to have the amount that we need right from the outset," King said.

"So some of the considerations are looking at the epidemiology, our remote and isolated communities, health-care workers, those with pre-existing chronic diseases and those under the age of 50."

Lists of groups of people given priority for receiving the vaccine will be finalized in the fall, King said.

Higher risk groups for the pandemic H1N1 virus include infants, pregnant women, those with underlying health conditions and the morbidly obese, she said.

Canada has a contract with GlaxoSmithKline, which owns a flu vaccine plant in Ste-Foy, Que., to produce the necessary quantities. That plant is capable of producing 3.5 to four million doses per week, King said.

Health officials are determining the number of vaccines they will need to order so that everyone who needs it or wants it can be immunized, King said. That number was not yet available, but she said it will not be 100 per cent of the population.

People over the age of 50 are less at risk and those who have already had this H1N1 virus will have immunity, King said.

Public health officials should plan for a worse than usual flu season, but beyond that it's difficult to know how the H1N1 virus and three strains of seasonal flu will behave, she said.

"Influenza season is always full of surprises," King said.

But it is likely that during the fall remote and isolated communities, universities and military bases will see swine flu outbreaks, she told the meeting of public health officials.

Swine flu vaccine fast-tracked in Canada, U.S., Europe

CBC News // The Canadian Press, 29 July 2009, 3:50 PM ET
https://web.archive.org/web/20090802101640/http://www.cbc.ca/health/story/2009/07/29/swine-flu-vaccine.html

As pharmaceutical companies rush to make swine flu vaccine, regulators in Canada, the U.S. and Europe are gearing up plans honed over several years on fast-tracking influenza inoculations for a pandemic.

The approaches are not identical but are variations on a theme. Flu vaccines have been used safely for decades, and this pandemic version is just one more flu vaccine, the regulators say.

"Really, the same manufacturer will be making the same vaccine, and it's just considered as a [strain] switch," explained Dr. Elwyn Griffiths, director general of the biologics and genetic therapies directorate, the section of Health Canada that regulates vaccines.

Though they work under different laws, Health Canada, the U.S. Food and Drug Administration and the European Medicines Agency all intend to treat the pandemic vaccine as a supplement or amendment to existing flu vaccine licences, either for seasonal or pandemic vaccine.

The goal is to try to speed approval of the serum so that it can be used before the pandemic is over – if and when political or public health authorities decide vaccinating all or parts of the population is the right way to go.

"Remember, these are two separate decisions," says Dr. Norman Baylor, director of the FDA's office of vaccines research and review. Baylor uses his hands during a recent meeting in Gaithersburg, Md., to explain the demarcation between approving pandemic vaccine and ordering mass vaccination.

Licensing vs. using vaccine

"The decision to deploy the vaccine, that's over here. The decision to license the vaccine, that's over here," he says, holding his hands out to opposite sides of his body.

The second "over here" is the realm of the regulatory agencies, which have been working with the World Health Organization and each other for years striking plans for how to respond to the special demands of a pandemic. The impetus was the dangerous H5N1 virus, which kills about 60 per cent of people infected. Rapid action would be needed if it started a pandemic.

The work led to "Regulatory Preparedness for Human Pandemic Influenza Vaccines," a set of guidelines crafted by the WHO's expert panel on biological standardization.

Governments and their vaccine regulators realized that if pandemic vaccines were treated like a brand new vaccine – for instance, recently introduced products to protect against HPV or rotaviruses – clinical trials involving tens of thousands of people would be needed.

The pandemic would be over before the pandemic flu shots would be injected into anyone but the volunteers in the clinical trials.

Flu shot safety

That approach is obviously impractical. And regulators believe it is also unnecessary for flu vaccines, which have been reformulated countless times to target new virus strains in the half-century or so they've been in use.

Over that time, billions of flu shots have been administered. While people often complain of soreness at the site of the injection, serious side-effects from flu shots are extremely rare.

Unfortunately for those making decisions about this vaccine, the most famous side-effect incident linked to flu vaccine arose the last time there was a mass campaign to vaccinate against a swine flu virus.

An outbreak of swine influenza in the United States in early 1976 led to fears a pandemic was emerging. More than 40 million people in the U.S. were vaccinated. The pandemic never materialized, but roughly 500 people developed Guillain-Barré syndrome, a normally temporary paralytic condition. About 25 deaths were attributed to the vaccination program.

Science can't always explain why Guillain-Barré syndrome occurs, and it still can't answer why the 1976 vaccination program led to a spike in cases. Experts hope the modernization of flu vaccine manufacturing since 1976 will eliminate the risk of a repeat.

But they also know that even if this vaccine were to elevate the risk of developing Guillain-Barré, clinical trials are unlikely to detect it. Millions of doses of the 1976 vaccine were administered before U.S. authorities could see that there was a problem and that the problem was likely related to the vaccine.

Advanced licensing

So how will regulators proceed now?

To understand Canada's approach, it's helpful to first look at what the European Medicines Agency has done. It offered all flu vaccine manufacturers the chance to go through a special advance licensing process, producing a "core dossier" of safety and immunogenicity data on their manufacturing processes and their pandemic vaccines.

Three companies – Baxter International, GlaxoSmithKline and Novartis – went through the process, using H5N1 vaccines as their surrogate pandemic vaccines.

These "mock-up dossiers," as they are called, serve as the regulatory proof of safety and immunogenicity of any pandemic vaccine these manufacturers make. Manufacturers then apply for a "pandemic variation" to switch the subtype covered by the vaccine from H5 to the pandemic virus, in this case an H1N1.

"The whole concept of the mock-up vaccine relies on the fact that you can extrapolate to some extent the clinical efficacy data," explains Monika Benstetter, a media officer for the European Medicines Agency.

The agency says it can process a pandemic variation application in five working days, though it will still be up to national governments as to whether they want to use the fast-tracked vaccines.

Canada went through a similar process with the country's pandemic vaccine contractor, GlaxoSmithKline, Griffiths says. But whereas the European Medicines Agency actually licensed the pandemic vaccines, Canadian authorities held the approval in abeyance.

Small safety trial

"They [Europe] have licensed 'the mock' if you like,… and then all that was needed was a strain change," Griffiths explains. "We have come to the starting line, if I can put it that way, with the mock H5N1 and we did not license."

He insists the difference is a "nuance" that won't gum up the works in Canada. "We can use all those [mock-up dossier] data, switch in the new strain and away you go."

But Griffiths says Health Canada wants GlaxoSmithKline to do a small trial – involving 100 to 200 people, probably – to generate some safety and immunogenicity data for the H1N1 vaccine before the pandemic vaccine can get approval. Like its European counterpart, Health Canada can turn that application around in five days, he says.

As for the U.S., Baylor told the meeting of an FDA advisory committee on vaccines last week that the FDA intends to treat swine flu vaccine as a so-called strain change. No one on the expert advisory panel objected to the plan.

More than a strain change

Strain change is the regulatory tool the FDA uses to allow manufacturers to make the frequent adjustments needed for seasonal flu vaccine.

Flu shots have to be tweaked almost annually to keep up with the rapidly mutating influenza viruses. The strain change system lets manufacturers pull out virus strains no longer needed and slot in vaccine elements against newer viruses more likely to cause disease.

In the U.S. when seasonal flu vaccine is updated in this manner, no new studies are required; a strain change is considered a supplement to the original vaccine licence. (Canada uses a similar approach for seasonal flu vaccine, though it requires a small study each time.)

In this case, though, FDA officials have said they want manufacturers to do trials on the pandemic vaccine to validate that it's safe and ensure it is effective at the dose size that will be used. The data from those studies aren't expected to be available when swine flu vaccination programs start, however.

In fact, given the timing of when pandemic vaccines are likely to be approved and when dosing studies undertaken by companies and governments are likely to be completed, it is quite possible that dosing regimens – the amount of vaccine per shot and number of shots needed – could change midstream in countries that will have the first access to pandemic vaccine.

Health Panel Draws up Flu Vaccine Priority List

The Washington Post, 30 July 2009
https://www.washingtonpost.com/wp-dyn/content/article/2009/07/29/AR2009072903607.html?wpisrc=newsletter&wpisrc=newsletter&wpisrc=newsletter&sid=ST2009072903827
https://www.washingtonpost.com/wp-dyn/content/article/2009/07/29/AR2009072903607_2.html?wpisrc=newsletter&wpisrc=newsletter&wpisrc=newsletter&sid=ST2009072903827

A complicated list of who should get pandemic flu vaccine in the fall is now set. When the vaccine starts arriving in September, first in line will be pregnant women; the caretakers of infants; children and young adults; older people with chronic illness; and health-care workers.

That's the advice of a 15-member committee of experts, which met all day Wednesday at the Centers for Disease Control and Prevention in Atlanta to advise the federal government on vaccine policy.

The priority list names targeted groups and suggests the order in which they should be vaccinated. While acknowledging the potential for confusion, the committee chose the strategy because of the possibility that the epidemic will be peaking within four to six weeks of when the vaccine becomes available.

"The results of this meeting will kick planning into high gear," said Pascale Wortley of the CDC's Immunization Services Division. "This is a watershed moment."

Luiza Duszynski, a nurse, administers a dose of flu vaccine to Holly Pyke at the Royal Adelaide Hospital in Adelaide, Australia (By Michael Laurie)

All that's missing is the vaccine, knowledge of how well it works and the nitty-gritty details of how to deliver it to people's arms and noses.

Manufacturers expect to deliver about 40 million doses of vaccine to the government and private distributors in September, and another 80 million doses in October. About 80 million doses a month will be delivered after that.

The vaccine will come in two forms: the traditional flu shot and a "live" vaccine squirted into the nose that contains a weakened version of the new virus.

Unlike nearly every previous effort to get people to use flu vaccine, the promotion of the pandemic vaccine won't first try to reach the elderly. That's because people 65 and older have contracted the new strain at the lowest rate of any age group and appear to be largely protected because of exposure to other distantly related flu strains that circulated decades ago.

The top-priority group includes about 160 million people and contains five populations: pregnant women; household contacts of children younger than 6 months; health-care and emergency medical services workers; everyone 6 months to 24 years old; and people 25 to 64 who have conditions that put them at higher risk of serious infection and death.

Only a fraction of each targeted group is expected to want the vaccine. Once the priority groups have been immunized, the vaccine can be offered to healthy adults ages 25 to 64, and after them, people 65 and older, the committee advised.

Health departments, clinics and private physicians will continue to urge the elderly to get the seasonal flu vaccine, which contains three strains circulating the world along with the new one.

The groups were selected because of long-standing knowledge of influenza outbreaks and the particular behavior of the new virus, which emerged in Mexico and Southern California in late April. Derived from two strains carried in pigs, the new influenza A (H1N1) virus was originally called swine flu.

Pregnant women account for about 6 percent of H1N1 deaths, as well as cases serious enough to require hospitalization, Anthony Fiore, a physician and epidemiologist at the CDC, told the Advisory Committee on Immunization Practices.

Children younger than 6 months do not produce a strong immune response to flu vaccine and are best protected by keeping them away from the virus, which is spread by coughing, sneezing and touching. Physicians, nurses and paramedics are high on the list because of the work they do.

In outbreaks during the spring, people ages 12 to 18 were hospitalized at twice the rate of people ages 19 to 24 and five times the rate of those 25 to 49. Of the 302 U.S. deaths recorded so far, more than half of those patients had an underlying chronic illness or medical condition such as asthma, diabetes, immune deficiency or morbid obesity.

In the "Asian flu" pandemic of 1957, which many experts believe is a model for the current one, many communities experienced an explosive spread of the virus once schools opened and the weather cooled.

Although CDC experts originally suggested making age 18 the ceiling of the healthy-young-people target group, the committee raised the age to 24 to include college students.

Some of the vaccine will be stored in multi-dose vials containing thimerosal, an antibacterial additive that contains mercury. But there will also be single-dose syringes without thimerosal, a substance that some assert is harmful to children.

Among the many unanswered questions is whether two doses will be necessary to provide full protection, how close in time two shots can be given and how big the dose will be. Vaccination programs may start before the answers are known.

Clinical trials in which the prototype vaccine will be tested in hundreds of children and adults are just beginning. Data on the effectiveness of one shot will be available in mid-September; two shots, in late September.

[Kate Couric]

Web Exclusive: Sebelius on Vaccine Fears

CBS News, 30 July 2009
https://web.archive.org/web/20100104120146/http://www.cbsnews.com/stories/2009/07/30/eveningnews/main5199450.shtml

(CBS) Couric: Thimerosol, a preservative which was taken out of childhood vaccines a while ago, because there was fear it could be linked to autism, is being used in some batches of the H1N1 vaccine. Are you concerned that will keep some parents from having their children vaccinated?

Sebelius: Well, we want to make it clear that this is a voluntary vaccination program. But study after study, scientist after scientist, has determined that there really is no safety risk with thimerosol. There is concern about parents of why autism rates are rising. And, as you know, we've got some special NIH studies, thanks to the president, focused on just what is going on.

But thimerosol has been proven to be safe. It's used in seasonal vaccine- seasonal flu vaccine. And, again, we want to assure people that that-- the scientists, again, have confirmed-- that there is really a safe factor with using thimerosol .It's an effective preservative and one that we think actually adds to the likelihood that we'll have a safe vaccine for a while to come.

Couric: As you know, there's a very small but passionate group of people who are convinced that childhood vaccines, in general, or the way they're scheduled, are connected to autism and other neurodevelopmental disorders. Are you concerned there will be a backlash by that vocal group against this vaccine?

Sebelius: Well, I think what- what parents have to understand and, you know, I'm a mom and I know you're a mom - is certainly the safety and security our children is of primary importance. It's important to the president. And what we know is that this disease targets kids. So that we want parents to feel comfortable to get their children vaccinated, because, unfortunately, seasonal flu - year in and year out – kills 36,000 people. Hospitalizes a couple hundred thousand people. So we are taking every precaution. But based on the science. And the science, again, continues to indicate that the ingredients we're anticipating using in this vaccine are safe to use.

Tests will be done. We're going to listen to the science and not release a vaccine until we feel we've got the dosage right and that it's safe and effective for people to – to be vaccinated. And – again, children over age of six months – young adults with underlying health condition, pregnant women, which – who unfortunately are dying in larger numbers – than in seasonal flu, are affected by this virus.

And we think it's important, certainly, for health care workers who will be coming in contact with ill people to be at the front of this line. So those are really the priority groups, along with caregivers and parents of infants under six months old. The infants aren't recommended to get the vaccination themselves. So we want to make sure that the caregivers who come in close proximity to those infants actually are at the front of the line for vaccinations.

Couric: Initially, you had said children between the ages of six months and 18 years. And I've noticed that you have extended that to age 24. Why?

Sebelius: Well, we're particularly concerned with students in college dormitory settings. There is evidence that, in college dorms-- and camp-like settings, this also continues to spread very rapidly. So the age increase really focuses on that target population, but certainly, at the age of 24, with anyone with underlying health conditions, again, is strongly recommended to get the vaccine, once it's available. And, again, we're targeting mid October. But, Katie, I think what we want to do is remind parents that there's a lot that could be done today as your child is getting ready to go back to school.

Teaching basic hygiene. Making sure that hand washing, which often doesn't happen in a school setting, is part of the daily routine. You know, wash your hands frequently. Cough into a handkerchief or a Kleenex or a sleeve. Don't use your hands to cover a cough and sneeze.

You, certainly, please keep your children home if they are sick. I know it's an inconvenience to miss work or find alternative-- daycare arrangements, but this virus spreads very, very quickly. Sending your child to school with the flu introduces the flu to all of his or her playmates and friends. And we're really trying to contain the flu as much as possible until we have an effective vaccine available.

Couric: Since the vaccine won't be available, Madam Secretary, 'til mid October, are you worried about significant outbreaks happening when schools start in September?

Sebelius: Well, what we know is the virus hasn't gone away. We think we have about a million cases right now. Recently it was identified that some-- some kids who were here in Washington paging at the capital have caught the flu. And they are staying home and not introducing that flu to members of Congress who we need to continue to work hard until their August recess.

We know it has spread through summer camps. And it's likely to present itself when schools reopen. So, yes, there-- there are concerns, which is, again, why it's so important to take the basic steps of some isolization.

Don't get on an airplane. Don't send your child to school. Stay home yourself and try to limit how we spread this virus until, again, we have vaccines available. And then, hopefully, parents will feel comfortable about having their vaccinated, keeping them safe and secure as we continue on with the school year.

The New York Times

Andrew Pollack

**A worker gives FluMist by MedImmune,
which is to make more Swine Flu Vaccine than planned**

The New York Times, 30 July 2009
https://www.nytimes.com/2009/07/31/business/31flumist.html

As the nation girds for a possible swine flu pandemic, one of the big weapons may come from an unexpected source — a vaccine squirted or dropped into the nose.

MedImmune, which already makes the nasal spray vaccine FluMist for seasonal flu viruses, says it is on track to produce about five times as much swine flu vaccine as it had expected so much, in fact, that it will run out of nasal spray devices and is looking to administer the vaccines with droppers instead.

A nasal spray vaccine could be a strong weapon against swine flu because makers of conventional flu shots have reported problems producing their vaccines.

If nasal spray vaccines emerge as a central player against swine flu, it would represent a reversal of fortune for MedImmune’s efforts in the field. As a vaccine for seasonal influenza, its FluMist has been a flop from a marketing standpoint, accounting for only a few percent of the inoculations Americans receive each year.

But it appears to have a manufacturing edge. Because its vaccine uses a live but weakened virus, MedImmune uses a different viral strain than the makers of flu shots, which contain an inactivated virus.

Each approach uses chicken eggs as the culture for growing its virus strain, but flu shot makers say the strain of swine flu virus they are using is growing more slowly than expected. MedImmune’s strain, meanwhile, is growing faster than expected.

As a result, MedImmune, a subsidiary of AstraZeneca, says it can make 200 million doses by next March, about five times what it had expected.

Robin Robinson, who heads procurement of the pandemic vaccine for the Department of Health and Human Services, said MedImmune alone accounted for 12 million of the 20 million doses already produced by the five companies under contract to the government.

Dr. Robinson said that the other drug makers were resolving their production problems and would catch up. He said 120 million doses should be available by October, without counting on any extra production from MedImmune. But if the extra nasal spray doses can be used, Dr. Robinson said, "our supply could possibly increase by a very large amount.”

The problem for MedImmune is that the unexpected production surge left the company short of the sprayers used to squirt the vaccine into the nose. It can supply only about 40 million doses in sprayers by March.

"We now are sitting on a surplus of potentially 150 million bulk doses," Bernardus N. M. Machielse, executive vice president for operations, said in an interview.

BD, supplier of the sprayers, said Thursday that it was running its sprayer factory in Columbus, Neb., round the clock to increase annual capacity to 70 million sprayers — up from 20 million.

But even that will not be enough. So MedImmune wants to use droppers in addition to sprayers. Some early clinical trials of the vaccine were conducted with droppers, so the company hopes to win approval from the Food and Drug Administration to use them.

Pandemic vaccines could bolster the total sales of AstraZeneca, the pharmaceutical giant based in London that acquired MedImmune, a Maryland biotechnology company, for $15.6 billion in 2007.

The government has ordered 12.8 million doses of pandemic vaccine from MedImmune for $151 million, Dr. Robinson said. AstraZeneca might get many hundreds of millions more in sales if the government buys the rest of the 40 million or so doses in sprayers and potentially the some 150 million doses in droppers.

Simon Lowth, AstraZeneca's chief financial officer, told analysts on Thursday that FluMist had a lower-than-average profit margin and that the pandemic vaccine, being sold under government contract, had margins that are "lower still."

The pandemic might also allow AstraZeneca to achieve a foothold outside the United States, the only country that has approved FluMist. The company is applying for approval in other countries and is talking to the World Health Organization about supplying some pandemic vaccine to poorer countries, David Brennan, its chief executive, said Thursday.

When MedImmune agreed to buy Aviron, the developer of FluMist, in 2001, executives predicted sales would grow to more than $1 billion a year. But in 2008, the best year yet for FluMist, sales reached only $104 million.

Several missteps nullified any appeal a needle-less vaccine might have. When it was initially sold in 2003, FluMist was priced at about $50, two to six times as much as a flu shot. And FluMist had to befrozen, a problem for some doctors' offices.

Because of safety concerns FluMist was approved only for healthy people 5 to 49 years old. But those are not typically the people who get flu vaccines.

FluMist is now approved for children as young as 2, it can be refrigerated instead of frozen and the wholesale price is down to $18.95.

H1N1 Pandemic:
Pentagon Planning Deployment of Troops in Support of Nationwide Vaccination
Militarization of public health in the case of emergency is now official

Global Research, 31 July 2009
https://web.archive.org/web/20091207150056/http://www.globalresearch.ca/index.php?context=va&aid=14580

According to CNN, the Pentagon is "to establish regional teams of military personnel to assist civilian authorities in the event of a significant outbreak of the H1N1 virus this fall, according to Defense Department officials."

"The proposal is awaiting final approval from Defense Secretary Robert Gates.

The officials would not be identified because the proposal from U.S. Northern Command's Gen. Victor Renuart has not been approved by the secretary.

The plan calls for military task forces to work in conjunction with the Federal Emergency Management Agency. There is no final decision on how the military effort would be manned, but one source said it would likely include personnel from all branches of the military.

It has yet to be determined how many troops would be needed and whether they would come from the active duty or the National Guard and Reserve forces.

Civilian authorities would lead any relief efforts in the event of a major outbreak, the official said. The military, as they would for a natural disaster or other significant emergency situation, could provide support and fulfill any tasks that civilian authorities could not, such as air transport or testing of large numbers of viral samples from infected patients.

As a first step, Gates is being asked to sign a so-called "execution order" that would authorize the military to begin to conduct the detailed planning to execute the proposed plan.

Orders to deploy actual forces would be reviewed later, depending on how much of a health threat the flu poses this fall, the officials said." (CNN, Military planning for possible H1N1 outbreak, July 2009)
https://web.archive.org/web/20091201173526/http://www.cnn.com/2009/US/07/28/military.swine.flu/

The implications are far-reaching.

The decision points towards the militarization of civilian institutions, including law enforcement and public health. A nationwide vaccination program is already planned for the Fall.

The pharmaceutical industry is slated to deliver 160 million vaccine doses by the Fall, enough doses to vaccinate more than half of America's population.

The Pentagon is already planning on the number of troops to be deployed,. with a view to supporting a mass vaccinaiton program.

It is worth noting that this involvement of the military is not being decided by the President, but by the Secretary of Defense, which suggests that the Pentagon is, in a key issue of of national interest, overriding the President and Commander in Chief. The US Congress has not been consulted on the issue.

This decision to mobilise the Armed Forces in the vaccination campaign is taken *in anticipation of a national emergency*. Although no national emergency has been called, the presumption is that a national public health emergency will occur, using the WHO Level 6 Pandemic as a pretext and a justification.

Other countries, including Canada, the UK and France may follow suit, calling upon their Armed Forces to play a role in support of the H1N1 vaccination program.

US Northern Command

Much of the groundwork for the intervention of the military has already been established. There are indications that these "regional teams" have already been established under USNORTHCOM, which has been involved in preparedness training and planning in the case of a flu pandemic (See U.S. Northern Command - Avian Flu. USNORTHCOM website).
=> https://web.archive.org/web/20100213103744/http://www.northcom.mil/Avian%20Flu/index.html

Within the broader framework of "Disaster Relief", Northern Command has, in the course of the last two years, defined a mandate in the eventuality of a public health emergency or a flu pandemic. The emphasis is on the militarization of public health whereby NORTHCOM would oversee the activities of civilian institutions involved in health related services.

According Brig. Gen. Robert Felderman, deputy director of USNORTHCOM's Plans, Policy and Strategy Directorate: "USNORTHCOM is the global synchronizer – the global coordinator – for pandemic influenza across the combatant commands**"**(emphasis added)
See Gail Braymen, USNORTHCOM contributes pandemic flu contingency planning expertise to trilateral workshop, USNORTHCOM, April 14, 2008, and USNORTHCOM: Pandemic Influenza Chain Training (U) =>
https://web.archive.org/web/20100106084531/http://www.northcom.mil/news/2008/041408.html &
https://web.archive.org/web/20100213103708/http://www.northcom.mil/Avian%20Flu/docs/Pandemic_Influenza_Training_Brief.pdf

"Also, the United States in 1918 had the Spanish influenza. We were the ones who had the largest response to [a pandemic] in more recent history. So I discussed what we did then, what we expect to have happen now and the numbers that we would expect in a pandemic influenza."

The potential number of fatalities in the United States in a modern pandemic influenza could reach nearly two million, according to Felderman. Not only would the nation's economy suffer, but the Department of Defense would still have to be ready and able to protect and defend the country and provide support of civil authorities in disaster situations. While virtually every aspect of society would be affected, "the implications for Northern Command will be very significant."

"[A pandemic would have] a huge economic impact, in addition to the defense-of-our-nation impact," Felderman said. The United States isn't alone in preparing for such a potential catastrophe. (Gail Braymen, op cit)

Apart from the CNN dispatch and a FOX news report, there has been virtually no mainstream press coverage of this issue. No statement has been made by USNORTHCOM. The Fox New Report suggests that US troops would be involved in organising military quarantines.

Is it safe? U.S. vaccine experts want to build trust

Reuters, 31 July, 2009, 3:40 am
https://www.reuters.com/article/us-flu-vaccine-safety-analysis-idUSTRE56T63E20090730

Likewise for a meeting on Wednesday of advisers who decide who will be first in line to get the vaccine, which drug companies are racing to make, test and distribute all within the space of a few weeks.

Registered nurse Vicky Debold, on the board of the National Vaccine Information Center, which questions vaccine safety, is also a member of the FDA's Vaccine and Related Biological Advisory Committee. The group's founder, Barbara Loe Fisher, asked extensive questions at the meeting.

Lyn Redwood, president of SafeMinds, a group that advocates about potential links between mercury and neurological disorders, asked questions at a meeting on Wednesday of vaccine advisers to the Centers for Disease Control and Prevention.

The U.S. federal government is more ready than it has ever been for questions, criticisms and fear of vaccines – a state of preparedness more than 30 years in the making.

"We know that there are some people who are reluctant to vaccinate and they have heard information that concerns them," Dr. Anne Schuchat of the U.S. Centers for Disease Control and Prevention told reporters late on Wednesday.

The concerns:

- Will a vaccine against a swine-like virus cause more adverse reactions than a seasonal flu vaccine?
- Will special additives called adjuvants cause reactions?
- Will the vaccines contain thimerosal, a mercury-based preservative that critics say might cause problems?
- Is it dangerous to vaccinate against both seasonal flu and the new H1N1 flu at the same time?

Quick Spread

H1N1 swine flu has swept around the world in weeks, infecting millions and killing more than 800 by official counts. While only a "moderate" pandemic by World Health Organization standards, it could worsen as temperatures cool in the Northern Hemisphere, making conditions better for viruses.

Five companies are making H1N1 vaccine for the U.S. market -- AstraZeneca's MedImmune unit, Australia's CSL Ltd, GlaxoSmithKline Plc, Novartis AG and Sanofi-Aventis SA.

CSL has started trials of its vaccine in people and the U.S. National Institutes of Health starts trials next month. They will compare vaccines with and without adjuvants – ingredients that boost the immune system response to a vaccine.

Adjuvants are used in flu vaccines in Europe but not the United States and although it would be possible to get a U.S. license under Emergency Use Authorization, officials have chosen to use vaccines without it for now.

Companies such as Glaxo say they will be ready to start vaccinating people in Europe just as the first data from those trials start emerging at the end of September. Some have questioned this speed.

The FDA's Dr. Hector Izurieta said the agency had set up an exceptionally extensive network for what is known as post-marketing surveillance.

"If something happens after vaccination, the vaccine will be accused," Izurieta told last week's meeting. "There will be many, many reports of things that could be, or not, associated with vaccination."

Vaccine regulators and public health experts are painfully aware of the last swine flu vaccination campaign. In 1976, the U.S. government rushed out a mass immunization against a swine flu virus that never spread off one military base.

Several hundred cases of a rare, paralyzing neurological disease called Guillain-Barre syndrome were reported afterward and although no clear link has ever been found to the vaccine, the incident made many people mistrustful of immunizations.

More recently, fears center on thimerosal, taken out of most vaccines after activists claimed it could cause autism – a link discredited by many scientific studies but one that some vocal activists say is still valid.

Instead of fighting the perception, Schuchat said the CDC will roll with it. "There will be thimerosal-free formulations available for those people who are interested in that sort of preparation," she said.

THE LANCET

Supply and safety issues surrounding an H1N1 vaccine

The Lancet, 1 August 2009, 374(9687): 358
DOI: https://doi.org/10.1016/S0140-6736(09)61395-7

Last week, Australia and the USA announced that they would begin trials of an H1N1 vaccine. Vaccination against H1N1 will be an important development in controlling the impact of the pandemic. However, several thorny issues exist around vaccine manufacture and approval.

All countries will require the vaccine but current global manufacturing capacity will not be able to meet this demand. Additionally, experts think that individuals might need two doses of the vaccine instead of one, reducing capacity further. Vaccine manufacturers are also struggling to produce good vaccine yields with the H1N1 seed virus.

One way to ease these supply problems is the use of adjuvants in a vaccine. On July 7, WHO's Strategic Advisory Group of Experts on Immunization recommended that vaccine formulated with oil-in-water adjuvants and live-attenuated influenza vaccines should be promoted to help increase the global supply of a vaccine and because they are better at protecting against strain variations. Yet there are signs that the USA might not follow this recommendation. "Adjuvant use would be contingent upon showing that it was needed or clearly beneficial", Jesse Goodman, acting chief scientist and deputy commissioner of the Food and Drug Administration told a press briefing on July 17. The USA must support the use of dose-sparing strategies to avoid depletion of an already short vaccine supply.

As well as availability, safety of an H1N1 vaccine is a concern. Many national regulatory agencies have set-up fast-track approval processes for the H1N1 vaccine, which means that a vaccine might be licensed without the usual safety and efficacy data requirements. Vaccine safety will therefore have to be monitored through post-marketing surveillance. But some fear a repeat of the 1976 H1N1 outbreak in the USA, where mass vaccination was associated with complications, which stopped the campaign and led to the withdrawal of the vaccine.

Countries need to assess carefully the risks and benefits of rapid approval of an H1N1 vaccine, especially since the disease has so far been mild with most patients making a full recovery. They must also ensure that they have strong post-marketing surveillance in place before rolling out a vaccine.

Swine flu vaccine priorities being set

WA Today, 3 August 2009
https://web.archive.org/web/20090922094230/http://www.watoday.com.au/breaking-news-national/swine-flu-vaccine-priorities-being-set-20090804-e7fn.html

Australia's leading public health officials will meet later this week to decide who'll get swine flu vaccine first when it becomes available.

Queensland's chief health officer Dr Jeannette Young says a swine flu vaccine is expected to be available in October.

Dr Young says the Australian Health Protection Committee, comprising federal and state health officials and responsible for co-ordinating a national approach to public health emergencies, will meet in Melbourne on Thursday.

"I have a meeting later on this week to discuss it with the other jurisdictions in the commonwealth so we can work through how we'll do it on a national basis," Dr Young told reporters on Monday.

Dr Young indicated that medical personnel, pregnant women and *indigenous Australians* were likely to be priorities for vaccination.

Under the current "protect phase" of the swine flu pandemic, at risk groups also included those with respiratory conditions, heart disease, diabetes, renal disease, the morbidly obese and those with immunosuppression.

However, prioritisation of immunisation will be decided on a national basis, Dr Young said.

REUTERS

WHO sees first swine flu vaccines approved in September

Reuters, 6 August 2009, 9:04 PM GMT+8
https://www.reuters.com/article/idUSTRE57530A/

Geneva (Reuters) **-** The development of new vaccines to combat H1N1 swine flu is on schedule and first regulatory approvals are possible in September, the World Health Organization said Thursday.

Marie-Paule Kieny, WHO director of the Initiative for Vaccine Research, said manufacturers had initially reported poor yields in making vaccine but this was now improving.

"We are on track in development," Kieny told reporters.

First results from clinical trials are expected early next month and these tests will show whether one or two doses are needed to provide immunity, she added.

The current outbreak, declared a pandemic on June 11, is the fastest ever pandemic and could eventually affect 2 billion people, underscoring the need to get vaccines to market as quickly as possible.

Leading flu vaccine makers include Sanofi-Aventis, GlaxoSmithKline, Novartis, Baxter, CSL and Solvay.

World Health Organization

Safety of pandemic vaccines:
Pandemic (H1N1) 2009 briefing note 6

Geneva, WHO, 6 August 2009
https://web.archive.org/web/20090806192723/http://www.who.int/csr/disease/swineflu/notes/h1n1_safety_vaccines_20090805/en/index.html

Geneva – WHO is aware of some media reports that have expressed concern about the safety of vaccines for pandemic influenza. The public needs to be reassured that regulatory procedures in place for the licensing of pandemic vaccines, including procedures for expediting regulatory approval, are rigorous and do not compromise safety or quality controls.

Vaccines are among the most important medical interventions for reducing illness and deaths during a pandemic. However, to have the greatest impact, pandemic vaccines need to be available quickly and in large quantities.

During the 1957 and 1968 pandemics, vaccines arrived too late to be used as an effective mitigation tool during the more severe phases of the pandemics. Influenza vaccines had not yet been developed when the 1918 pandemic swept around the world, eventually killing an estimated 50 million people.

In 2007, as part of preparedness for an influenza pandemic, WHO worked together with health officials, regulatory authorities, and vaccine manufacturers to explore a broad range of issues surrounding the regulatory approval of pandemic vaccines. [1]

Ways were sought to shorten the time between the emergence of a pandemic virus and the availability of safe and effective vaccines. Different regulatory pathways were assessed, and precautions needed to ensure quality, safety, and effectiveness were set out in detail.

Fast-track procedures for approval

Regulatory authorities have shown great flexibility in developing procedures for fast-tracking the approval and licensing of pandemic vaccines.

In some cases, pandemic vaccines are not regarded by regulatory authorities as entirely "new" vaccines, as they build on the technology used to produce vaccines for seasonal influenza, established procedures for testing and regulatory control, and an extensive body of safety data.

In such cases, approval procedures are similar to those applied to "strain changes" made each year when seasonal vaccines are modified to match circulating viruses in the Northern and Southern Hemispheres.

Specific regulatory procedures have been devised to expedite the approval of pandemic vaccines. In the USA, for example, fewer data are required when the manufacturer already has a licensed influenza vaccine and intends to use the same manufacturing process for its pandemic vaccine.

In the European Union, the European Medicines Agency uses a rolling review procedure whereby manufacturers can submit sets of data for regulatory review as they become available, without having to wait until all data can be submitted together in a single formal application.

Also in Europe, some manufacturers have conducted advance studies using a so-called "mock-up" vaccine. Mock-up vaccines contain an active ingredient for an influenza virus that has not circulated recently in human populations and thus mimics the novelty of a pandemic virus. Such advance studies can greatly expedite regulatory approval.

Special safety concerns

Influenza vaccines have been used for more than 60 years and have an established record of safety in all age groups. While some serious adverse events have been reported, these have been rare.

Nonetheless, special safety issues will inevitably arise during a pandemic when vaccine is administered on a massive scale. For example, adverse events too rare to show up even in a large clinical trial may become apparent when very large numbers of people receive a pandemic vaccine.

Some adverse events will be coincidental – that is, associated in time with vaccine administration, yet not directly caused by the vaccine. Genuine adverse events directly caused by the vaccine may also occur, but cannot be predicted in advance. Given the safety record of seasonal vaccines, such events are expected to be rare.

Time constraints mean that clinical data at the time when pandemic vaccines are first administered will inevitably be limited. Further testing of safety and effectiveness will need to take place after administration of the vaccine has begun.

For these reasons, WHO advises all countries administering pandemic vaccines to conduct intensive monitoring for safety and efficacy, and many countries have plans in place for doing so. On the positive side, mass vaccination campaigns can generate significant safety data within a few weeks.

International sharing of data from such post-marketing surveillance will be vital in guiding risk-benefit assessments and determining whether changes in vaccination policies are needed. WHO has developed standardized protocols for data collection and reporting in real-time, and will communicate findings to the international community via its web site.

WHO sees Swine Flu vaccination from next month

Reuters, 6 August 2009, 10:26 PM GMT+8
https://www.reuters.com/article/flu-vaccines-who/update-1-who-sees-swine-flu-vaccination-from-next-month-idUKL633241920090806/

Geneva/London, Aug 6 (Reuters) – The first vaccines to combat H1N1 swine flu should be approved and ready for use in some countries from September, the World Health Organisation said on Thursday.

Marie-Paule Kieny, WHO director of the Initiative for Vaccine Research, also said vaccine production yields were improving, following a disappointing start that triggered some worries about supplies.

One of the virus strains used by vaccine makers now seems to be yielding the same amount as seasonal vaccine, while early indications were that pandemic H1N1 yields might be only 30 percent of normal.

"I don't want to say too early that the question has been resolved but it really seems that we have found a way to go round this problem," Kieny told reporters. "We are on track in development."

First results from clinical trials are expected early next month and these tests will show whether one or two doses are needed to provide immunity -- another big swing factor in determining how many people can be vaccinated.

Once initial clinical trial results are in, regulators will be able to approve the vaccines from next month and the first countries are expected to start mass vaccination programmes, Kieny added.

The H1N1 flu outbreak, declared a pandemic on June 11, has spread around the world and could eventually affect 2 billion people, according to WHO estimates.

Fears the strain could become resistant to the anti-viral drug Tamiflu [ROG.VX] [GILD.O] have underscored the need to get vaccines to market quickly. The H1N1 vaccines would be given separately from regular seasonal flu shots.

Leading flu vaccine makers include Sanofi-Aventis [SASY.PA], GlaxoSmithKline [GSK.L], Novartis [NOVN.VX], Baxter [BAX.N], CSL [CSL.AX] and Solvay [SOLB.BR].

WHO Director-General Margaret Chan has said the H1N1 virus is stable and there were no signs of it mixing with other more dangerous types of influenza such as the deadly H5N1 bird flu strain.

At present, patients with mild symptoms generally do not need any medicines to recover, and Chan has stressed hospital visits are not necessary unless those infected with flu have certain warning signs.

These include long-lasting high fever in adults and a lack of alertness in children. Pregnant women and people with health problems including diabetes are also vulnerable to more severe effects from the new flu strain.

Fast-Track Approval 'Safe'

The WHO said vaccines had to be available quickly and in large quantities to have the greatest impact and it insists that fast-track approval will not jeopardise safety.

Vaccines arrived too late in the 1957 and 1968 flu pandemics to be of much use, and flu vaccines had not been developed in the 1918 "Spanish flu" pandemic which killed an estimated 50 million people.

Some concerns have been raised because of serious side effects and 30 deaths seen during a U.S. swine flu vaccination in 1976.

Kieny said vaccine production and purity levels had improved significantly since but safety issues could arise during a pandemic when a vaccine is administered on a mass scale, even if they did not show up in safety trials.

As a result, countries are being advised to conduct intensive monitoring as the vaccination campaign goes on.

NBC NEWS

WHO: Swine flu shots on track for next month

NBC News, 6 August 2009, 9:21 PM GMT+8
https://www.nbcnews.com/id/wbna32312913

The World Health Organization says vaccine manufacturers are on track to start delivering the first batches of swine flu vaccine in September, the WHO said Thursday.

Swine flu vaccine manufacturers are on track to start delivering the first batches of it in September, the World Health Organization said Thursday.

Marie-Paule Kieny, WHO's vaccine director, said several drug makers have started testing swine flu vaccine in humans, and that early safety results should be available next month, clearing the way for its use. Kieny also insisted that speeding the vaccine to the market will not compromise its safety.

WHO has recommended the first recipients of the vaccine be health care workers, perhaps followed by pregnant women and people with underlying health problems.

Kieny said WHO expects to see reports of side effects once the vaccine is given to millions of people, but that deadly side effects will be rare. Vaccines commonly provoke reactions such as nausea, fever, pain from the injection, and diarrhea.

She said the agency would work with country officials to detect any sign the vaccine might cause more worrying side effects, like Guillain Barre syndrome, a temporary paralysis disorder reported by hundreds of people after the U.S.'s disastrous 1976 immunization campaign against another variant of swine flu.

To fight the current pandemic , or global outbreak, half a dozen major pharmaceutical companies located in the United States, Europe and Australia are developing their own swine flu vaccines, which will have to be approved by drug regulatory authorities in each country where they are used.

It is the first time that companies have rushed to produce a vaccine within months to fight a flu pandemic. Health officials expect swine flu to surge in the fall, with the return of the regular flu season.

On Wednesday, Swiss drug maker Novartis said it had begun testing its swine flu vaccine in Europe, and would begin selling it long before completing its safety tests next year.

Last month, Australian pharmaceutical CSL started trials on its vaccine candidate.

Kieny said ongoing tests in Australia, China, Germany, the United Kingdom and the United States should inform officials how many doses of the vaccine are required. Many experts think people will need two shots to be protected.

Europe and the U.S. both have fast-track approval systems to make the swine flu vaccine available before extensive safety tests are completed.

In a statement on its Web site, WHO said Thursday "the public needs to be reassured" that procedures for approving swine flu vaccines "are rigorous and do not compromise safety or quality controls."

To increase the global supply of swine flu vaccines, WHO recommends that countries use ones containing adjuvants, a component that stretches the vaccine's active ingredient and boosts the body's immune response. Adjuvants are commonly used in flu vaccines in Europe, but there are no licensed flu vaccines with adjuvants in the U.S.

There is little or no information on how safe flu vaccines with adjuvants are in pregnant women and children – two of the groups most at risk in the pandemic.

Kieny dismissed concerns adjuvanted vaccines might not be ideal for groups such as pregnant women. "We see no apparent safety signal," she said. "There is no safety concern with using adjuvanted vaccine."

РИА НОВОСТИ

Экспериментальные серии вакцины против гриппа A/H1N1 выпустили в Уфе

РИА Новости, 12 августа 2009, 14:30
https://ria.ru/20090812/180629732.html

УФА, 12 августа – РИА Новости, Рамиля Салихова. Уфимские микробиологи завершили работу над созданием первой инактивированной отечественной вакцины против гриппа A/H1N1 на базе филиала ФГУП "НПО "Микроген" МЗ РФ "Иммунопрепарат", три экспериментальные серии вакцины в ближайшие дни отправят в Москву, сообщила в среду пресс-секретарь филиала Гузель Юсупова.

"На создание вакцины ушло три месяца. После того, как мы получили штаммы Калифорния 07/2009 и Техас 05/2009 вируса A/H1N1 из Центра по контролю за инфекционной заболеваемостью США (штат Атланта), наши микробиологи приступили к наработке маточного материала. Затем мы подготовили концентрат вируса "свиного гриппа", - пояснил научный консультант цеха противогриппозных вакцин Михаил Пушкарев.

В основе производства была применена уже известная технология по созданию сезонной вакцины против гриппа. В ближайшее время экспериментальные серии вакцины будут отправлены на контроль в Москву, где пройдут испытания на волонтерах.

Вакцина будет выпущена в ампулах для инъекций. Пока не прошли клинические испытания, специалисты затрудняются говорить о возрастном диапазоне применения препарата. Предполагается, что иммунитет вакцинированного человека будет устойчив к вирусу гриппа A/H1N1 в течение года.

По оценкам экспертов, стоимость препарата будет на уровне цены сезонной вакцины. Сейчас предприятие занято производством сезонной вакцины. Ее в этом году по госзаказу выпустят в количестве более 20 миллионов доз.

Число заболевших вирусом гриппа A/H1N1 в мире превысило 212 тысяч, включая 1,717 тысячи случаев с летальным исходом. В Республике Башкортостан зарегистрирован один лабораторно подтвержденный случай заболевания, завезенный из Турции.

Britain says swine flu vaccination to start in October

Reuters, 14 August 2009, 1:44 AM GMT+8
https://www.reuters.com/article/idUSTRE57C490/

London (Reuters) **-** Britain's swine flu vaccination program is to start in October for at-risk groups, Chief Medical Officer Liam Donaldson said on Thursday, with most vaccines coming from drugs firm GlaxoSmithKline.

A first batch of 300,000 vaccines will arrive this month with 54.6 million expected by December, Donaldson said, adding that exact supply levels would depend on the manufacturers.

"We are getting a lower supply from Baxter than we had envisaged so the majority of our vaccines will come from Glaxo," Donaldson told reporters.

Earlier this month, the World Health Organization said it expected the first vaccines to combat H1N1 flu to be ready for use in some countries from September.

Donaldson said the treatments would need to be approved by European medical regulators before vaccinations begin. – "In October we expect, provided the license is granted, to be able to give the first shots of vaccine," he said.

The pace of new H1N1 infections in Britain has eased in recent weeks, with doctor consultations for flu-like illness falling by 34 percent last week.

The majority of cases have proven to be mild and the government plans to slash the number of flu call center staff from around 1,600 to less than 600 by August 23 because of the sharp drop in suspected infections.

But health experts expect another surge later in the year.

"We have seen an increase in the proportion of deaths among previously healthy people," Donaldson said, adding that five of the eight new deaths in England over the last week were of otherwise healthy people.

"It is causing more deaths in healthy people than seasonal flu," he said.

Fears the strain could become resistant to anti-viral drug Tamiflu have underscored the need to get vaccines to market quickly.

The government plans to immunize about 11 million people seen as most at risk first because it does not expect to have enough doses for the whole population before winter.

The first to be immunized will include about 5 million people aged over six months in current seasonal flu risk groups, all pregnant women, contacts of people with compromised immune systems, and about 2 million health and social care workers.

Healthy people over 65 will not be prioritized because they appear to have some natural immunity to the virus, the Department of Health said.

CBSNEWS

Jennifer Ashton

Weighing Possible H1N1 Vaccine Risks
Dr. Jennifer Ashton on both Sides of Flu Vaccine Coin

CBS News, 17 August 2009
https://web.archive.org/web/20091027125606/http://www.cbsnews.com/stories/2009/08/17/earlyshow/health/main5246940.shtml

(CBS) Many are concerned about whether a H1N1 vaccine will be safe. But now reports are out that a swine flu vaccine could cause GBS or Guillian-Barre Syndrome, a brain disorder.

CBS News medical correspondent **Dr. Jennifer Ashton** explained on **"The Early Show"** Monday the risk of GBS is very low – one in every million vaccinations.

Ashton explained GBS is a rare, neurologic disorder that has elements of an auto-immune condition in that some trigger (usually an infection or rarely a vaccination against an infection) results in a progressive weakening of nerves. GBS starts in the legs and works its way up the body. Estimates are that it may occur one time out of 100,000 or one million vaccine doses. In most cases, Ashton said, patients recover approximately four weeks from the first symptoms, and 80 percent of people have a complete recovery. Some however, can die from GBS; the death rate is quoted as 2 to 3 people in 100.

And some did die from GBS in 1976 when an outbreak of swine flu at Fort Dix, N.J. prompted widespread vaccine use after one soldier died from influenza. As the flu spread through Fort Dix, it was discovered that there was the regular type of influenza, but also the swine flu. Some scientists thought it was an indication of a return of the deadly flu from 1918 that killed 50 million worldwide. They quickly developed a vaccine, but the epidemic they were fearing never happened.

However, according to Ashton, it was never determined that what happened in 1976 was caused by the vaccine. Forty million Americans were vaccinated, and 500 cases of GBS were reported with 25 deaths.

"This is actually less than – or at most equal to – the expected rate of this disease in the general population," Ashton told CBS News. "It is a difficult determination to make with 100 percent certainty, but for the people who were affected, and who thought it was due to the vaccine, obviously it was devastating."

But should you get the vaccine for H1N1 when it is scheduled for released in October?

Ashton said it should be a personal decision based up risk versus benefit.

"If you are at high-risk for serious complications of influenza, then if many people get H1N1, your risk of getting sick is probably greater than your risk of having a rare side effect. And the possible benefit may be life-saving for some people. You have to weigh the risks of getting influenza, and the risk of possibly dying from it."

The risk of death from H1N1, Ashton said, is roughly 1 in 1000 people. She said you should weigh that risk against getting vaccinate, which, however safe the vaccine may be, the risk is never zero.

"People need to make those difficult decisions for themselves with good education and information from reputable sources," Ashton said. "I respect both decisions. Ultimately it's up to the patient."

Sinovac says one-shot swine flu vaccine effective

Reuters, 18 August 2009, 11:10 PM GMT+8
https://www.reuters.com/article/flu-sinovac-idUSLI544899200908l8/

London, Aug 18 (Reuters) – An H1N1 swine flu vaccine developed by China's Sinovac Biotech is effective after just one shot, its developer said on Tuesday.

The news boosted shares in the Chinese vaccine company by 10 percent in U.S. trading.

Until now, experts have predicted that two shots will be needed to provide swine flu immunity. But Sinovac, which is the first company worldwide to complete clinical trials for an H1N1 vaccine, said a single dose of its vaccine proved sufficient.

Leading flu vaccine makers including Sanofi-Aventis, GlaxoSmithKline, Novartis, Baxter, CSL and Solvay are racing to develop a vaccine against swine flu.

The H1N1 flu outbreak, which was declared a pandemic on June 11, has spread around the world and could eventually affect 2 billion people, according to the World Health Organisation.

Officials are concerned that supplies of vaccine will prove tight, but an ability to vaccinate people once instead of twice would stretch stocks substantially.

Sinovac said immunogenicity after one dose of its vaccine had "reached the international criteria for vaccines". There were no signs of severe adverse reactions, it added.

Its clinical trials were initiated in Beijing in July and inoculation was completed on Aug. 15, with a total of 1,614 participants over three years receiving the vaccine.

Regulators around the world are expected to start approving swine flu vaccines next month as more clinical trial results come in, allowing governments to start mass vaccination programmes from September, according to the WHO.

Medical experts say vaccines need to available quickly and in large quantities to have the greatest impact.

Vaccines arrived too late in the 1957 and 1968 flu pandemics to be of much use and flu vaccines had not been developed in the 1918 "Spanish flu" pandemic which killed an estimated 50 million.

TELEGRAM & GAZETTE

Logjams delay swine flu vaccine

Telegram & Gazette, The Associated Press, 18 August 2009, 8:35 pm ET
https://www.telegram.com/story/news/state/2009/08/19/logjams-delay-swine-flu-vaccine/51895201007/

Faced with an unexpected delay, health officials are trying to counter new problems with swine flu vaccine production, including a logjam at factories that put the precious liquid into syringes.

The newest calculations show the nation won't have the long-promised 120 million doses ready to dispense by Oct. 15, but just 45 million instead.

It appears to be more of a delay than a shortage: More are expected to arrive rapidly, about 20 million doses shipped every week, according to the latest estimates by the Department of Health and Human Services.

"Hopefully there are ways to bring that number up," Dr. Robin Robinson, the department's chief of vaccine procurement, said today.

"We're trying to bring on more manufacturing" for the final packaging step, he said, such as having companies that finish first share their facilities with stragglers.

Swine flu vaccinations still are planned for mid-October, and Robinson noted that 45 million doses means a lot of people inoculated. Add in the weekly deliveries, and there should be 85 million doses on hand by October's end, and the full 195 million the government has ordered by December, the long-set date for final delivery.

But he acknowledged that if there are early outbreaks in September and October, there could be higher-than-anticipated demand for the swine flu vaccine.

"As we've all along said, if things can go wrong they will," Robinson said.

Manufacturers around the world revealed in July that they were having serious problems brewing vaccine. The chief ingredient is grown in eggs, and companies were getting far fewer doses per egg than they usually do for regular winter flu vaccine.

Health authorities have delivered new "seed strains" of the virus to manufacturers to help with that problem, Robinson said.

In addition to the packaging logjam, other factors are adding to the delay, including:

– One manufacturer, Sanofi-Pasteur, took longer than expected to finish brewing the regular winter flu vaccine, delaying the swine flu work, Robinson said. "We knew there were problems," but only recently the extent of them, he said.

– Another supplier, Australia's CSL, recently notified the U.S. that its shipments would arrive later than promised because it first must provide batches to its home country, where the flu season is winding down. Although the U.S. signed a contract with CSL first, "there was always the possibility they could do that," Robinson said. "Our laws can do the same thing. We don't, but we could."

– And it took health authorities longer than anticipated to develop the tests, called reagents, required to ensure doses are at the proper strength before they're cleared for use.

Swine flu vaccine encounters delays

The Eagle, Associated Press, 19 August 2009
https://theeagle.com/news/business/swine-flu-vaccine-encounters-delays/article_b2185c7d-e28b-5c2f-bb67-d589e7618d58.html

Washington - Faced with an unexpected delay, health officials are trying to counter new problems with swine flu vaccine production, including a logjam at factories that put the precious liquid into syringes.

The newest calculations show that the nation won't have the long-promised 120 million doses ready to dispense by Oct. 15, but just 45 million. It appears to be more of a delay than a shortage: More are expected to arrive rapidly, about 20 million doses shipped every week, according to the latest estimates by the Department of Health and Human Services.

"Hopefully there are ways to bring that number up," Dr. Robin Robinson, the department's chief of vaccine procurement, said Tuesday.

"We're trying to bring on more manufacturing" for the final packaging step, he said, such as having companies that finish first share their facilities with stragglers.

Swine flu vaccinations still are planned for mid-October, and Robinson noted that 45 million doses means a lot of people inoculated. Add in the weekly deliveries, and there should be 85 million doses on hand by October's end, and the full 195 million the government has ordered by December, the long-set date for final delivery.

But he acknowledged that if there are early outbreaks in September and October, there could be higher-than-anticipated demand for the swine flu vaccine.

"As we've all along said, if things can go wrong they will," Robinson said.

Manufacturers around the world revealed in July that they were having serious problems brewing vaccine. The chief ingredient is grown in eggs, and companies were getting far fewer doses per egg than they usually do for regular winter flu vaccine.

Health authorities have delivered new "seed strains" of the virus to manufacturers to help with that problem, Robinson said.

Russia to begin testing of vaccine from swine flu in early September

Hindustan Times // Itar-Tass, St Petersburg, 20 August 2009, 10:17 AM IST
https://www.hindustantimes.com/world/russia-to-begin-testing-of-vaccine-from-swine-flu-in-early-sep/story-IDzlwBBBwroj9TN7CXpJxK.html

The Flu Research Institute has handed over experimental vaccines from the A/H1N1/ virus to companies for production of pilot batches, head of the National Flu Centre of the WHO in St Petersburg, Oleg Kiselev, said.

The Flu Research Institute has handed over experimental vaccines from the A/H1N1/ virus to companies for production of pilot batches, head of the National Flu Centre of the WHO in St. Petersburg, Oleg Kiselev, said. He said this was necessary for further clinical tests.

The vaccines are scheduled to be tested on volunteers after September 7. The experiment may last a month, Kiselev said. The Flu Research Institute said pilot batches of vaccines would be made in St Petersburg, Irkutsk and Ufa. "The schedule of creating the vaccine from the new flu is under systemic control of the Ministry of Health and Social Development," Kiselev added.

Earlier Russia's chief Sanitary Inspector Gennady Onishchenko had said that 40 million doses of the vaccine from the new flu would be made in the country in 2009. Confirming the news first Vice Prime Minister Viktor Zubkov said, "Funding for the production of the vaccine has been secured, and the enterprises to be involved in this work are ready."

He also added that all work on the vaccine is proceeding as scheduled and testing should be completed at the end of August so that commercial production of the vaccine and its supply to medical institutions could begin in November. The government has provided 340 million roubles for the prevention of the spread of the new flu.

Most of that sum has been earmarked for the creation of the vaccine. A total of 180 A/H1N1/ cases have been registered in Russia till date.

H1N1 Vaccine Patent filed (2007) long before the Swine Flu virus was spread!

CAFR1.com, 20 August 2009
https://web.archive.org/web/20091216044011/http://cafr1.com/H1N1.html
https://patentimages.storage.googleapis.com/37/d1/04/0ba7f9ba430332/US20130287811A1.pdf

Pay special attention to the strains of the H1N1 noted in the 2007 filing. Coming to your hometown soon!

The following is my reply to John Perna per a US Patent Application filed, with one aspect of the patent being for the Swine Flu virus vaccine (H1N1). The patent application was filed long before the Mexican Swine Flu supposedly came forward as a new strain of virus coming out of a "Pig Farm" in Mexico.

In John's post copied in part below my reply, he thought the patent application for the H1N1 vaccine was from 2008 shortly before the swine flu broke out in Mexico.

I am familiar with patents, so I took a look at the US Patent and Trademark site to verify what he was bringing forward was correct and found he was in error. The original application was actually filed in 2007. Long before the virus was staged as an outbreak of "a new viral strain" in Mexico.

As far as I am concerned, this now verified information puts the last nail in the coffin for the immediate suspension of all forms of "civil" government in this country for reorganization under limited purview and then reinstatement. And I hope, no I pray that when done in end result, they axe 85% or more of the attorneys from the system. That is 90% of the solution right there.

Here is the US Patent office link to see that patent

Some flu shot shipments will be delayed

Medical Economics, 21 August 2019
https://www.medicaleconomics.com/view/some-flu-shot-shipments-will-be-delayed

Shipments will be delayed for some flu vaccines, but the delays aren't expected to create any overall shortages.

The delayed shipments apply to flu vaccines produced by Sanofi Pasteur, which sent letters to healthcare providers announcing the issue in late June. The delay will push out the starting point to start flu vaccinations for the year, but vaccines should still arrive in plenty of time to keep patients protected for the flu season, according to company officials.

"We are still on track to produce approximately 70 million doses of seasonal vaccine to support nationwide immunization campaigns," said Michael Szumera, head of U.S. communications for Sanofi Pasteur.

The company anticipates roughly a one-month delay in the first shipment of the vaccine, with shipments beginning in mid-August. All shipments should be completed by the end of November, Szumera said. Patients are generally recommended to be vaccinated for the flu by the end of October, as vaccines take two weeks to offer protection, according to the Centers for Disease Control and Prevention (CDC). The flu season typically peaks between December and February.

The delay was caused by the World Health Organization (WHO) postponing its selection of the influenza A (H3N2) strain to be included in the vaccine for the Northern Hemisphere by one month after observing antigenic drift in the circulating strain, Szumera said.

"This allowed health authorities to collect additional data to improve the match of the vaccine strain to the A (H3N2) strain anticipated to circulate during the 2019-2020 season," he said. "Manufacturing could not begin until the selection was made by WHO and confirmed by the U.S. Food and Drug Administration."

The delay will affect all three Sanofi Pasteur vaccines-Fluzone Quadrivalent, Fluzone High-Dose, and Flublok Quadrivalent. Sanofi Pasteur's flu vaccines make up about 40 percent of the U.S. flu vaccine supply, according to data from the Centers for Disease Control and Prevention (CDC).

"As the single largest provider of flu vaccine to the United States, we support this decision and are committed to delivering millions of flu vaccine doses for the upcoming season," Szumera said.

Other flu vaccine manufacturers have not announced delays, but AstraZeneca has warned that FluMist Quadrivalent supplies will be limited this year due to manufacturing constraints.

Clinicians who have questions about their vaccine orders should contact their distributor, and Szumera said questions specific to the Sanofi delay can call (800) 822-2463.

Swine Flu Campaign Waits on Vaccine

Washington Post, 23 August 2009

3rd page: https://www.washingtonpost.com/wp-dyn/content/article/2009/08/22/AR2009082202337_3.html?hpid=topnews&sid=ST2009082300274

Government health officials are mobilizing to launch a massive swine flu vaccination campaign this fall that is unprecedented in its scope – and in the potential for complications.

The campaign aims to vaccinate at least half the country's population within months. Although more people have been inoculated against diseases such as smallpox and polio over a period of years, the United States has never tried to immunize so many so quickly.

But even as scientists rush to test the vaccine to ensure it is safe and effective, the campaign is lagging. Officials say only about a third as much vaccine as they had been expecting by mid-October is likely to arrive by then, when a new wave of infections could be peaking.

Among the unknowns: how many shots people will need, what the correct dosage should be, and how to avoid confusing the public with an overlapping effort to combat the regular seasonal flu.

To prepare, more than 2,800 local health departments have begun recruiting pediatricians, obstetricians, nurses, pharmacists, paramedics and even dentists, along with a small army of volunteers from churches and other groups. They are devising strategies to reach children, teenagers, pregnant women and young and middle-aged adults in inner cities, suburban enclaves and the countryside.

"This is potentially the largest mass-vaccination program in human history," said Howard Markel, a professor of medical history at the University of Michigan who is advising the Centers for Disease Control and Prevention as it spearheads the effort.

Public health officials describe the effort as crucial to defend against the second wave of the Northern Hemisphere's first influenza pandemic in 41 years.

As schools reopen, the number of cases could jump sharply within weeks, sparking a second wave potentially far larger than the outbreak last spring. Although the swine flu appears no more dangerous than the typical seasonal flu, the new virus – known as H1N1 – is likely to infect many more people because most have no immunity against it.

The vaccine effort carries political risks for the Obama administration. "If the outbreak fizzles, they will be susceptible to being criticized for spending billions of dollars," said Harvey V. Fineberg, president of the National Academy of Sciences' Institute of Medicine, which advises Congress about medical issues. "On the other hand, if this outbreak is early and severe and there isn't enough vaccine, they'll be criticized for under-preparation."

Officials stress that they are proceeding cautiously. A final decision to move forward will not be made until they get the results of clinical trials – testing to determine safety and dosing – and assess the virus's threat. But officials are confident the vaccine will pass muster and expect a campaign will be launched as soon as manufacturers deliver the first vials.

"There's little doubt we're going to vaccinate people," said Anthony S. Fauci of the National Institute of Allergy and Infectious Diseases, who is leading the government's testing of the vaccine. "Who and when and exactly how – we have to figure out."

The campaign is haunted by memories of the government's ill-fated 1976 effort to vaccinate against swine flu. The epidemic fizzled, but the vaccine was given to 40 million people and blamed for causing a rare paralyzing disorder known as Guillain-Barré Syndrome.

Another wild card will be whether the vaccine will be delivered with an "adjuvant" to boost its effectiveness or stretch limited supplies into more doses. Adjuvants have been used in Europe, but the Food and Drug Administration has not authorized their use in the United States.

"This is an overreaction," said Barbara Loe Fisher of the National Vaccine Information Center, which opposes many vaccine policies. "There is no national security threat here. Why are we operating like this? This is not polio. This is not smallpox."

Fears and misinformation about the vaccine are circulating, including inaccurate claims that it will be mandatory.

"I'm very concerned about the dangers of vaccines," said Janice Smith, 58, of Misawaka, Ind., who attended a public hearing Aug. 15, one of a series of meetings the CDC has sponsored to gauge public sentiment about the vaccine.

Authorities are adamant that vaccination will be voluntary, and they say there is no reason to think the vaccine will be any less safe than the usual flu vaccine. An adjuvant will be used only if necessary and proven safe, they say.

To address concerns of pregnant women and parents with young children, some vaccine is being produced without a mercury additive. And because the short-term studies can identify only common, immediate side effects, the CDC will step up monitoring for rarer, serious complications such as Guillain-Barré.

"We're putting into place systems that are as good as we can have to identify problems quickly if they do occur," CDC Director Thomas R. Frieden said.

On Friday, officials reported that no "red flags regarding safety" had emerged in the clinical trials. "We are continuing oversight on the quality and safety of the vaccine being produced, and the production process itself," said Jesse Goodman of the FDA. "That's going well so far, but our oversight is continuing."

In the meantime, local officials are drafting plans tailored to their communities. The shots in the arms and squirts up the nose will happen in schools, medical offices, hospitals, public health clinics, workplaces, drug stores and at mass vaccination events, possibly including drive-through clinics in parking lots where people would stick their arms out their car windows for a stab.

"It is clearly what we would call an all hands on deck," said James Blumenstock of the Association of State and Territorial Health Officials. "We're not starting from scratch, but we also don't have everything on the shelf that we can just pull off and put in place. It's a full-court press in moving forward to have everything in place when we're ready to go."

In Maryland, officials estimate that 2.9 million people fall into the priority groups for the vaccine; Virginia estimates the number at 2.5 million and the District at 225,000. The national total is about 159 million people.

Public health departments "have suffered from decades of neglect and are now facing a fiscal crisis in many places where they have had to lay staff off, or furlough staff or freeze hiring," Frieden said. "So H1N1 has not come at a particularly good time."

Setting priorities for delivering the vaccines will bring other complications. The elderly, usually first in line for flu shots, will not be this time because they seem more resistant to the virus. But they remain a top priority for the seasonal shots.

Schools considering giving shots to children are making plans to get permission from parents and have to determine how best to line up anxious, rambunctious students.

Everyone who gets a swine flu shot may need a booster several weeks later, potentially causing mix-ups about who got which shot when.

But Frieden and other outside observers expressed confidence that the program would be safe and successful.

The federal government has spent close to $2 billion to buy up to 195 million doses of vaccine and adjuvant, including the standard shots and the newer FluMist nasal spray vaccine made by MedImmune of Gaithersburg.

The government is prepared to buy enough to vaccinate every person – 600 million doses all together – if the pandemic or demand warrants it. That could increase the cost to $5 billion for the vaccine alone. It would cost at least $9 billion to administer the vaccine to the entire population, according to the Association of State and Territorial Health Officials.

Although five companies are racing to produce as much vaccine as possible, the first batches are not expected for two months, in part because the virus grew at about half the projected rate. Production appears to be increasing, but the first 45 million to 52 million doses – about a third of what officials were anticipating – won't be ready until mid-October, with about 20 million doses a week expected after that to continue the campaign through the winter.

Experts are uncertain whether they will face a shortage of vaccine because of high demand or will have plenty of vaccine but little interest.

"People's enthusiasm will depend largely on what they see happening around them," Fauci said. "If we get into the fall season and we don't see an explosion of cases, people will be less enthusiastic. If they see a lot of young people and kids getting sick, people will be very enthusiastic about getting vaccinated."

The CDC is formulating a $4.8 million multimedia campaign to encourage people to get vaccinated and help alleviate concerns and confusion, including radio and television public service announcements, print ads, and messages delivered via Twitter, RSS feeds and video podcasts on YouTube.

Although the vaccine will be free, providers could charge about $15 to administer it – a fee that will be covered by Medicare and many health insurance plans.

Experts also worry the swine flu will divert attention from the seasonal flu, which can cause serious illness. Officials will launch the seasonal flu vaccine campaign Sept. 10 – about a month early in the hopes of vaccinating as many people as possible before the swine flu campaign. The more people who get both vaccines, the less likely the swine flu virus will mingle with one of the others to produce a more dangerous mutant.

"We really don't want those ugly viruses mixing together," said Kim Elliott of the Trust for America's Health, a private nonprofit research and advocacy group.

Behind the Unproven H1N1 Flu Vaccine

Time, CNN, 26 August 2009
https://web.archive.org/web/20090827163439/http://www.time.com/time/health/article/0,8599,1918743,00.html

Public health officials have been warning for some time that nothing about the flu is predictable. But here's something that is: When it comes to a new strain of the flu like H1N1, which has already stoked global fears of a massive pandemic, there's almost certain to be some overreaction. That's what happened this week when the public was hit with a double-play of scary news: A new estimate showed that that up to 90,000 Americans could die of H1N1 in the upcoming season; and a simultaneous report that the government was taking some unprecedented steps to get a vaccine ready in time. But the fatality numbers are more complicated – and less alarming – than they seem; and the vaccine report is less a reason for alarm than a sign of smart epidemiological planning.

What sparked the reports about insufficient testing of the new vaccine was a statement by Dr. Thomas Frieden, director of the Centers for Disease Control, confirming that the government has given flu vaccine manufacturers a green light to begin bottling up still-experimental shots and readying them for shipment, even before the final results from the ongoing tests on the vaccine's safety and effectiveness are completed.

It's an unusual step, but one that was also recommended by the President's Council of Advisers on Science and Technology (PCAST) in a report released the same day. By initiating the so-called "fill and finish" step of vaccine production, manufacturers can be prepared to ship vials as quickly as possible in mid-October, once testing confirms that the shots are safe and effective at producing immunity against H1N1. "The recommendation was to proceed with filling and finishing even before dosage information is available," said Frieden. "That step has been taken."

That doesn't mean, however, that anyone will get an unproven vaccine. The vials will stay right where they are until the testing is completed – and for now, those trials are going well. Secretary of Health and Human Services Kathleen Sebelius, also speaking at the workshop, noted that "So far there are no red flags. I think we are on target for mid-October to have the vaccine coming off the production lines."

The reason for the wait is biological. The first volunteers to test the new vaccine were inoculated in August, and because most people will not have any existing immunity to H1N1, it will require two shots, spaced three weeks apart, to educate the immune system to recognize H1N1, and another six to eight weeks after that to generate true immunity to the virus. That's when scientists will know if the vaccine provided enough protection to allow the bottled inoculations to be shipped. After decades of making flu vaccines, the scientists are sure they know what they're doing. Indeed, had the pandemic begun earlier, in December or even January – when the World Health Organization made its determination of which flu strains to include in the routine seasonal flu vaccine – instead of April, then H1N1 might have simply been included as part of the 2009 shots.

Still, the decision to approve the fill and finish steps underscores how unusual H1N1 is, and highlights the fact that the upcoming flu season may yet hold surprises. In its report, PCAST also released projections of how severe the pandemic could get: up to 120 million people coughing, sneezing, feverish and otherwise sick with the symptoms of flu, 90,000 people potentially dead from the illness, and half to 100% of beds in intensive care units of hospitals in hard-hit regions filled with flu patients.

But even those alarming numbers require some perspective. The figures, says PCAST member Dr. Harold Varmus, president of Memorial Sloan Kettering Cancer Center in New York and former director of the National Institutes of Health, were generated using data from previous flu pandemics – from 1918, 1957 and 1968 – along with the latest data from last spring's outbreaks of H1N1 around the world. Those stats, say officials at the Centers for Disease Control, were then run through models used in the government's 2005 pandemic preparedness efforts that began in the wake of bird flu cases of H5N1 that arose in Asia.

That's a lot of moving statistical parts, and when it comes to an ongoing pandemic such as the current one with H1N1, it's especially difficult to get reliable data on how many people are infected, how effectively the virus is moving from person to person, and how much disease it can cause. Death rates from H1N1 are particularly challenging, since making reliable projections requires comparing the total number of people infected with H1N1, as confirmed by a lab test, to those who have died from the disease. At the moment, officials don't know how many people have actually been infected with the virus; they can only count people who are sick enough to see a doctor or come to a hospital. For every person who shows up in a hospital, however, there are likely hundreds or thousands more infected with H1N1 who never see a health care professional, because they don't get very ill. That means there's a lot of educated guesswork at play.

By no measure, however, were the new numbers reassuring – and that was the point. While the report's authors, which include some of the country's sharpest minds from science, medicine and engineering, stress that the forecast is not predictive of what could actually occur in coming months, it was intended to remind everyone how devastating a flu pandemic can be.

"There are some people taking the figures too literally," says Varmus. "But it's a wake-up call. The public wants to be aware that while these numbers are not predictive, they are certainly well within the realm of possibility."

Such predictions are also a way for public health officials to get a handle on how infectious a new influenza like H1N1 might be, how it spreads, and how quickly. That helps them know how much vaccine might be needed, how to distribute it, and when to expect a surge in demand for flu treatments, including antiviral drugs such as Tamiflu and Relenza. It can also help predict when hospitals might become overwhelmed by flu cases, and prepare them to patch up already strained health care resources.

"We can't yet predict what proportion of the population will be infected," says Varmus. "But it is very likely that something upward of 50% will be affected. All of us have a responsibility to blunt the epidemic by decreasing the spread of virus. If people understand that they can mitigate the epidemic by washing their hands and staying home when they are sick, it means the peak of disease will occur later, when there is more vaccine available." That could also help to keep the impact of H1N1 – on the health care system, on families and on the economy in the form of fewer sick days – to a minimum.

CHINADAILY 中国日报网 .COM.CN

Mexico to buy A/H1N1 flu vaccine from China (Xinhua)

China Daily, 27 August 2009, 14:31
https://global.chinadaily.com.cn/business/2009-08/27/content_8624357.htm

The Mexican government will buy 10 million doses of A/H1N1 flu vaccine from China, bringing its total stockpile to 30 million doses, Health Minister Jose Angel Cordova Villalobos said Wednesday.

A total of 20 million doses have been commissioned from European laboratories ahead of Mexico's winter season, when the infection rate is expected to increase sharply, he said.

Cordova said the Chinese vaccine will cost about 40 percent less than its European equivalents and is easier to apply.

Mexico has reported 20,860 confirmed A/H1N1 flu cases, including 179 deaths, according to a report published Tuesday.

During his official visit to China last week, Cordova met with his Chinese counterpart and attended a seminar on fighting A/H1N1 flu.

The Sydney Morning Herald

Britain, France get first batches of swine flu vaccine

The Sunday Morning Herald, 28 August 2009, 7:11 am
https://www.smh.com.au/world/britain-france-get-first-batches-of-swine-flu-vaccine-20090828-f1i2.html

Britain and **France** have received their first batches of swine flu vaccine as governments begin to arm themselves against a widely expected second wave of the pandemic in the northern winter.

The World Health Organisation has been warning governments for months to brace for a resurgence of the A(H1N1) virus when the cold season hits the northern hemisphere.

The doses to combat the pandemic arrived as millions of children prepared to return to school in the next two weeks, with concerns that the virus could spread easily between classrooms.

In **South Korea**, the education ministry announced that all primary and secondary schoolchildren will have their temperature checked daily to combat the spread of H1N1 when they return to school next week.

The recent discovery of an outbreak in Chilean turkey farms also raised concerns that swine flu could combine with avian influenza and become a more dangerous virus, a UN agency said. It is the first case of H1N1 among birds.

British and French health officials said the H1N1 vaccine should win licensing approval for distribution in their countries by October.

Britain's Department of Health said it received a first batch of 100,000 doses of swine flu vaccine, while France only announced the arrival of a "limited quantity" of shots.

A British health department spokeswoman said the vaccine was delivered by US pharmaceutical company Baxter and that it could be approved for public distribution by early October "if everything is fairly straightforward".

Once it is fully licensed the vaccine will initially be used on at-risk groups, such as people with asthma and diabetes, officials said.

England's Chief Medical Officer Liam Donaldson said doctors he had spoken to want the vaccine as soon as possible before winter arrives.

Britain is the European country hardest hit by the virus, which emerged in Mexico in April before escalating into a global pandemic. So far 66 people with the virus have died in Britain.

Donaldson stressed that the vast majority of cases produce relatively mild symptoms, while adding: "It still remains the case that this disease is not a killer but it can kill."

French Health Minister Roselyne Bachelot refused to disclose the type of vaccine or the number of doses her country had received, citing "security reasons".

France has reserved 94 million doses of vaccine from four pharmaceutical companies and expects to have several million doses by mid-October when the vaccines are set to win market approval, Bachelot said.

The French government called on regional authorities to have their free vaccination plans ready to activate on September 28.

Up until now, France had included only laboratory-confirmed cases of the disease, recording a total of 1,223 cases since the start of the epidemic.

But based on the number of visits to doctors across France, Bachelot said the number of new infections was now estimated at 3,000 per week.

John Oxford, professor of virology at Britain's St Bartholomew's and the Royal London Hospital, said France could be heading for a tough winter.

"Some countries in Europe will have it worse than others. France, for example, will have it worse than England. A lot of people have been infected in England and they are not going to be infected all over again," he told AFP.

The UN Food and Agriculture Organisation also expressed concern after the discovery of swine flu in Chilean turkeys that the virus could become more potent if it manages to mix with bird flu.

"The current H1N1 virus strain is a mixture of human, pig and bird genes and has proved to be very contagious but no more deadly than common seasonal flu viruses," the Rome-based agency said in a statement.

"However it could theoretically become more dangerous if it adds virulence by combining with H5N1, commonly known as avian flu, which is far more deadly but harder to pass along among humans," it said.

Baxter Files H1N1 Swine Flu Vaccine Patent a Year Ahead of Outbreak

Fight Back, August 2009
https://web.archive.org/web/20090904101539/http://www.fightbackh1n1.com/2009/08/proof-h1n1-is-bioweapon-as-baxter-files.html

Proof H1N1 is Bioweapon as Baxter Files H1N1 Swine Flu vaccine Patent a year ahead of Outbreak.

New York: Baxter had patented vaccines for viruses that even don't exist a year back. This Clearly shows that the pandemic virus was not an act of nature.

The Primary Motive behind this alleged criminal activity is also the primary cause of most murders in the world today, and that motivation is simply: BIG MONEY. Billions of Dollars of windfall profits from government contracts worldwide, as a matter of fact.

And yes the the Swine Flu virus H1N1 is listed "with many others" as copied from the Patent Application here at: [0056] "A vaccine can be used e.g. for an injection as a prophylactic means against a virus associated disease. In particular preferred embodiments the composition or vaccine comprises more than one antigen, e.g. 2, 3, 4, 5, 6, 7 or 8, in particular of different virus strains, subtypes or types such as influenza A and influenza B, in particular selected from of one or more of the human H1N1, H2N2, H3N2, H5N1, H7N7, H1N2, H9N2, H7N2, H7N3, H10N7 subtypes, of the pig flu H1N1, H1N2, H3N1 and H3N2 subtypes, of the dog or horse flu H7N7, H3N8 subtypes or of the avian H5N1, H7N2, H1N7, H7N3, H13N6, H5N9, H11N6, H3N8, H9N2, H5N2, H4N8, H10N7, H2N2, H8N4, H14N5, H6N5, H12N5 subtypes. "

Our additional concern is all the others virus vaccines listed but not yet promoted yet, get my point!

You may want to get this into a few specialists hands for comment immediately.

The following link is the most important. It shows that the original application was filed in 08/28/2007. - https://patents.google.com/patent/US20090060950A1/en

Start off from here http://portal.uspto.gov/external/portal/pair and when you get to the search page make sure "application number" is checked off and in the search field put in the application number of: 60/966,724

When it opens the page click on the tab "Image File Wrapper" then select "Specifications" and go to page "13" of the specifications. Here you will see the virus references to the viruses as noted above and it did so on "08/28/07" long before the virus was promoted as a "New and Deadly Strain" morphed out of a pig farm in Mexico.

NBC NEWS

China set to approve 1-dose swine flu shots

NBC News / The Associated Press, 2 September 2009, 10:52 PM +08
https://www.nbcnews.com/id/wbna32656525

China will soon approve domestically developed swine flu vaccines that manufacturers say can protect people against the virus with only one dose, an encouraging development for health officials racing to prepare for an expected spike in cases this winter.

The answer may be near to a crucial question about vaccine for the advancing swine flu – one shot or two?

Chinese officials say they are about to approve vaccines that prevent the new flu in a single dose.

If they're right, it would be good news. Many health researchers fear it will take two shots to protect people, vastly complicating efforts to stem the spread of the illness.

The World Health Organization says it is encouraged after reviewing the test details from one of the two Chinese vaccines. However, experts said more results are needed from other vaccine makers to determine if one dose would be potent enough.

Australia-based CSL should know within days whether one dose of its vaccine, administered to volunteers in that country in late July, was enough. CSL to date has been mum.

In about two weeks, the U.S. expects to announce initial test results from its vaccine, which is the same type as one of the Chinese versions, said Dr. Anthony Fauci of the U.S. National Institutes of Health.

"From what I've seen and heard of the data, it looks encouraging," Fauci said of the clinical trials of the Chinese vaccine from Sinovac Biotech Ltd. "This is very good news. Let's hope the material that we're using has similar results."

Dr. Tom Frieden, director of the federal Centers for Disease Control and Prevention, said his agency would need to review data suggesting that one dose of H1N1 vaccine will be enough and suggested that it might vary by population.

"It's very likely that at least for kids, two doses are going to be required," Frieden said.

Most experts, however, are optimistic at the prospect of a success of a single shot.

"Everybody is desperately hoping that one (shot) will do because then that's much easier to administer," said Jodie McVernon, a vaccine expert at the University of Melbourne who is involved in Australian trials of swine flu vaccines for young children. She had not seen the Chinese trial results.

However, James McGlothlin, a member of Purdue University's pandemic planning committee, was cautious about the Chinese report.

"They've got some very good scientists over there, but anything that sounds too good to be true ought to be scrutinized," he said in a telephone interview.

"I'd like to look at some of the clinical trials," that led to the one-dose conclusion, he said. "In China, the rules are a little bit different in terms of human subjects," and it's not clear what safety factors were in place, he said.

China's State Food and Drug Administration said on its Web site it will make a decision this week on approving the two vaccines, which completed testing last month and passed reviews by panels of about 40 experts. Four other vaccines are being reviewed, it said.

Government-backed vaccine makers Sinovac and Hualan Biological Engineering Inc. said their studies show one shot of vaccine is effective on people ages 3 to 60. More than 3,000 people participated in the trials.

Sinovac says it has the capacity to produce up to 30 million doses of swine flu vaccine in a year, while Hualan said it can make 160 million doses.

Stockpiling vaccines is China's latest move in its aggressive approach to contain the spread of swine flu in the country of 1.3 billion people and relatively limited medical resources. It has quarantined travelers on suspicion of contact with infected people and ordered schools to test students' temperatures.

The Health Ministry says around 3,700 cases of swine flu have been confirmed on the mainland – none fatal.

China aims to have enough swine flu vaccine for 5 percent of the public by the end of the year, and although health officials have not released detailed vaccination plans, they have said health workers, public service workers and students are priority groups.

Should China export vaccines, however, quality concerns could arise.

Though China is a worldwide manufacturing center for pharmaceuticals, suppliers have been known to substitute cheaper and sometimes lethal ingredients. Tainted cough syrup was linked to several deaths in Central America and blood thinners made with contaminated products are suspected in dozens of deaths in the U.S. in recent years.

Last week, Mexico's health secretary, Jose Angel Cordova, said Mexico is considering buying vaccines from China, which would be more than 40 percent cheaper than other vaccines being offered to the government. But Mexico would want a guarantee that China's vaccine is safe and effective, he said.

The World Health Organization said information provided by Sinovac showed that in studies, the vaccines were tested in three formulations of 15 micrograms per dose, and all gave antibody responses that satisfied regulatory criteria. That vaccine dose is the same amount the U.S. government is testing.

"We have no reason to doubt what Sinovac is reporting," said Melinda Henry, a WHO spokeswoman in Geneva. "Certainly if one dose proves sufficient to produce the desired immune response, this would be very encouraging in terms of augmenting the global supply of vaccine in the near future."

International health experts say swine flu has not been as severe as initially feared. At least 2,185 people have died, but most cases are mild and require no treatment. Worries remain that a rash of new infections could overwhelm hospitals and health authorities, particularly in poorer countries.

White House advisers have estimated that in a worst case scenario, half the U.S. population could become infected and the World Health Organization predicts that within two years nearly one-third of the world's population will have caught it.

CHINADAILY 中国日报网 .COM.CN

Sinovac gets first production license for A/H1N1 flu vaccine (Xinhua)

Chian Daily, 3 September 2009, 15:38
https://global.chinadaily.com.cn/world/2009-09/03/content_8875747.htm

Beijing: China approved Thursday the A/H1N1 flu vaccine produced by domestic pharmaceutical company Sinovac, making it the first to get a production license in the global race.

The State Food and Drug Administration (SFDA) issued the license for Sinovac's vaccine called Panflu.1 on Thursday, after it passed SFDA's experts evaluation on August 31.

Panflu.1 could safely be given to people aged from 3 to 60 years old in a single shot, 15 microgram dose, according to the evaluation report.

Sinovac had the capacity to produce 5 million doses of vaccine before October1, and 20 million to 30 million doses per year, said president Yin Weidong.

Another A/H1N1 flu vaccine, produced by Chinese pharmaceutical company Hualan Biological Engineering Inc.,is also hopeful to be given the country's second approval this week.

Who is making the swine flu vaccine?

Reuters, 3 September 2009, 7:46 PM
https://www.reuters.com/article/us-flu-vaccines-factbox-sb-idINTRE5822NQ20090903

(Reuters) - Pharmaceutical companies are racing to develop a vaccine against swine flu ahead of a possible spread of the virus in the northern hemisphere autumn and winter.

Officials are worried vaccine supplies will prove tight and sales are expected to provide a windfall for the global drugs industry.

Here are details of some companies' progress in making and supplying the vaccine:

GLAXOSMITHKLINE

Glaxo is testing its pandemic H1N1 swine flu vaccine in humans and expects to start giving the results to government agencies in September.

The world's second largest drugmaker said in August it has won orders for H1N1 swine flu vaccine from a further nine governments, taking the total number of doses ordered to 291 million. With more orders still to come, it could be in line for a flu vaccine windfall of more than $3 billion in the next six months or so, according to industry analysts.

SANOFI-AVENTIS

The world leader in flu shots has received major orders from the United States and France for H1N1 flu vaccines and said in July it was in discussion with more than 30 countries about supplies, though it cautioned 2009 sales might not be that large.

An executive said last month Sanofi is "reasonably" comfortable it would be able to honor its contract to supply H1N1 swine flu vaccines to the United States in October. It has a $250 million deal to provide the United States with the swine flu antigen in bulk. Sanofi would also fill France's order of doses between November and early December, as planned.

NOVARTIS

Basel, Switzerland-based Novartis -- whose vaccine gave a strong response even after one dose in a pilot trial -- expects to have a vaccine ready by the end of September or October. It has secured several orders for H1N1 vaccines, though does not expect to see any benefit in its figures until the fourth quarter.

ASTRAZENECA

Astra's MedImmune unit has an initial $90 million order from the U.S. government and has said there is potential for more orders.

MedImmune's vaccine technology, currently only available in the United States, is different from traditional injectable flu shots in that it is a mist sprayed into the nose, where the flu virus usually enters the body.

SINOVAC

China's Sinovac Biotech is the first company worldwide to complete clinical trials for an H1N1 vaccine, which has received approval from Chinese health authorities. Experts have predicted that two shots will be needed to provide swine flu immunity, but Sinovac said a single dose of its vaccine proved sufficient.

CSL

CSL has been in mass production of H1N1 vaccine for several weeks, has completed a first batch of 2 million shots and is producing 1-1.5 million doses per week until it fills all orders.

The Australian group has won a $180 million contract from the United States for H1N1 flu vaccine and an order for 21 million doses for the Australian government, saying in May it expected to book sales of about $250 million from swine flu vaccines in the year to 2010.

BAXTER

Baxter International has completed its first commercial batches of H1N1 vaccine made using a cell culture process designed to be faster than traditional vaccine production methods that use chicken eggs. It has supply contracts with countries including Britain, Ireland and New Zealand, but not the United States, and said in July it could not take on additional orders.

SOLVAY

Solvay said in late July that production of a cell-based H1N1 vaccine for clinical studies would start in August. The Belgian group missed out in June on a Dutch government contract to supply the Netherlands with an H1N1 flu virus vaccine because it could not supply the product within the required timeframe.

GREEN CROSS

South Korea's Green Cross is expected to benefit from the country's H1N1 preparations as the government has set aside $155 million to secure vaccines. Analysts reckon talks with South Korean authorities will guarantee Green Cross to deliver 50 percent of the vaccine supply, but there are concerns about its production capacity.

HUALAN BIOLOGICAL

A Chinese panel of experts gave a green light to a vaccine from Hualan Biological this week. Shares in the Shanghai-listed company have risen 44 percent in two weeks, hitting a life high.

INOVIO BIOMEDICAL

U.S. group Inovio has said its DNA-based H1N1 flu vaccines provided protection against the swine flu strain in pigs and mice. It said in August it expects to begin manufacturing vaccine supplies for H1N1 clinical studies in a "matter of weeks," even though it does not yet have the U.S. approval to begin human trials for that indication.

NOVAVAX

U.S. biotech company Novavax has a new kind of influenza vaccine that works against the swine flu virus in animals. It would have to get approval from the U.S. Food and Drug Administration before it could test the new vaccine in people and years of testing are likely to be required before such a new formulation could be widely used in humans.

THE WALL STREET JOURNAL

Betsy McKay

Swine Flu Remains mild as Vaccine Advances

The Wall Street Journal, 4 September 2009, 12:01 ET.
https://www.wsj.com/articles/SB125198466331383281

CDC study shows most U.S. children who died had pre-existing conditions; China makes headway with one-dose formula.

The H1N1 swine-flu virus is sickening many people around the world, but so far isn't becoming more virulent, health experts said Thursday, giving a bit of breathing room to pharmaceutical companies and officials rushing to deliver a vaccine.

"The good news is that so far, everything that we've seen, both here and abroad, shows that the virus has not changed to become more deadly," said Thomas Frieden, the director of the U.S. Centers for Disease Control and Prevention. "That means that although it may affect lots of people, most people will not be severely ill." But he cautioned that "the H1N1 influenza and influenza generally is unpredictable."

A CDC study Thursday showed that most of those U.S. children who have died of the new H1N1 flu were at least five years old, and 67% had high-risk medical conditions, predominantly neuro-developmental disorders such as epilepsy or cerebral palsy. Some otherwise healthy children who died had bacterial infections, the study found, warning doctors to be on the lookout for them so they could be treated quickly.

Health officials welcomed early evidence that one dose of the new H1N1 vaccine may be sufficient to protect some people from infection. If that finding bears out, public health authorities would be able to stretch limited supplies of vaccine to a larger portion of the population.

Their assumption has been that most people would need two doses to build enough immunity to the new virus. World-wide, the new flu has been confirmed to have infected more than 209,438 people, and at least 2,185 have died, according to the World Health Organization.

Chinese vaccine maker Sinovac Biotech Ltd. won approval from China's drug regulator for commercial production of that country's first H1N1 swine-flu vaccine, and said it is effective with a single standard dose. Novartis AG also said that its H1N1 swine-flu vaccine also prompted a strong immune response after a single dose in a pilot trial. The company said that two doses provided better protection, but that the study suggested one dose could be enough to protect adults against swine flu.

"While we do not yet have full details, these appear to be encouraging results," Marie-Paule Kieny, the WHO's vaccine research director, said of the findings.

U.S. officials are hoping for similar results from their own clinical trials. The Chinese vaccine is similar to shots being tested in the U.S., according to Anthony Fauci, director of the National Institute of Allergy and Infectious Diseases. Initial results are expected sometime in the next two weeks.

The WHO has warned that there isn't enough production capacity to produce shots for the world's entire population. About 25 companies are making H1N1 pandemic vaccines, including Sanofi Aventis SA, GlaxoSmithKline PLC and Novartis. The U.S. has ordered 195 million doses from five companies, and is expected to take delivery of the first 45 million to 52 million doses in mid-October.

The WHO has asked vaccine manufacturers to set aside at least 10% of their vaccine production for the developing world, and is talking with governments, as well as potential nongovernmental donors, about helping poor countries obtain vaccine. The WHO is trying "to do whatever we can to improve access in developing and poor countries to vaccine. This is a high priority for us," said Keiji Fukuda, the WHO's assistant director-general for health security and environment.

So far, though, only two companies have agreed to donate doses for developing nations, according to the WHO: Sanofi with 100 million doses, and GlaxoSmithKline with 50 million. The agency is also trying to obtain a portion of H1N1 vaccine production from other manufacturers at reduced prices, and is providing seed financing and technical assistance to 11 vaccine manufacturers in developing countries.

China is among the countries the WHO is pressing to donate vaccine for the developing world. China says that by the end of the year its vaccine manufacturers will produce enough vaccine for about 65 million people – or about 5% of its population. That would exceed China's usual seasonal flu-vaccination rate.

Demand for the vaccine is potentially vast in China. The country's work force plays a critical role in world manufacturing, and the global economy could be affected if large numbers of Chinese become ill. Some scientists also fear that if H1N1 were to spread in China's huge population, chances would increase that it could mix with other viruses such as avian influenza and become more deadly.

Mao Qunan, a spokesman for China's Ministry of Health, said experts are discussing how to allocate the vaccine and which groups of people should have priority for immunization, which he said should "start as soon as possible." He said Beijing as yet has no specific plans about providing vaccine outside China, but that "we will do our best" to help other developing countries.

Liu Peicheng, a spokesman for Sinovac, said specific plans for the distribution and use of its vaccine would be decided by the government. "The priority is to meet the domestic demand. The surplus will be provided to other countries," he said. Sinovac is supposed to supply five million doses of the vaccine by Oct. 1, and annual capacity would be 20 million to 30 million doses, the company said.

DERSTANDARD

Minister:

"Zwangs-impfung ist sicher nicht notwendig"
Stöger: "Panik ist nicht notwendig."

Der Standard, 6 September 2009, 18:47
https://web.archive.org/web/20091019014454/
http://derstandard.at/fs/1252036709195/
Minister-Zwangsshyimpfung-ist-sicher-nicht-notwendig

Vorsichtig, aber nicht hysterisch will Gesundheitsminister Alois Stöger mit der Schweinegrippe umgehen - Er werde sich nicht impfen lassen

Standard: Droht mit dem Schulbeginn eine weitere Ausbreitung der Schweinegrippe?

Stöger: Wir gehen nicht davon aus. Es wird möglicherweise im Herbst, in der normalen Grippesaison, mehr Erkrankungen geben. Verglichen mit den Ländern in der südlichen Hemisphäre ist der Verlauf bei uns sehr milde, die Ansteckung ging nicht in der Geschwindigkeit vor sich, wie das die WHO befürchtet hatte.

Standard: Waren die getroffenen Maßnahmen, etwa die rasche Entwicklung des Impfstoffes, übertrieben?

Stöger: Wenn die Weltgesundheitsorganisation die Pandemiestufe sechs ausruft, muss eine Gesundheitsbehörde handeln - das haben wir getan. Wir sind mit dem Virus sehr vorsichtig umgegangen und haben den schlimmsten Fall zur Vorbereitung angenommen. Die Menschen brauchen Sicherheit, sie können sich auf die Gesundheitsbehörden verlassen. Aber wir machen keine Hysterie. Panik ist nicht notwendig. Wir haben vorgesorgt für Menschen, die sich impfen lassen wollen. Aber eine flächendeckende Zwangsimpfung ist sicher nicht notwendig.

Standard: Werden Sie sich selbst impfen lassen?

Stöger: Nein, ganz sicher nicht. Ich gehöre nicht zu den Risikogruppen. Es wird aber genügend Impfstoff geben für diejenigen, die das wollen. (Andrea Heigl/DER STANDARD, Printausgabe, 7. September 2009)

Zur Person: Alois Stöger (49) ist als Gesundheitsminister für die österreichischen Pandemiepläne verantwortlich.

Junk Science and Contradictions Dominate WHO Pandemic Statements and Policies

Prevent Disease, 8 September 2009
https://web.archive.org/web/20090915190037/http://preventdisease.com/news/09/090809_swine_WHO_junk_science.shtml

The World Health Organization (WHO) claims that by employing their monitoring standards on outbreaks from different parts of the world, they are able to obtain sufficient information to make tentative conclusions about how the influenza pandemic might evolve in the coming months. Much of the clever phrasing on the WHO website is convincing enough to conceal the fact that all their pandemic policies on response and preparation recommendations are based on pure speculation and junk science.

More and more investigations on the flu pandemic hype are exposing the malicious intent by the agencies involved. The hype which has been so masterfully publicized by the WHO, CDC and other government agencies, is simply an evolving perpetual motor of deception.

Some of the myths propagated by the WHO are as follows:

WHO Claim: **H1N1 is now the dominant virus strain**

The WHO claims that the evidence from multiple outbreak sites demonstrates that the H1N1 pandemic virus has rapidly established itself and is now the dominant influenza strain in most parts of the world.

This is extremely deceptive of the WHO since they admit they are routinely re-categorizing a large number of cases of common influenza as H1N1 swine flu. The WHO stated in a briefing note that the "…increasing number of cases in many countries with sustained community transmission is making it extremely difficult, if not impossible, for countries to try and confirm them through laboratory testing. Moreover, the counting of individual cases is now no longer essential in such countries for monitoring either the level or nature of the risk posed by the pandemic virus or to guide implementation of the most appropriate response measures. ”

They also admit that:

- they will not collect data on the spread of H1N1 based on systematic lab confirmation.
- they will discourage national health officials to conduct detection and laboratory confirmation, while also pressuring the countries' public health authorities to duly deliver to the WHO on a weekly basis the data on H1N1 cases.
- they will only refer to "confirmed cases”. They do not distinguish between confirmed and non-confirmed case. It would appear that the "non-confirmed” cases are categorized as confirmed cases and the numbers are then used by the WHO to prove that the disease is spreading.

Reality: Since the swine flu has the same symptoms as seasonal influenza, the widespread incidence of the common flu is being used to generate the confirmed case H1N1/swine flu reports delivered to the WHO. Therefore, without laboratory evidence, it is impossible (scientifically or otherwise) for the WHO to ascertain any reliable evidence that H1N1 is the dominant virus strain. They routinely use such junk science in dealing with the body of pandemic facts and truths.

WHO Claim: **Pandemic flu is not the same as seasonal influenza**

They claim that there are differences between patterns of illness reported during the pandemic and those seen during seasonal epidemics of influenza. Specifically, they imply that age groups affected by the pandemic are generally younger than those of seasonal influenza.

The WHO is knowingly misleading the public with their claims. On their own website, they specify that "yearly influenza epidemics can seriously affect all age groups." Moreover, by insisting that "most of the severe cases and deaths have occurred in adults under the age of 50," they are specifically targeting populations with the largest demographic age group. Their intention is to endorse the greatest compliance for public administration of vaccines and the highest profits to the pharmaceutical industry. Without any scientific evidence, they promote these assumptions and advertise their fictitious data and opinions as facts.

The symptoms of seasonal influenza are known to be quite mild for the majority of the population. Coincidently, the WHO continues to define the severity of the H1N1 virus as an illness requiring neither hospitalization nor even medical care. Most cases are having mild symptoms that clear up on their own, very much like seasonal influenza. These types of contradictory statements are littered throughout the WHO literature and their policies.

Reality: There is no substantive or credible nature to this claim since the WHO will not collect data on the spread of H1N1 for ANY age group based on systematic lab confirmation. The fact that they are not distinguishing between confirmed and non-confirmed cases strongly translates this claim into pure conjecture.

WHO Claim: **Pregnant Women are a vulnerable group**

According to the WHO, there is an increased risk of the pandemic flu during pregnancy which is well-documented across countries. They further state that this risk takes on added significance for this virus since it preferentially infects younger people.

Pregnant women have been identified as being at high risk of complications resulting from H1N1 flu, following publication of research in the Lancet medical journal in July. As a result, officials on both sides of the Atlantic have identified mothers-to-be as priority cases for the fast-tracked vaccine, despite the fact that relatively nothing is known about the possible side effects of the vaccine on unborn babies. => https://www.theguardian.com/world/2009/jul/29/swine-flu-pregnant-woman-lancet

Just as there was no evidence of the avian flu virus mutating to cause a pandemic, there is also no evidence of any mutagenic process involved in the H1N1 swine flu virus. Talmage Holmes, a relationship manager for the Centers for Disease Control and Prevention (CDC) in Columbus, Ohio, states that pregnant women should not have any special worries. "Pregnant women are at no greater risk than others." says Dr. Holmes. "Until there has been mutation or re-assortment of the avian flu virus' genetic material, the risk to all humans is very low."

Reality: To date, there are NO well-documented case studies in any country that establish pregnant women as having an increased risk for pandemic flu. Globally, the effects of the H1N1 swine flu virus have been relatively mild and it has behaved no differently than any other influenza virus. The WHO is well aware of this fact despite its tireless effort to advocate the opposite by manipulating the data. By targeting pregnant women, the WHO is attempting to instigate fear which they hoped would activate the maternal protective reponse in women who would then opt for the vaccine. In reality, it has accomplished the opposite effect. According to the results of recent polls on mumsnet.com, just 6% of pregnant women say they definitely will take the swine flu vaccine to protect their children.

WHO Claim: **Regulatory procedures for pandemic vaccines are rigorous and do not compromise safety.**

According to the WHO, they attempt to shorten the time between the emergence of pandemic viruses and the availability of safe and effective vaccines.

For example, to fast-track vaccines, they only require minimal data from manufacturers who already have licensed influenza vaccines if they intend on using the same manufacturing process for pandemic vaccines.

One such method used in Europe is to conduct advance studies using a "mock-up" vaccine that contains an active ingredient for an influenza virus that has not circulated recently in human populations.

When testing these mock-up vaccines, it is very possible to release the novel influenza virus into the population, as its purpose is to "mimic the novelty of a pandemic virus" and "greatly expedite regulatory approval."

Why are the potential effects of releasing a viral strain to which humans have acquired NO immunity for? This alone is an extremely dangerous practice which leaves gaping holes in the safety protocols at the WHO.

They also claim that fast-tracked vaccines will require post-inoculation testing to validate vaccine safety. "Time constraints mean that clinical data at the time when pandemic vaccines are first administered will inevitably be limited. Further testing of safety and effectiveness will need to take place after administration of the vaccine has begun." In other words, the first groups or populations treated with the vaccine are human experiments.

Reality: This clearly demonstrates the irresponsible nature of WHO pandemic policy. The fast-tracked pandemic vaccines they attempt to regulate and approve are those with the least safety testing prior to being used. This potentially gives vaccine manufacturers the green light to develop medically approved poison with no regard to human health. They compromise safety in every respect.

WHO Claim: **Influenza vaccines have been used for more than 60 years and have an established record of safety in all age groups.**

Reality: For the last 60 years, influenza vaccines have contained combinations of the following: Ammonium sulfate, polysorbate 80, thimerosal, formaldehyde, egg or chicken protein, antibiotics and aluminum, among others. Each of the above ingredients are toxic and pose a scientifically established hazard when injected into the human body. The long-term adverse effects of vaccines and their additives are no longer questioned by hundreds of internationally recognized scientists. The facts are clear, the risk of vaccines outweigh any benefits to human health.

Inoculations are the true weapons of mass destruction, and have absolutely no correlation to disease prevention. Vaccines have caused millions of chronic health ailments and deaths in the last 60 years. The statements made by the WHO claiming "an established record of safety in all age groups" is at the very least outlandish and criminal.

CHINA.ORG.CN

China issues world's first warrant for A/H1N1 flu vaccination

China.org.cn, Xinhua News Agency, 8 September 2009, 16:11
http://www.china.org.cn/government/central_government/2009-09/08/content_18481874.htm
http://www.china.org.cn/government/central_government/2009-09/08/content_18481874_2.htm

Beijing, Sept. 8 (Xinhua) – China has issued its first warrant for mass inoculation with domestic A/H1N1 flu vaccine, the first country in the world to do so, Health Minister Chen Zhu said Tuesday.

Chen said the warrant was issued by the State Food and Drug Administration Monday after the safety and effectiveness of the vaccines had been proved in clinical tests.

The first people to receive the vaccinations will be those attending celebrations for the 60th anniversary of the founding of the People's Republic of China, Chen said.

The celebration on Oct. 1 consists of a military parade, a mass pageant and a gala. The pageant alone will involve about 200,000 citizens.

Chen said protection would also be given to vulnerable groups, such as carriers of chronic disease, school students and medical staff.

"We will also consider the differences between regions and start the vaccinations in areas where flu situations are serious," Chen said.

Chen said the vaccination plan had been drafted on the basis of repeated and conscientious work by medical experts, with advice from the World Health Organization (WHO).

Besides vaccination, other preventive measures, such as education for the public on prevention, would be carried on to keep the epidemic in a "controllable state", Chen said.

"We will improve information channels and formulate prevention plans targeting railway and a

"We will also improve treatment methods," he said. "Apart from respiratory and anti-virus medicines, we will use traditional Chinese medicine."

Chen said the medical system was prepared to treat patients "ona large scale", especially those showing severe symptoms.

By Monday, all 31 provinces and municipalities on the Chinese mainland had reported A/H1N1 flu cases, bringing the total to 5,592. So far, nearly 70 percent have recovered and no deaths have been reported.

Both the WHO and domestic experts say they believe the A/H1N1 flu epidemic will reach the peak in autumn and winter, Chen said.

He said China's situation was "grim" given the large number of students who started the new semester in September and the National Day celebrations.

In the past week, 95 percent of newly confirmed A/H1N1 flu cases were locals, he said.

Since late-June, China has reported 128 cases of group infections. In some provinces there has been a rising proportion of A/H1N1 flu cases against other flu-linked illnesses.

On Friday, Shanghai reported an A/H1N1 flu patient showing severe symptoms, including respiratory and multi-organ function failures. On Sunday, eastern Zhejiang Province reported another patient in a critical situation with adult respiratory distress syndrome.

The Shanghai patient, though not completely out of danger, has shown signs of improvement, Chen said. The Zhejiang patient is also in a less critical situation.

A meeting presided over by Premier Wen Jiabao on Monday vowed to step up the prevention and control of the A/H1N1 flu virus in the run-up to the National Day celebrations.

Schools are currently the key battlegrounds in China's fight against the virus and classes would be suspended "properly" to avoid mass infection when an outbreak occurs, the meeting decided.

China's ability to produce A/H1N1 flu vaccines is still limited compared with its 1.3 billion population, Chen said.

"Therefore, we still need to carry out preventive measures proved effective previously, especially the public's ability to protect itself," he said.

Schweinegrippe: Impfstoff-Versuche an Kindern

MM News, 8 September 2009
https://web.archive.org/web/20090911015002/http://www.mmnews.de/index.php/200909083720/MM-News/Schweinegrippe-Impfstoff-Versuche-an-Kindern.html

Die Uni-Klinik Rostock sucht Kinder im Alter von 3 bis 18 Jahren für Impfstoff-Tests gegen Schweinegrippe. Belohnung: 250 Euro. Auftraggeber: Novartis. Ausgang: unbekannt. Eltern stellen Kinder als Versuchskaninchen zur Verfügung.

In einer Anzeige der Ostsee-Zeitung sucht das Tropenmedizinische Institut der Universitätsklinik Rostock nach Testkandidaten für einen Impfstoff gegen Schweinegrippe. Den jungen Teilnehmern wird der Impfstoff im Wochenabstand drei mal eingespritzt. Nach einem Jahr stehen dann noch mal zwei Termine beim Arzt an.

Untersucht werden soll, ob der vorgesehene Impfstoff von Novartis zu unerwarteten Nebenwirkungen führt, erklärte der verwantwortliche Mediziner. Er rechne zwar nicht, dass solche Nebenwirkungen auftreten, aber eine 100%-Garantie könne man derzeit nicht geben - deshalb seien die Tests erforderlich.

Auf die Frage, ob der das Projekt leitende Arzt sich selbst und seine Kinder auch schon gegen die Schweinegrippe impfen lassen würde, antwortete der Mediziner mit "ja".

Derzeit laufen weltweit Tests mit Kindern und Jugendlichen, um die Unbedenklichkeit des Novartis-Impfstoffs zu testen. Insgesamt werden 600 Testkandidaten benötigt. 200 davon werden aus Deutschland rekrutiert.

Nach Aussagen des Mediziners seien die Tests an Erwachsenen weitgehend abgeschlossen. Nun müsse noch überprüft werden, wie Kinder und Jugendliche reagierten.

Über mögliche Nebenwirkungen äußerte sich der Arzt folgendermaßen:

Rötungen an der Einstichstelle, Druck, grippeähnliche Beschwerden, Kopfschmerzen, Gelenk- und Muskelschmerzen. Fehlsteuerungen des Immunsystems.

Auf die Frage, ob eine generelle Impfung überhaupt sinnvoll sei, da die Schweinegrippe doch bisher glimpflich verlaufe, erläuterte der Mediziner, dass das Virus jeder Zeit mutieren könne und damit gefährlich werden könne.

Ob jedoch gegen ein mutiertes Virus der Impfstoff noch hilft, bleibt fraglich.

Dem Vernehmen nach nutzen besonders arme Familien den Impfstoff-Test als willkommene Einnahmequelle und bringen ihre Kinder in die Klinik. Pro Termin gibt es 50 Euro - insgesamt locken 250 Euro für 5 Termine.

Biotech companies benefiting from flu outbreak

Reuters, 8 September 2009, 3:43pm EDT
http://www.reuters.com/article/healthNews/idUSTRE5875SM20090908?virtualBrandChannel=10522

(Reuters) - Here is a list of biotech companies whose shares may rise or fall depending on the course of the swine flu pandemic.

GILEAD SCIENCES INC - Receives royalties on sales of the Tamiflu pill, which Roche Holding AG sells under license from Gilead. According to analysts at Barclays Capital, current projections for the second half of the year suggest combined seasonal and pandemic Tamiflu sales of $1 billion.

BIOTA HOLDINGS LTD - The Australian biotech company receives royalties on sales of the inhaled antiviral drug Relenza, which is marketed by GlaxoSmithKline Plc. Biota's royalties more than doubled to $37.5 million in the year to June. The company is developing a new flu drug, laninamivir, with Daiichi Sankyo. Late stage studies in Asia showed a single dose of inhaled laninamivir alleviated flu as effectively as five days of twice-daily Tamiflu.

* NOVAVAX INC - Will apply to U.S. Food and Drug Administration in the fourth quarter to start human clinical trials of its H1N1 vaccine. An earlier trial of the virus-like particle (VLP) vaccine showed it protected ferrets from swine flu. The vaccines can be grown in caterpillar cells and can be produced much quicker than traditional vaccines made using chicken eggs.

* BIOCRYST PHARMACEUTICALS INC - Has intravenous antiviral called peramivir in late stage development. A late-stage trial sponsored by partner Shionogi & Co Ltd of Japan showed peramivir was no less effective than Tamiflu.

* VICAL INC - Developing a gene-based vaccine using its Vaxfectin adjuvant, which boosts the immune system. Early trials showed it produced a robust immune responses in animals. The company is developing vaccines against the H5N1 avian flu strain and the new H1N1 virus.

* INOVIO BIOMEDICAL CORP - Developing DNA-based H1N1 flu vaccines that protect pigs and mice. It will jointly develop universal influenza vaccines -- vaccines that target several strains of the virus -- with the National Institutes of Health's research unit.

* MEDICAGO INC - The Canadian biotech makes protein-based vaccines through the genetic engineering of plants such as tobacco. It is working to form agreements in different geographies. Most recently, it said it expects to sign a licensing agreement with a Middle East company that will pave the way for the say for the development of its swine flu vaccine in the region.

* GENEREX BIOTECHNOLOGY CORP - Making synthetic peptide vaccines. These differ from egg-based vaccines in that they do not use a live virus. Instead, peptides are arranged so as to mimic

the virus, priming the immune system. The vaccines are designed to be produced more quickly than traditional vaccines. Generex will apply to U.S. regulators in the fourth-quarter to start human trials.

* CRUCELL NV - The Dutch biotech plans to begin clinical trials of its experimental antibody-based flu drug mAB CR6261 next year. The company's PER.C6 technology uses human cells rather than chicken eggs to produce an antibody to prevent a infection with a variety of flu viruses.

* CSL Ltd - Australia's CSL has completed its first batch of 2 million shots in 15 microgram doses and is producing up to 1.5 million doses per week until it fills orders, which include an order for 21 million doses from the Australian government and $180 million in orders from the United States.

* GREEN CROSS - Green Cross, the only South Korean drug company that can mass produce an H1N1 flu vaccine, has signed a $7.4 million supply deal with the government, which secured 1.1 million doses of the vaccine for delivery by the end of November.

SINOVAC BIOTECH LTD - The China-based company is the first worldwide to complete clinical trials of an H1N1 flu vaccine. It said the vaccine, which is given in a single dose, rather than the two doses typical for a vaccine, is ready for delivery. Sinovac expects to produce 30 million doses.

HUALAN BIOLOGICAL - A Chinese panel of experts has given the green light to the Shanghai-listed company's vaccine. It is expected to be approved there this month.

THE FLU CASE

Ineffectiveness of seasonal flu vaccines
Report in Chinese on the "swine flu" jab risks

The Flu Case, 9 September 2009
https://web.archive.org/web/20090917131846/http://www.theflucase.com/index.php?option=com_content&view=article&id=535%3Areport-in-chinese-on-the-qswine-fluq-jab-risks&catid=1%3Alatest-news&Itemid=64&lang=en

11) Ineffectiveness of seasonal flu vaccines

Given the rush to get H1N1 influenza vaccines into production, it is unlikely that there will be much, if any data, on the effectiveness of these vaccines in preventing H1N1 influenza or its complications before the vaccine is released into the market. The "efficacy" of influenza vaccines is a term used to describe its effect in creating an antibody response; this does not necessarily mean that the vaccine will protect against infection. Influenza vaccines have a long history of producing disappointing results in terms of preventing influenza or influenza like illness. A recent article published in the British Journal of Medicine stated that:

"In children under 2 years inactivated vaccines had the same field efficacy as placebo,8 and in healthy people under 65 vaccination did not affect hospital stay, time off work, or death from influenza and its complications.9"

The author also expressed surpise at the lack of safety studies:

"A Cochrane Database Systematic Review found only one old trial with data from 35 participants aged 12-28 months.8 In the general population of elderly people, despite a dataset of several million observations, safety was only reported in five randomised controlled trials (2963 observations in total) on local and systemic adverse events seen within a week of giving parenteral inactivated vaccine."

He recommended that in light of the evidence poor effectiveness of inactivated influenza vaccine, poor methodology of some studies and the surprisingly small amount of information relating to vaccine safety, that a "a re-evaluation [of influenza vaccination programmes] should be urgently undertaken." => http://www.bmj.com/cgi/content/full/333/7574/912

Concluding Comments:

Given that seasonal influenza vaccines do not appear to be very effective in preventing influenza like illness or complications and the fact that the serious concerns have been raised about the safety of H1N1 pandemic influenza vaccines, the decision about whether or not to receive an H1N1 vaccine is one that should be made very carefully. (Certainly, at the very least, potential candidates for vaccination would do well to study the vaccine manufacturer's datasheet when this is available before making a decision about the vaccine). In New Zealand the decision about whether or not to be vaccinated has always been made by the individual concerned (or the parents/guardians of a child aged under the age of 16 years).

It is a basic human right that individuals give informed consent to any proposed medical treatment, including vaccination. It is crucial to the well-being of both individuals and our country as a whole that we resist any attempt by the State to erode individual rights and freedom of choice by making vaccination against H1N1 influenza compulsory for any group of New Zealanders or within the country as a whole. Considering that the World Health Organisation influences the health policies of every country in the world, citizens of countries other than NZ would do well to look at the policies of their country's Ministry of Health and relevant national legislation and take whatever steps necessary to preserve (or regain) freedom of choice when it comes to vaccination.

Thomas Stephens

Progress made on swine flu vaccine

Swiss Info, September 11, 2009, 13:42
https://www.swissinfo.ch/eng/progress-made-on-swine-flu-vaccine/1007006

Less deadly than initially feared, the A/H1N1 flu pandemic will soon be up against a vaccine, expected to be available between mid-October and November.

Delivery in Switzerland will be spread out between the end of September and mid-October, but the date of the first actual jabs remains open, says Claire-Anne Siegrist, president of the Federal Vaccination Commission.

Definitely between the second half of October and November, according to swissmedic, the Swiss agency for therapeutic products.

Similar to the annual fight against seasonal flu, vaccines will be first administered in Switzerland to people at risk. The US Centers for Disease Control and Prevention has said this category includes pregnant women, children younger than five and people with certain chronic conditions like asthma and heart disease.

In a second stage, a couple of weeks later, anyone wishing to vaccinate themselves or their immediate family could do so.

Pascale Boyer Barresi, a financial analyst at private bank Bordier, sees this happening from December or January.

Switzerland has ordered 13 million doses from pharmaceutical companies Novartis and GlaxoSmith-Kline. Novartis confirmed to swissinfo.ch that deliveries will be ready on an international level between October and the beginning of 2010.

The Basel-based firm said it could produce 150 million doses a year, mainly from its units in Germany, Italy, Britain and, from November, the United States.

So far more than 1,100 cases of A/H1N1 have been reported in Switzerland and Liechtenstein. Since July, 18 people have been admitted to hospital, some for complications arising from the flu and others among risk groups such as pregnant women.

Highly specialised

Novartis uses two techniques: the traditional method – still responsible for about 90 per cent of the world's flu vaccines – of injecting the virus into chicken eggs, and cell culture.

This second method, which involves cells being grown under controlled conditions, is "much more profitable in terms of productivity but does require highly specialised equipment, which is expensive", said Boyer Barresi.

"The cost price would double. I'd be astonished if they sold their vaccine at a loss – but with a limited mark-up, without doubt."

He expects Novartis, Sanofi Pasteur, Baxter and GlaxoSmithKline to bring their respective vaccines onto the market more or less simultaneously, "having been given access to the genetic properties of the virus at the same time and possessing similar development capacities".

These four pharmaceutical firms will share the northern markets. China and India are also looking to respond to global needs.

One dose or two?

Optimum quality is one of the criteria used by Switzerland when considering a vaccine.

Also important is the presence of an adjuvant, a chemical component used to stretch a vaccine's active ingredient and essentially make it more efficient.

The strength of the immune response is important in determining not just that the vaccines work but how many doses people will need. Because swine flu is a new strain, many infectious disease experts have been expecting people will need two doses to get full immunity against the virus.

However, Novartis said last week that a single dose of one of its experimental vaccines appeared to protect against the virus, raising hopes that potentially tight supplies could go further when mass immunisation gets under way.

According to Novartis, people who got two injections of vaccine had a better immune response, but just one injection also provided adequate protection within two weeks of the vaccine being given.

"It is very rare for a virus to circulate only once," said Siegrist, adding that experts were expecting one or more waves but were unable to predict when.

Commission Staff Working Document [SEC(2009) 1191 final]
Regulatory process for the authorisation of antiviral medicines and vaccines in the protection against Pandemic Influenza (H1N1) 2009

Brussels, Commission of the European Communities, 15 September 2009
https://eur-lex.europa.eu/legal-content/PT/ALL/?uri=CELEX%3A52009SC1191

Accompanying document to the
Communication from the Commission to the Council, the European Parliament and the European Economic and Social Committee and the Committee of the Regions. Pandemic Influenza A (H1N1) 2009; {COM(2009) 481}; {SEC(2009) 1188}; {SEC(2009) 1189}; {SEC(2009) 1190}; {SEC(2009) 1192}

Executive Summary and Conclusions
On 11 June 2009 the WHO declared the influenza pandemic. Moreover the Strategic Advisory Group of Experts (SAGE) of the WHO recommended that healthcare workers should be vaccinated as a first priority to protect the essential health infrastructure. SAGE suggested the following order of priority encompassing the whole population: pregnant women, those aged above 6 months with one or several chronic medical conditions, healthy young adults of 15 to 49 years of age, healthy children, healthy adults of 50 to 64 years of age, and healthy adults of 65 years of age and above. WHO endorsed these recommendations on 11 July 2009.
https://web.archive.org/web/20090714231253/http://www.who.int/csr/disease/swineflu/notes/h1n1_vaccine_20090713/en/index.html

The EU Member States are responsible for the definition and implementation of any strategy for vaccination, while both the EU and the Member States are carrying responsibilities for the authorisation of vaccines and for the needed pharmacovigilance. On this basis, Member States developed a shared approach for priority groups for vaccination, which was published on 25 August 2009. http://ec.europa.eu/health/ph_threats/com/Influenza/docs/HSC_EWRS_statement_en.pdf

The EU has already started taken action to tackle the pandemic. While various anti-viral medicines received approval for marketing in the past and are available for treatment of pandemic influenza in the EU, new measures have been concentrated on an accelerated assessment of new applications for marketing authorisations of Influenza A (H1N1) vaccines and variations thereof. Both the European Medicines Agency (EMEA) and Member States have received or are expecting applications for market authorisations and variations thereof. Community legislation provides for a sound legal framework to address the challenges of a pandemic influenza. For defined categories of medicinal products, such as vaccines manufactured using a biotechnological process, the central authorisation process for marketing is mandatory. The national authorisation procedure is applicable to all other procedures and under certain conditions there is a choice between the two procedures. On the basis of these provisions, swift scientific assessment of Influenza A (H1N1) 2009 vaccines by the EMEA and a swift subsequent Commission Decision on the marketing authorisation will be ensured with the objective to have substantial amounts of safe vaccines available across the EU 27.

Moreover, Community legislation has specific legal provisions in the case of a declared pandemic influenza. The Commission has underpinned legislation by regulatory guidelines and the EMEA has, through its scientific committees, adopted scientific guidelines including guidelines for pandemic vaccines. Specifically designed processes for the scientific evaluation of a variation of pandemic vaccines are intended to allow for best possible planning reliability in the case companies

intend to start early production. In addition, the EMEA is in close contact on an exchange and sharing of strategies for drug development, assessment and scientific information with major international partners, with which a confidentiality agreement exists (US, Canada, Japan).

Scientific assessment of the risk-benefit balance of any vaccine to be authorised for the protection against Influenza A (H1N1) 2009 will be important on the basis of available data in the current pandemic situation. In any case depending on the evolvement of the real situation the EU has all means at its disposal to act as rapidly as needed. Equally important for public trust and confidence is pharmacovigilance. After an authorisation for marketing of vaccines has been granted, companies will be subject to intensive pharmacovigilance monitoring and reporting obligations. When deemed necessary from a risk-benefit perspective, competent authorities will take the necessary actions with respect to the marketing authorisation granted. This may include, but is not limited to, a widening or a restriction of the scope of the marketing authorisation with respect to patient population, contra-indications and posology amongst others.

The Commission will facilitate as much as possible cooperation and the exchange of information. Cooperation with WHO is crucial. In order to develop vaccines against novel influenza, manufacturers depend on the isolation and supply of the relevant virus strains by the World Health Organization, which provided the Influenza A (H1N1) 2009 strains in May 2009. In addition, the WHO may proceed to issue specific recommendations for the development of this vaccine and on the continued production of seasonal vaccines. Furthermore, after the declaration of the pandemic by WHO there are specific provisions which allow certain flexibility on the extent of data requirements to support a marketing authorisation application and variations thereof, and the subsequent timeframe for its regulatory assessment. *In any case the risk-benefit assessment has to be positive for each vaccine*.

...

3.5. Specific legal provisions for the distribution by Member States

As a general rule, marketing authorisation holders are subject to liability for the use of their products as long as they are used within the terms of the marketing authorisation. Member States may temporarily authorise the distribution of an unauthorised medicinal product in response to the suspected or confirmed spread of pathogenic agents. This encompasses pandemic situations, such as the Influenza A (H1N1) 2009 pandemic. In such a case marketing authorisation holders, manufacturers and health professionals are not subject to civil or administrative liability for any consequences resulting from the use of a vaccine when such use of an unauthorised vaccine is recommended or required by a competent authority in response to the pandemic situation. This also applies when the use of an authorised medicinal product, such as an antiviral medicine and a vaccine, is recommended beyond authorised conditions (e.g. indications, age groups). These provisions apply independently whether a national or Community authorisation has been granted.[23]

European Commission gave Big Pharma blanket Immunity before start of Swine Flu campaign

The Flu Case, 28 December 2009

https://web.archive.org/web/20100102013146/http://theflucase.com/index.php?option=com_content&view=article&id=2414%3Aeuropean-commission-gave-big-pharma-blanket-immunity-before-start-of-swine-flu-campaign&catid=1%3Alatest-news&Itemid=64&lang=en

Days before implementing the biggest mass vaccination campaign in history this autumn, the European Commission issued a directive giving pharmaceutical companies and governments total immunity from liability for any damages caused by the untested swine flu jab and Tamiflu, even when the drugs were used inappropriately... etc.

Maggie Fox

Flu experts gear up for pandemic of vaccine worry

Reuters, 16 September 2009, 3:04pm EDT
https://web.archive.org/web/20100103013122/http://www.reuters.com/article/idUSTRE58F3A720090916

Yet this year, they know a significant number will be blamed on the H1N1 vaccine, which will roll out within weeks, and they are struggling to be ready.

They expect an avalanche of so-called adverse event reports, which are reports of death, illness or other health trauma that occur within two weeks after receiving treatment -- in this case, the swine flu vaccine.

"We are going to be overwhelmed with potential events," said Mike Osterholm, a public health expert at the University of Minnesota.

"Anything that happens to anybody in the period of seven to 14 days after vaccination will be reported."

And not just to U.S. officials. The World Health Organization is trying to reassure a global audience that vaccines being made by 25 different companies, with various formulations, are all safe.

"If we have a safety signal in one country it could stop vaccination efforts in others," WHO's top flu expert Dr Keiji Fukuda told a meeting of infectious disease specialists organized by the U.S. Institute of Medicine this week.

Flu experts themselves have little doubt the vaccine being made against H1N1 is safe. It is made using precisely the same technology as the annual seasonal flu vaccine, which is given to hundreds of millions of people every year.

But because H1N1 is new, vaccine makers have been testing it to learn what the right dose is.

Spirit of '76

Memories linger of the 1976 swine flu debacle, when 43 million Americans were vaccinated against a virus that never spread, and newspapers filled with reports of a rare and crippling neurological disease called Guillain-Barre syndrome.

Guillain-Barre was never definitively linked with the vaccine, but many Americans have viewed immunizations with suspicion ever since.

"We have anticipated that there will be a need for enhanced surveillance for Guillain-Barre as well as other adverse events," Dr Nancy Cox of the U.S. Centers for Disease Control and Prevention told the meeting.

And there will be more to contend with than critical newspaper and television reports. The Internet did not exist in 1976. Nor did blogs, Facebook, Twitter or dozens of other ways for people to communicate globally and instantly.

"Information is the most globalized product of all," Fukuda said. "The ability of blog sites to influence countries' decision-makers and so on -- coming to grips with how we deal with this is going to be a priority."

To address this, CDC and the U.S. Food and Drug Administration are gearing up for one of the biggest surveillance efforts ever. "We know how absolutely essential clear, transparent communications are to the public in order to have a successful vaccination campaign," Cox said.

CDC's weapons of choice -- Facebook, Twitter, Internet RSS feeds, humorous "viral" videos posted on YouTube, iPhone apps such as the CDC News Reader. Children's Hospital Boston has an app (short for application) called Outbreaks Near Me that allows people to track the pandemic locally.

Susan Heavey

US approves H1N1 vaccine, says enough for everyone

Reuters, 16 September 2009, 5:28 AM GMT+8
https://www.reuters.com/article/idUSN1562056/

Washington, Sept 15 (Reuters) - U.S. health officials have approved vaccines from four drug-makers to help prevent the H1N1 swine flu, ensuring there will be enough to inoculate Americans who want the protection, U.S. Health Secretary Kathleen Sebelius told lawmakers on Tuesday.

The U.S. Food and Drug Administration cleared vaccines from Sanofi-Aventis SA , CSL Ltd , Medimmune [MEDI.UL] and Novartis AG for the H1N1 strain of influenza, she said.

"There will be vaccines for everyone," Sebelius said at a hearing of the U.S. House of Representatives Energy and Commerce Committee. There are about 300 million potential users, she said, adding that not all Americans will opt for the shot. The first doses should be available within the next four weeks, according to the FDA.

Manufacturers and governments have been scrambling for vaccines to target the new H1N1 flu strain, which was declared a pandemic in June. The World Health Organization said it could infect as many as one-third of the world's population, or 2 billion people.

Sebelius said the government has already contracted to buy 195 million doses from a total of five manufacturers and that more purchases are likely depending on how many people decide to get vaccinated.

GlaxoSmithKline Plc is also working to develop a H1N1 vaccine and win FDA approval.

Some skeptics have questioned the safety of the vaccines, especially given the quick development. Clinical trials for most adults began in early August.

So far, preliminary data show most healthy adults have a good immune response eight to 10 days after receiving a single shot, the FDA said. Other studies are underway for children, and trials for pregnant women just began, Sebelius said.

"The H1N1 vaccines approved today undergo the same rigorous FDA manufacturing oversight, product quality testing and lot release procedures that apply to seasonal influenza vaccines," Dr. Jesse Goodman, FDA's acting chief scientist, said in a statement.

Free Vaccines

U.S. officials are launching a large-scale vaccination effort in mid-October to inoculate the population, including those most at risk such as pregnant women and young people ages 6 months to 24 years. H1N1 vaccines will be free, Sebelius said, but some healthcare providers may charge an administration fee. The federal government is planning to spend about $1.4 billion for states and hospitals to prepare for the virus, she added.

Flu season typically runs from October to May, but U.S. officials saw H1N1 cases throughout the summer with an uptick from summer camps and now schools.

Still, people won't be able to get the vaccine for weeks. –

"The fact that vaccines won't begin distribution until October makes preventing the spread of flu even more critical," Sebelius said in her testimony.

GlaxoSmithKline obtient 20M$ de Québec

Les Affaires, 17 September 2009
https://web.archive.org/web/20100109023603/http://www.lesaffaires.com/secteurs-d-activite/biotechnologies-et-pharmaceutique/glaxosmithkline-obtient-20m-de-quebec/498273

Le montant a été accordé pour permettre à l'usine de l'entreprise à Ste-Foy, en banlieue de Québec, de remplacer une ligne de remplissage et d'emballage stérile de vaccins par une nouvelle ligne plus moderne et de plus grande capacité qui devrait entrer en service en 2012.

Le montant de 20 millions de dollars fait partie d'un financement de 60 millions de dollars accordé en partenariat avec le gouvernement fédéral annoncé le 9 septembre dernier. Ottawa accordera une subvention de 40 millions de dollars.

De plus, GlaxoSmithKline ajoutera 30 millions de dollars dans la mise à niveau de son usine, pour des investissements totaux de 90 millions de dollars.

Les travaux permettraient de plus que doubler la capacité de l'usine et de consolider ses 800 emplois.

En août, GSK a obtenu un contrat évalué à 400 millions de dollars du gouvernement canadien pour la fabrication de 50 millions de doses de vaccins contre la grippe A (H1N1).

ID Biomédical a été achetée en 2005 par la multinationale GlaxoSmithKline (GSK) pour un montant de 1,7 milliard de dollars.

China issues world's first warrant for A/H1N1 flu vaccination

CCTV, 17 September 2009, 14:06 BJT
http://english.cctv.com/program/worldinsight/20090917/103353.shtml

Beijing, Sept. 8 (Xinhua) - China has issued its first warrant for mass inoculation with domestic A/H1N1 flu vaccine, the first country in the world to do so, Health Minister Chen Zhu said Tuesday.

Chen said the warrant was issued by the State Food and Drug Administration Monday after the safety and effectiveness of the vaccines had been proved in clinical tests.

We will also improve treatment methods," he said. "Apart from respiratory and anti-virus medicines, we will use traditional Chinese medicine."

Chen said the medical system was prepared to treat patients "ona large scale", especially those showing severe symptoms.

By Monday, all 31 provinces and municipalities on the Chinese mainland had reported A/H1N1 flu cases, bringing the total to 5,592. So far, nearly 70 percent have recovered and no deaths have been reported.

Both the WHO and domestic experts say they believe the A/H1N1 flu epidemic will reach the peak in autumn and winter, Chen said.

He said China's situation was "grim" given the large number of students who started the new semester in September and the National Day celebrations.

In the past week, 95 percent of newly confirmed A/H1N1 flu cases were locals, he said.

Since late-June, China has reported 128 cases of group infections. In some provinces there has been a rising proportion of A/H1N1 flu cases against other flu-linked illnesses.

China first to vaccinate against novel H1N1 virus

Science, 18 September 2009; 325(5947): 1482-1483
doi: 10.1126/science.325_1482. PMID: 19762610.
https://www.science.org/doi/10.1126/science.325_1482

Abstract

Swine Flu Outbreak: No country has taken stricter measures than China to protect residents from pandemic swine flu.

Although its draconian quarantine system sparked scientific debate and more than a few diplomatic spats before it was scaled back a couple of months ago, China's latest exploit is winning praise:

Earlier this week, China was first off the blocks to launch a mass vaccination campaign against the novel H1N1 virus.

As the swine flu pandemic picks up steam, China is racing to immunize a sizable percentage of its 1.3 billion people before the pandemic's expected peak here this autumn or early winter.

Epidemiologists here forecast that, without mass vaccination, tens of millions will become infected in China and hundreds of thousands will seek treatment.

Beijing – No country has taken stricter measures than China to protect residents from pandemic swine flu. Although its draconian quarantine system sparked scientific debate and more than a few diplomatic spats before it was scaled back a couple of months ago, China's latest exploit is winning praise: Earlier this week, China was first off the blocks to launch a mass vaccination campaign against the novel H1N1 virus. "It's an impressive achievement," says biostatistician Ira Longini of the University of Washington, Seattle.

As the swine flu pandemic picks up steam, China is racing to immunize a sizable percentage of its 1.3 billion people before the pandemic's expected peak here this autumn or early winter. Epidemiologists here forecast that, without mass vaccination, tens of millions will become infected in China and hundreds of thousands will seek treatment, says Yang Weizhong, deputy director of the Chinese Center for Disease Control and Prevention (CDC).

China's lightning-fast vaccine effort might soften the blow. As of 14 September, Chinese authorities had 650,000 vaccine doses on hand and expect nearly 7 million more by the end of September. (U.S. manufacturers are slated to deliver 50 million doses by 15 October and 18 million a week thereafter.) In interviews with Science, the architects of China's campaign described how they managed to hold H1N1 at bay long enough to develop and test a vaccine that they hope will avert a collapse of China's fragile health care system. "Our hope is to delay the peak and particularly to reduce severe cases and prevent deaths," says Chen Zhu, China's health minister.

China's aggressive campaign, crafted shortly after the world learned of the swine flu outbreak in Mexico last April, "was based on our particular situation: a huge population, poor health care in rural areas, and a limited stock of antiviral medicines," says Liang Wannian, the health ministry's deputy director general and chief of its Center for Public Health Emergencies. His team knew that China's health system would be overwhelmed if tens of thousands of people at any one time – including medical workers – were hospitalized with the pandemic H1N1 virus. Another concern was that China is a reservoir of H5N1 avian influenza, which kills roughly half the people it infects. "We wanted to reduce the opportunities for H1N1 and H5N1 to mix," says Liang.

The country's stringent measures to keep out the virus – early on, screening overseas passengers before they disembarked and quarantining all cases and contacts – appear to have worked, for a while: China

reported its first nonimported case of pandemic H1N1 on 29 May, 2 weeks before the World Health Organization (WHO) raised the global pandemic alert to phase 6. But in early July, when it was clear the virus could not be stopped, China "adjusted its strategy to the situation," says Liang, bringing it in line with most other countries.

By mid-August, nonimported infections in China were climbing, and in the past 3 weeks, their number has doubled to nearly 7000 confirmed cases, with three severe cases and no deaths. The early quarantine "bought us time," says Liang – enough time, that is, to make a vaccine.

China received H1N1 virus stock from WHO in early June, a little later than multinationals such as GlaxoSmithKline and Aventis Pasteur, says Liang. "Immediately, our industry put all their capacity into production," he says. Ten Chinese companies got to work, with the State Food and Drug Administration (SFDA) riding herd. The "green channel" SFDA created to speed review of vaccine development saved about a month, says Liang. Rather than wait for WHO to work up reference reagent for H1N1 vaccine hemagglutinin antigen (HA), the National Institute for the Control of Pharmaceuticals and Biological Products in Beijing, drawing on its experience with H5N1, developed a temporary reference. "If [the Chinese lab] was wrong, it would have been a waste of time," says Yang. When WHO released its standard reagent in early August, "ours matched almost exactly," Yang says. That saved another month.

On 21 July, Chen was the first person in China – perhaps in the world – to receive a novel H1N1 vaccine. The next day, China launched a clinical trial of three kinds of vaccine in 13,000 children and adults, testing preparations from all 10 companies as "a kind of internal control," says Liang Xiaofeng, director of the Chinese CDC's National Immunization Program. On 21 August, the health ministry announced that a single dose of inactivated split virus vaccine containing 15 micrograms of HA generated a robust antibody response in all age groups; a stronger effect was seen in adolescents and adults than in children under 12 and adults over 60.

Chinese flu experts are still debating "whether one shot is enough or not," says Liang Xiaofeng. Preliminary results from two Chinese vaccinemakers – Sinovac and Hualan – indicate that a second dose, delivered 3 or 4 weeks after the first, offers "very limited further improvement," but analysis is continuing, he says. A single 15-microgram dose of a similar vaccine made by CSL Biotherapies in Parkville, Australia, elicited ample antibody levels in 116 of 120 adults, CSL epidemiologist Michael Greenberg and colleagues reported last week in The New England Journal of Medicine. "It's hard to imagine what additional protection would be afforded by a second dose," says Greenberg. He cautions that his group's study was limited to adults, so "it remains to be seen what is needed for children," who for their first seasonal flu vaccination require two doses.

In mid-August, says Chen, a cross-agency panel advised the central government that with schools about to reopen, a large-scale outbreak was inevitable. On 7 September, the State Council ordered Chinese companies to produce at least 65 million vaccine doses by the end of 2009, Liang Wannian says.

Earlier this week, China began vaccinating doctors, nurses, border staff, and the roughly 200,000 soldiers and performers who will take part in celebrations at Tiananmen Square on 1 October to mark the 60th anniversary of modern China's founding. In the coming days, the campaign will begin in primary and secondary schools. Liang Wannian acknowledges that China can vaccinate only a fraction of its roughly 200 million school-age children. "But if you can get 30% of the population," he says, "the severe epidemic will be greatly mitigated." Longini disagrees. To tamp down pandemic H1N1 into something resembling mild seasonal flu is likely to require about 70% vaccine coverage, he and colleagues predicted in a paper published online last week in Science.

Vulnerable groups – pregnant women and individuals with chronic respiratory illness or cardiovascular disease, for example – will also have priority, although Liang Wannian worries that in China "pregnant women are not very keen to accept the vaccine." He says China is "closely observing" a vaccine trial in pregnant women launched last week in the United States.

Thanks to a greatly enhanced flu-surveillance network, China plans to first focus its vaccination campaign on harder-hit regions: Shanghai and the Pearl River delta of southern China, which has three teeming cities – Guangzhou, Hong Kong, and Macau – in close proximity. In the delta and in Shanghai, China's business hub and a major port of entry, more than 30% of influenza-like illnesses are caused by pandemic H1N1, compared with a few percent in other parts of China. (The percentage currently exceeds 90% in the United States.) Vaccinating first in the delta, Shanghai, and the capital, Beijing, "will build up a barrier of immunity among the population and reduce the risk to other regions," says Liang Wannian. If that barrier holds, Chen insists, "we can keep the situation under control."

Swine flu 'could kill millions unless rich nations give £900m'

The Guardian, 20 September 2009, 00.08 BST
https://www.theguardian.com/world/2009/sep/20/swine-flu-costs-un-report

UN report says pandemic may result in anarchy unless western world pays for antiviral drugs and vaccines

The swine flu pandemic could kill millions and cause anarchy in the world's poorest nations unless £900m can be raised from rich countries to pay for vaccines and antiviral medicines, says a UN report leaked to the Observer.

The disclosure will provoke concerns that health officials will not be able to stem the growth of the worldwide H1N1 pandemic in developing countries. If the virus takes hold in the poorest nations, millions could die and the economies of fragile countries could be destroyed.

Health ministers around the globe were sent the warning on Thursday in a report on the costs of averting a humanitarian disaster in the next few months. It comes as officials inside the World Health Organization, the UN's public health body, said they feared they would not be able to raise half that amount because of the global downturn.

Gregory Hartl of WHO said the report required an urgent response from rich nations. "There needs to be recognition that the whole world is affected by this pandemic and the chain is only as strong as its weakest link. We have seen how H1N1 has taken hold in richer nations and in the southern hemisphere. We have been given fair warning and must act soon," he said.

The report was drawn up by UN officials over the last two months. It was commissioned in July after Ban ki-moon, the UN's secretary general, expressed concern that the H1NI virus could have a severe impact on the world's poorest countries.

It paints a disastrous picture for the world's most vulnerable people unless there is immediate action. "There is a window in which it will be possible to help poor countries get as ready as they can for H1N1 and that window is closing rapidly," it says.

"Countries where health services are overburdened by diseases, such as HIV/Aids, tuberculosis and malaria, will have great difficulty managing the surge of cases. And if the electricity and water sectors are not able to maintain services, this will have serious implications for the ability of the health sector to function.

"If suppliers of fuel, food, telecommunications, finance or transport services have not developed plans as to how they would continue to deliver their services, the consequences could be significantly intensified," it adds.

The 47-page report provides a detailed breakdown of the basic needs of 75 vulnerable countries with the weakest capacity to withstand an escalation of the virus. Six countries from Latin America, including Cuba and Bolivia, 21 countries from Asia and the Pacific such as North Korea and Bangladesh, and 40 countries from Africa such as Congo and Eritrea are included in the survey.

UN officials say in the report that £700m should be spent on antiviral drugs and vaccines to protect health care workers and other essential personnel as well as cover those suffering from severe illness. They have identified 85 countries that do not have the ability to access vaccines from any other source and intend to cover 5-10% of each population.

A further £147m should be put aside to organise vaccine campaigns, improve communications, monitor levels of illness and improve laboratory capacity in 61 countries, the report claims. The remainder should be used to pay for the WHO and other UN-related organisations to help in these countries as well as an emergency fund for additional antiviral medicines, it argues.

The UN's efforts were boosted last week when nine countries, including Britain and the US, pledged to give the equivalent of a 10% share of their swine flu vaccine supply to help fight the deadly virus's global spread. In Britain, Douglas Alexander, the development secretary, pledged to give £23m.

Some officials within WHO believe, however, that this will not be enough. One said that richer countries were reluctant to pay out all of the money that was needed. "The downturn means that governments countries are reluctant to give," he said.

Another said: "The money is a trickle, not a flood. It is going to be a struggle. If we are not careful, the virus could destroy a burgeoning economy or democracy."

The UN's request for the money comes as the virus begins to establish itself in some of the world's most vulnerable countries. On Wednesday, health officials told one website that the African continent had recorded 8,187 confirmed cases of swine flu and 41 deaths.

Swine flu was declared a pandemic in June and has since been identified in 180 countries. Pandemic experts believe that the western world, including Britain, is facing a second wave of the virus.

Benefit and Doubt in Vaccine Additive

The New York Times, 21 September 2009
https://web.archive.org/web/20201109030053/https://www.nytimes.com/2009/09/22/health/22vacc.html

Are Americans obligated to use an unproven vaccine to help protect people in other countries from the flu pandemic?

That is the crux of a debate over adjuvants – a class of substances that somewhat mysteriously increase the potency of vaccines. Early studies suggest that adjuvants (pronounced AD-joo-vants) could allow four times as many people to be immunized against the H1N1 pandemic influenza with a given amount of vaccine. So with the world facing possibly severe shortages of vaccine, the World Health Organization and some health experts have been calling for the use of adjuvants to stretch the vaccine supply.

"We have always argued that using adjuvanted vaccine would leave more vaccine for poor people," said Marie-Paule Kieny, director of the World Health Organization's initiative for vaccine research.

Wealthy nations have contracted for much of the expected pandemic vaccine production, leaving little for poorer countries. But while Canada and some European nations will use vaccines containing adjuvants, American officials have decided against it for now. They say that they have enough vaccine and that the safety of the additives has not been proved.

"These are products that potentially can be given to millions of healthy people," said Dr. Jesse Goodman, chief scientist at the Food and Drug Administration. "There is not a known, specific safety danger or issue" with the adjuvants, Dr. Goodman acknowledged. "There's just more uncertainty."

Officials also fear that using an adjuvant would raise public fears about vaccine safety at a time when their challenge might be about to shift from procuring enough vaccine to persuading people to use it.

"If you add what the public would perceive as another unknown there, there's a concern that people would be reluctant to get vaccinated," said Dr. Anthony S. Fauci, director of the National Institute of Allergy and Infectious Diseases.

Furthermore, officials say, one reason to use adjuvants is that they can increase a vaccine's potency against a virus to which it is poorly matched. But the swine flu vaccine is well matched to the virus, which has not mutated.

In the last two weeks, new data has lifted some of the pressure on the government to use adjuvants. Early studies suggest that even without an adjuvant, a single injection of swine flu vaccine – rather than the two anticipated – will confer adequate protection on adults and children at least 10 years old. That effectively doubles the number of people who can be immunized, and last week the government said it would make 10 percent of its roughly 200 million vaccine doses available to other countries. Eight other nations are also releasing some vaccine.

Still, Dr. Tadataka Yamada, president of the global health program at the Bill and Melinda Gates Foundation, said that most of the world's population of six billion people, mostly in poorer countries, would still be without vaccine, especially early in the pandemic.

Less vaccine than expected has been produced so far because of manufacturing problems. "Over all, there is still clearly a shortage of vaccine supplies," said Dr. Andrin Oswald, chief executive of the vaccine business at Novartis. Except for the United States, Dr. Oswald said, most countries ordering from Novartis have taken vaccine with adjuvant.

Dr. Kieny, of the W.H.O., said as many as three billion doses of vaccine could be produced in a year. But she said governments that had ordered adjuvant vaccines should not abandon them. "There's no reason to think these vaccines will not be safe," she said.

Even if adjuvants do not save the day in this pandemic, experts say they will become increasingly important for vaccines against all manner of diseases.

That is because many vaccines now being developed "simply don't work that well without an adjuvant," said Dr. Thomas Monath, acting chief medical officer of Juvaris BioTherapeutics, a company developing adjuvants.

Vaccines once typically contained a weakened or killed pathogen to spur an immune response. Some newer vaccines consist of only proteins or protein fragments from a pathogen, which makes them purer, safer and quicker to produce. But it turns out that the missing parts of the pathogens help to jolt the immune system; without them, an adjuvant is needed. Companies and academic laboratories are racing to develop adjuvants, "mainly because everyone recognizes the adjuvant could be the make-or-break component of a vaccine," Dr. Monath said.

Intercell, an Austrian company, is developing an adjuvant for flu shots in a patch worn on top of the injection site for a few hours.

Scientists are also learning how adjuvants work and how to devise them rationally rather than by trial and error.

"For the longest time, adjuvants were sort of a witch's brew of substances, empirically designed," said Bali Pulendran, a professor of pathology at Emory University. "What was once a black box is now being illuminated at the mechanistic level by new advances in immunology."

The term adjuvant, from a Latin word meaning "to help," was coined in the 1920s by Gaston Ramon, a veterinarian at the Pasteur Institute in France, who observed that horses given diphtheria toxin had a stronger immune response if they had some inflammation at the injection site. Among his first adjuvants were bread crumbs and tapioca.

Within a few years, scientists discovered that aluminum salts could prompt an immune response. Alum, as this adjuvant is often called, is now used in various vaccines, including those for tetanus and hepatitis B. It is a relatively weak adjuvant. But about 80 years after its discovery, it is still the only one used in vaccines the United States.

That could soon change. An advisory committee to the F.D.A. recently recommended approval of Cervarix, a vaccine against the virus that causes cervical cancer. The vaccine, made by GlaxoSmith Kline, uses an adjuvant containing a bacterial lipid. (Gardasil, the Merck cervical cancer vaccine already in use, has an aluminum adjuvant.)

Alum is not used in flu shots because it has little effect. But Novartis and GlaxoSmithKline are selling pandemic flu vaccines containing newer adjuvants they have developed. They are oil-in-water emulsions of squalene, a lipid that is found in the body. Glaxo's also contains vitamin E.

A seasonal flu vaccine containing Novartis's MF59 adjuvant has been used in Europe since 1997. Glaxo's adjuvant, called AS03, is in a vaccine approved in Europe for use against the H5N1 bird flu, which spurred fears of a pandemic a few years ago.

For the bird flu, an adjuvant was crucial because vaccines without adjuvants did not work well in tests and required huge doses. Glaxo's vaccine required only one twenty-fourth as much antigen, the viral component of the vaccine, as another company's vaccine that did not contain an adjuvant.

Thinking the swine flu might pose the same problem, federal officials ordered $700 million worth of adjuvant from Novartis and Glaxo.

If the adjuvants were used, they would have to be combined with the vaccine before the injection was given. And because the adjuvants have not been approved by the F.D.A., they would fall under a so-called emergency use authorization.

But in the last two weeks it has been learned that the vaccines against the H1N1 virus stimulate a strong response on their own. A single shot containing 15 micrograms of antigen – the same amount used for each strain in a seasonal flu vaccine – should confer adequate protection for most people.

Preliminary data from GlaxoSmithKline show that a vaccine with an adjuvant might use only one-fourth as much antigen. But federal officials say the savings are not large enough to offset the possible risks and extra complexity of using the adjuvants.

While adjuvants tend to increase the temporary pain, swelling or fatigue caused by a vaccine, the main concern is whether they might cause an autoimmune disease, like rheumatoid arthritis, in which the immune system attacks the body’s own tissues. Some animal studies have suggested that possibility.

Last year, the F.D.A. halted a clinical trial of a hepatitis B vaccine containing a novel adjuvant after one participant developed a type of blood-vessel inflammation that is considered an autoimmune disease. But the agency lifted its hold this month, apparently satisfied that the vaccine, made by Dynavax Technologies, was not the cause.

Adjuvant makers say there is no cause for concern with the flu vaccines. Dr. Bruce Innis, head of the clinical flu vaccine team at GlaxoSmithKline, said the immune response spurred by his company’s adjuvant was directed only at the antigen in the vaccine. "There is not a general upregulation of immune responses across the body," which would be needed for an autoimmune disease, Dr. Innis said.

Novartis says more than 40 million doses of vaccine with its adjuvant have been used in Europe, with no signs of problems. But Dr. Fauci, of the National Institute of Allergy and Infectious Diseases, said Novartis’s adjuvant had been used mainly among the elderly, who tended to have weaker immune systems. There is less data, he said, on its use among children, younger adults and pregnant women.

H1N1 FluMist ~ the Nasal Spray that Keeps on Giving!

Associated Content, 23 September 2009
https://web.archive.org/web/20091023091136/http://www.associatedcontent.com/article/2205843/h1n1_flumist_the_nasal_spray_that_keeps.html?cat=70 (link is corrupted)

Everyone has to be responsible for their own decisions. If you are afraid of catching the H1N1 flu this year. You may be pondering whether to get a flu shot or using the H1N1 FluMist. The FluMist is administered into your nostrils. Before making your final decision, you may want to ask some questions and think of some consequences to taking the H1N1 FluMist nasal spray.

The H1N1 FluMist is made with "live" virus. This means that the H1N1 flu will be a part of the nasal spray formula. It's supposed to be just enough to start your immunity to build defenses to it. The shot is supposed to be a killed virus.

If you take the H1N1 FluMist, you will in fact become a carrier of the H1N1 flu. Information on this drug states that *you can and will shed the virus for up to 21 days*. That means as you are visiting with your elderly family members, or shopping in the isles of your grocery store or sitting in church with young children and people with immune problems, YOU are going to be shedding the virus H1N1 germs.

If you are a person that cannot tolerate the shot or the FluMist for the H1N1 flu, you are a sitting duck when it comes to being around people who have taken the FluMist. The use of FluMist is for people ages 2 - 49. How many people do you come into contact each day that don't fit the age range?

Drugs.com says that you should be careful when coming into contact with "FluMist with anyone who has a weak immune system caused by disease (such as cancer, HIV, or AIDS), or by certain medicines such as steroids, cancer chemotherapy, or radiation treatment. A person with a weak immune system can become ill if they have close contact with you after you have recently received a an influenza vaccine." Pregnant women are also on this list of people who should NOT use FluMist.

What happens when anything gets in your nose? You sneeze! Please be a responsible user of the FluMist and cover your face when you sneeze and cough. Remember, you are passing the H1N1 flu germs. The flu is passed from person to person with the sneezing, the coughing and germs from your hands. So if you take FluMist for the H1N1 flu, please practice good hygiene for the rest of us and wash, wash, wash your hands! => the next page is blocked

Information for a Healthy New York

Mandatory Flu Vaccine for Health Care Workers

Department of Health, New York, 24 September 2009
https://web.archive.org/web/20090928023749/http://www.health.state.ny.us/press/releases/2009/2009-09-24_health_care_worker_vaccine_daines_oped.htm

Commissioner Tells Health Care Workers: Mandatory Flu Vaccine is in the Best Interest of Patients and Workers.

Albany, N.Y. (Sept. 24, 2009) - State Health Commissioner Richard F. Daines, M.D., today released this open letter to health care workers in New York State:

As health care workers, we share one of the proudest traditions of all professions: we put our patients' interests ahead of our own.

As a physician who spent more than 20 years working in hospitals, I had the honor of working side by side with other physicians, nurses, food service workers, technicians and transporters in the early and uncertain months of what would become the HIV epidemic, in those first confused days of the anthrax attacks, and when any new international traveler with a fever might have been carrying SARS. Never once, no matter what our private fears might have been, did we shirk from our duties or put personal anxieties ahead of the interests of our patients. We took the recommended precautions, worked carefully and cautiously, and gave our patients the compassionate and selfless care for which our professions and institutions are rightly given a special place in our society.

In furtherance of that tradition, on August 13th the New York State Hospital Review and Planning Council adopted a regulation recommended by the New York State Health Department making approved annual influenza vaccinations mandatory, unless medically contraindicated, for health care workers in hospitals, outpatient clinics and home care services. Legislation applying the same standards to nursing home workers has also been proposed. The new regulation will apply first to the routine annual seasonal influenza vaccine now available. With the recent FDA approval of the vaccine for novel H1N1 flu ("swine flu"), the regulation will also apply to that vaccine, just in time for the second wave of novel H1N1 influenza already returning this fall.

Questions about safety and claims of personal preference are understandable. Given the outstanding efficacy and safety record of approved influenza vaccines, our overriding concern then, as health care workers, should be the interests of our patients, not our own sensibilities about mandates. On this, the facts are very clear: the welfare of patients is, without any doubt, best served by the very high rates of staff immunity that can only be achieved with mandatory influenza vaccination – not the 40-50% rates of staff immunization historically achieved with even the most vigorous of voluntary programs. Under voluntary standards, institutional outbreaks occur every flu season. Medical literature convincingly demonstrates that high levels of staff immunity confer protection on those patients who cannot be or have not been effectively vaccinated themselves, while also allowing the institution to remain more fully staffed.

Throughout this fall and winter, more patients than ever may enter our hospitals and clinics without effective influenza immunity. Some will be too young or have other contraindications to vaccination or will have failed to receive vaccinations for a variety of reasons. Others will be too

frail for vaccination to be effective. Large numbers of people quite clearly would like to take the new H1N1 vaccine as soon as it is available but will be denied that opportunity because they do not fall into one of the first prioritized groups. For all of these individuals, safety lies in being treated in institutions and by health care personnel with the nearly 100% effective immunity rates seen with other long-mandated vaccinations for health care workers, such as measles and rubella.

In recognition of health care's noble tradition of putting patients' interests first and understanding the need to keep our health care system functioning optimally during this challenge, federal authorities made a remarkable decision regarding the first groups to be given access to the new H1N1 vaccine. In addition to giving highest priority for the new vaccine to those who would receive the direct or personal benefit – pregnant women, caregivers to infants, children and the chronically ill – authorities declared that health care workers would also be given earliest access to the vaccine, ahead of millions of other individuals who have roughly equal or even higher risks of contracting H1N1 influenza with all the discomfort or worse that could mean for them as individuals.

Knowing that our privileged access to the new vaccine is earned not by our personal risk factors but by the special trust society places in us, then how can we as health care workers maintain that our cooperation in protecting the most vulnerable members of society is nevertheless optional? Without mandated vaccinations, many ethically troubling situations may occur. A health care worker unconcerned about "ordinary flu" might refuse the routine seasonal vaccine, but then expect to be in the front of the line for the "good stuff" – the new and strictly rationed swine flu vaccine. Institutions may find themselves short staffed and less than fully capable if their workers fail to get the seasonal influenza vaccine but then proceed to consume hundreds of doses of the new vaccine, therefore denying those doses to other groups. This scenario will certainly not achieve the staff-wide immunity levels needed to assure patient safety and optimal staffing – the very reasons for which health care workers received their priority in the first place.

Influenza vaccination has saved thousands upon thousands of lives over the last three decades, and thousands more could have been saved if the vaccinations had been more widely used. This year, through effective use of vaccination, we have perhaps the best opportunity to save lives and keep our society and institutions running more smoothly than we have had in 50 years or more. This is not the time for uninformed or self-interested parties to attempt to pump air into long-deflated arguments about vaccine safety in general or to use a single 33-year-old episode to deny decades of safety and saved lives achieved by influenza vaccines prepared in the same way as this year's formulations.

The seasonal influenza vaccine has completed, and before its approval the new H1N1 vaccine also underwent, the most careful development, production and testing processes leading scientists, clinicians and public health authorities can devise. Approval of the H1N1 vaccine was based on the application of the same scientific standards and methods that we believe should govern all our health care practices. We, as health care workers, owe it to our patients and to society in general to demonstrate our confidence in those scientific standards. Even more importantly, we should reconfirm our noble commitment to the tradition of putting patients' interests first by supporting the mandatory influenza vaccination requirement.

EU agency recommends first two H1N1 flu vaccines

Reuters, 25 September 2009, 10:55 PM GMT+8
https://www.reuters.com/article/us-flu-vaccine-europe/eu-agency-recommends-first-two-h1n1-flu-vaccines-idINTRE58O1UB20090925/

London (Reuters) – European healthcare regulators recommended two swine flu vaccines for approval on Friday, clearing the way for mass vaccination programs to start imminently.

Governments and manufacturers have been scrambling for vaccines to target the new H1N1 flu strain, ahead of a feared second wave of infection as the northern hemisphere heads into winter.

The European Medicines Agency (EMEA) said its expert committee on new drugs gave the go-ahead for the first H1N1 swine flu vaccines from GlaxoSmithKline and Novartis, called Pandemrix and Focetria.

The shots now only need final approval from European Commission, a move EMEA chief executive Thomas Lonngren said he expected to happen "very rapidly ... hopefully next week" as part of an accelerated regulation system for pandemic vaccines.

A third vaccine from Baxter, which had also been submitted under the fast-track "mock-up" procedure, did not get a green light, but the watchdog said it was still reviewing this and other applications.

A spokeswoman for Baxter said it expected to receive a positive opinion "within days."

Shares in Glaxo rose 1.7 percent by 1350 GMT, buoyed by the European green light.

"They weren't first out of the gate with the other players in the U.S. -- although they are confident of getting approval there – so this has given them a bit of boost," said Navid Malik, an industry analyst at Matrix Corporate Capital.

Baxter stock added 1.2 percent, while Novartis was flat.

The World Health Organization (WHO) said on Thursday that drugmakers will only be able to produce enough H1N1 vaccine each year for half the planet - around 3 billion doses per year – meaning governments will have to decide who should get the limited supplies.

The WHO added that a single dose should be enough to give immunity to healthy adults and older children from the virus commonly known as swine flu, which was declared a pandemic in June.

Two doses...for now

The EMEA, however, said it was currently recommending two doses be given, at an interval of three weeks, although it acknowledged preliminary data suggested one dose might suffice and this recommendation could be updated as new data comes in.

The London-based watchdog said it was confident the new vaccines were safe, despite being rushed through the approval process, adding manufacturers would have to carry out safety studies in 9,000 subjects for each vaccine after launch.

"Decades of experience with seasonal influenza vaccines indicate that insertion of a new strain in a vaccine should not substantially affect the safety or level of protection offered," the agency said in a statement.

Both the Glaxo and Novartis shots contain adjuvants -- substances that enhance the immune response so that less active ingredient, or antigen, can be used in each dose.

Glaxo said its vaccine contained just 3.75 micrograms of antigen while the Novartis product contains 7.5 micrograms. That compares with 15 micrograms needed in non-adjuvanted vaccines.

Most rich nations have contracts with drugmakers to obtain enough vaccine to cover their populations and governments have already been building up stockpiles ahead of the shots winning regulatory approval.

But poorer countries lack the financial resources to compete for an early share of limited supplies.

Earlier this month, America's Food and Drug Administration (FDA) approved H1N1 flu vaccines from four drugmakers – Sanofi-Aventis, CSL, AstraZeneca's MedImmune unit and Novartis.

The WHO says it will begin an initial distribution of around 300 million doses of H1N1 vaccine donated by rich nations to more than 90 developing countries from November.

Anthrax Vaccine -- posts by Meryl Nass, M.D.

Meryl Nass

Hospitals and States Mandating Swine Flu Vaccinations Don't Get it
They will be on the Hook for all Liability for Injured Recipients

Anthrax Vaccine, 26 September 2009
http://anthraxvaccine.blogspot.com/2009/09/hospitals-and-states-mandating-swine.html

A domino effect is cascading through the country, as officials rush to impose vaccination mandates on citizens (Massachusetts) and health care employees (New York), as well as mandate influenza (seasonal +/-swine) vaccinations in many other healthcare systems and hospitals. Many state laws are written such that in a declared emergency, vaccination or, alternatively, quarantine are required. The tsunami mandating vaccinations (see WaPo article) is occurring in a vacuum of information about the incidence and impact of the diseases citizens will be forcibly protected against, and the effectiveness and safety of mandated vaccines. Meantime, the institutions mandating the vaccinations appear clueless about the massive liability for vaccine injuries they are assuming as a result of these mandates.

1) Low disease incidence of seasonal influenza viruses

Currently (this week) only 1% of circulating influenza viruses in the United States are of the "seasonal" type. Seasonal flu outbreaks usually start late in the season: November at the earliest. It takes 7-10 days to develop a strong immune response. Vaccine recipients who are elderly or have weak immune systems have a rapid decline in antibody levels over the few months following vaccination. It makes no sense to vaccinate these people early in the season, as they may lose vaccine protection before flu season is over.

And since only 1% of currently circulating flu viruses will be covered by the seasonal vaccine, **it** hardly makes sense to use that vaccine at all, at this point in time. If such viruses increase in the population as time passes, vaccinations could be started later. (Those with good memories may recall that seasonal vaccinations are normally offered in October and November.)

2) Uncertain swine flu vaccine effectiveness and adverse effects

Swine flu vaccine generates good antibody levels, but we still don't know how well it prevents influenza disease. Nor do we know how safe it is, since pretty much all the experts agree that until millions receive a vaccine, it is impossible to accurately identify its adverse effects.

Now, a story out of British Columbia's Center for Disease Control indicates that people who have received flu vaccine in a previous year may be more susceptible to developing swine flu (the disease). Odd as this sounds at first, it is a fact that receiving certain animal vaccines *increased* susceptibility to the disease the vaccine was designed to prevent. Such vaccines were taken off the market.

Update: Most of Canada's provinces have suspended seasonal flu shots for those under 65 due to this study, since it suggests last season's flu shot enhances susceptibility to swine flu infection. Apparently Canada fears this year's seasonal flu shot may do so as well. But those over 65 are more susceptible to seasonal flu, and less susceptible to swine flu, than younger age groups, so they are the appropriate target group for seasonal flu vaccine.

We need to wait to learn if this finding (higher risk of swine flu associated with prior vaccination) is borne out by other studies, but it does offer a reminder that vaccinations can have unanticipated effects that are a lot more serious than a sore arm. By the way, CSL's swine flu "vaccine triggered [systemic] side-effects including headache, myalgia, fever and nausea in more than 60 per cent of trial participants."

From Bloomberg:

"This is the biggest mass vaccination we have done in world history and we are doing it on data so far which shows this virus is not a lot worse than seasonal influenza," said Peter Collignon, director of infectious diseases at the Australian National University's medical school. "There is a real worry that the fear makes us do things out of proportion to the risk."

"If this was causing 1 or 2 percent mortality and spreading quickly, I would be the first person up there with my arm," Collignon said. As it is, "I will put my arm up next February or March when I have seen more data."

Swine flu killed 170 people in Australia, and the epidemic peaked there in July: a far cry from predictions of many thousands of deaths. Now Australia plans to start swine flu vaccinations; but it is likely most of the population is already immune as a result of widespread exposure. (When Australians enrolled in swine flu vaccine trials, 30% of subjects were found to be immune already.)

3) Workplaces and states that mandate swine flu vaccinations *don't have liability waivers*

But everyone else involved in the swine flu vaccination process does have a liability waiver: this includes manufacturers, distributors, medical professionals who administer the vaccine and government program planners who worked on the vaccination program. Read it in the Federal Register of June 25, 2009.

It says that licensed individuals authorized to prescribe, administer and dispense the vaccine have liability waivers, but there are no other "qualified persons" (pursuant to section 319F-3[i][8][B]) who are given this immunity, (such as employers of these persons, or states). Unless there has been a new government declaration extending immunity to these entities since June 25, of which I am unaware, hospitals, other health care institutions and states appear to be inviting lawsuits as a result of employee or state mandates they are issuing.

Since the newly created federal compensation program for swine flu vaccine injuries has both a low payment cap and prohibits access to the U.S. legal system, the occurrence of employee mandates virtually guarantees that any vaccine injuries suffered by employees will result in lawsuits against employers, the only "deep pocket" left liable.

It appears that some employers may have already dug themselves a hole by issuing blanket mandates, since some states guarantee vaccine exemptions on the basis of religious beliefs or union contracts.

4. Vaccine Mandates, Exemptions and Legal Implications

See this Congressional Research Service report on state provisions for vaccine exemptions. And this book chaper by Malone KM and Hinman AR, page 273 (current in 2001) for discussion on vaccine exemptions, constitutionality of mandates, and list of 48 states with religious exemptions and 15 with philosophic vaccine exemptions. Also see this 2008 ACLU Report by Annas G, Mariner WK and Parmet WE, titled "Pandemic Preparedness: The Need for a Public Health--Not a Law Enforcement/National Security--Approach." It "examines the relationship between civil liberties and public health in contemporary U.S. pandemic planning and makes a series of recommendations for developing a more effective, civil liberties-friendly approach." An excerpt:

"It is worth noting that federal legislation has given vaccine manufacturers immunity for the vaccines they produce in response to a public health emergency. The CDC has also called for broad immunity statutes to protect "first responders" and unlicensed health professionals who respond to emergencies. These proposals are viewed as a form of "Good Samaritan" statute, but should be resisted in the pandemic setting for at least three reasons:

(1) almost all of the people and corporations covered are not volunteers, but are doing a job that they have been trained for and are being paid for and **should be accountable and responsible for their actions**;

(2) negligent Samaritans are no good – they harm rather than help; and

(3) immunity [from liability] encourages negligent and intentional violations of individual rights that breeds public distrust."

The New York Times

Donald G. McNeil, Jr.

Don't blame flu shots for all ills, officials say

The New York Times, 27 September 2009
https://www.nytimes.com/2009/09/28/health/policy/28vaccine.html
https://web.archive.org/web/20111228010319/http://www.nytimes.com/2009/09/28/health/policy/28vaccine.html?_r=1

As soon as swine flu vaccinations start next month, some people getting them will drop dead of heart attacks or strokes, some children will have seizures and some pregnant women will miscarry.

But those events will not necessarily have anything to do with the vaccine. That poses a public relations challenge for federal officials, who remember how sensational reports of deaths and illnesses derailed the large-scale flu vaccine drive of 1976.

This time they are making plans to respond rapidly to such events and to try to reassure a nervous public – and headline-hunting journalists – that the vaccine is not responsible.

Every year, there are 1.1 million heart attacks in the United States, 795,000 strokes and 876,000 miscarriages, and 200,000 Americans have their first seizure. Inevitably, officials say, some of these will happen within hours or days of a flu shot.

The government "is right to expect coincident deaths, since people are dying every day, with or without flu shots," said Dr. Harvey V. Fineberg, president of the Institute of Medicine and co-author of "The Epidemic That Never Was," a history of the 1976 swine flu vaccination campaign.

Officials are particularly worried about spontaneous miscarriages, because they are urging pregnant women to be among the first to be vaccinated. Pregnant women are usually advised to get flu shots, because they and their fetuses are at high risk of flu complications, but this year the pressure is greater. Expectant mothers are normally advised to avoid drugs, alcohol and anything else that might affect a fetus.

"There are about 2,400 miscarriages a day in the U.S.," said Dr. Jay C. Butler, chief of the swine flu vaccine task force at the federal Centers for Disease Control and Prevention. "You'll see things that would have happened anyway. But the vaccine doesn't cause miscarriages. It also doesn't cause auto accidents, but they happen."

In the opening days of the 1976 vaccination campaign, which eventually vaccinated 45 million Americans, three elderly Pittsburgh residents died soon after receiving their shots at the same clinic. Though scientists believe it was just a freakish coincidence, some news reports suggested the vaccine had killed them.

"Press frenzy was so intense it drew a televised rebuke from Walter Cronkite for sensationalizing coincidental happenings," Dr. David J. Sencer, who was then the director of the C.D.C., wrote in 2006 reflections on the vaccination campaign.

Two months later, reports emerged of vaccine recipients suffering from Guillain-Barré syndrome, in which the body's immune system attacks the nerves, leading to temporary or permanent paralysis and, in a few cases, death. That effectively ended the campaign, as officials suspended it to investigate. Experts still disagree over whether the vaccine caused cases to increase that year, and the C.D.C. will be on high alert for reports of it this year.

Guillain-Barré's cause is unknown, though different studies have suggested it more often affects people who have had a flu shot, the flu itself, some bacterial infections – or even, according to Dr. Sencer's paper, people who have been struck by lightning.

In any case, after the suspension, there was no reason to restart because the predicted swine flu epidemic never emerged.

That, experts emphasize, is the great difference between 1976 and 2009. The earlier virus apparently burned out the previous winter inside Fort Dix, N.J., before any vaccine was even made, while this pandemic H1N1 virus has already infected millions and, unchecked, will probably reach over two billion, according to the World Health Organization.

In 1976, getting flu shots into 45 million Americans was unprecedented. Now about 100 million get annual shots, and the government has ordered twice that many doses of swine flu vaccine.

Other changes since 1976 worry officials. The 24-hour cycle of news on television and the Internet did not then exist; public health officials now must be ready to respond to rumors instantly. In 1976, the C.D.C. did not hold news conferences, and it took it five days to respond to the Pittsburgh deaths, Dr. Fineberg said.

"Back then, it was a neat thing to have a fax machine and get out four pages a minute," said Joe Quimby, a press officer for the disease centers. "Now, communications have to be multimodal. Turning on the three broadcast news outlets is not going to reach everybody any more."

The agency now has a "war room" in its Atlanta headquarters and, since the pandemic began in April, has held news conferences, sometimes even daily, at which reporters from around the world ask questions by phone. They can be seen live on the agency's Web site, and it has another Web site, flu.gov, devoted to the pandemic, as well as a constantly updated Facebook page and Twitter feed.

Complicating the challenge for officials, some experts argue, is that health news coverage has suffered since 1976.

"I've seen the rise and fall of experienced medical reporters," said Dr. Michael T. Osterholm, director of the Center for Infectious Disease Research and Policy at the University of Minnesota. "I can't tell you how many reporters have come to me since last spring who don't really know what flu is."

Also, antivaccine activists are far more powerful now. Thirty-three years ago, vaccines were enthusiastically welcomed; many parents or grandparents still remembered children dead of smallpox, measles or polio. The minority opposing them were often followers of natural healing or traditional chiropractic beliefs.

In 1976, autism was not on the public's mind, and the problem was still attributed to indifferent mothering. Vietnam veterans with chronic illnesses usually blamed Agent Orange, a defoliant.

Today, many parents blame vaccines for their children's autism and some ill Gulf War veterans blame their anthrax shots.

Some antivaccine groups are raising fears of thimerosal, a preservative used in some brands of flu vaccine. Others issue dire warnings about squalene, an immune booster used in military vaccines and in some European flu vaccines but not in any American ones.

And, in the rancor over health insurance reform, unfounded rumors are spreading that the Obama administration will make swine flu shots mandatory. Administration officials have emphatically denied that. But a recent decision by New York State to make them mandatory for all hospital employees has reinvigorated those rumors on the Internet.

To defend itself, Dr. Butler said, the C.D.C, has compiled data on how many problems like heart attacks, strokes, miscarriages, seizures and sudden infant deaths normally occur. And it has broken those figures down for various high-priority vaccine groups, like pregnant women or children with asthma. When vaccinations begin, it plans to gather reports from vaccine providers, hospitals and doctors, looking for signs of adverse events, so it can detect problems before rumors grow.

"Then we'll try to verify the signal, see if it's real," Dr. Butler said. "Then we'll try to see if it's associated with the vaccine. If it is, we'll say so. The process will be as transparent as we can make it."

The Washington Post

Authorities Respond to H1N1 With Post-Vaccine Monitoring

The Washington Post, Associated Press, 28 September 2009

https://web.archive.org/web/20150905092027/http://www.washingtonpost.com/wp-dyn/content/article/2009/09/27/AR2009092702913.html
https://web.archive.org/web/20100105175227/http://www.washingtonpost.com/wp-dyn/content/article/2009/09/27/AR2009092702913_2.html

Kathleen Sebelius, HHS chief, talks with Mayo Clinic vaccine expert Gregory Poland, center, and David Tayloe of the American Academy of Pediatrics. (By Luis M. Alvarez -- Associated Press)

More than 3,000 people a day have a heart attack. If you're one of them the day after your swine flu shot, will you worry that the *vaccine was to blame and not the more likely culprit, all those burgers and fries*?

The government's system to track possible side effects of mass flu vaccinations will begin next month, aimed at detecting any rare but real problems quickly, and explaining the inevitable coincidences that are sure to cause some false alarms.

"Every day, bad things happen to people. When you vaccinate a lot of people in a short period of time, some of those things are going to happen to some people by chance alone," said Daniel Salmon, a vaccine safety specialist at the Department of Health and Human Services.

Health authorities hope to vaccinate more than half of the population in just a few months against swine flu, which doctors call the 2009 H1N1 strain. Vaccination is voluntary, and how many get it depends partly on confidence in its safety.

"*The recurring question is, 'How do we know it's safe?'* " said Gregory Poland of the Mayo Clinic.

Enter the intense new monitoring. On top of routine vaccine tracking, there are these government-sponsored projects:

- Harvard Medical School scientists are linking large insurance databases that cover as many as 50 million people with vaccination registries around the country for real-time checks of whether people see a doctor in the weeks after a flu shot and why. The huge numbers make it possible to quickly compare rates of complaints among the vaccinated and unvaccinated, said the project leader, Richard Platt, Harvard's population medicine chief.

- Johns Hopkins University will direct e-mails to at least 100,000 vaccine recipients to track how they're feeling, including the smaller complaints that wouldn't prompt a doctor visit. If anything seems connected, researchers can call to follow up with detailed questions.

- The Centers for Disease Control and Prevention is preparing take-home cards that tell vaccine recipients how to report any suspected side effects to the nation's Vaccine Adverse Event Reporting system.

"*We don't have any reason to expect any unusual problems with this vaccine*," said Neal Halsey, director of Hopkins's Institute for Vaccine Safety, who is directing the e-mail effort.

Health authorities will have to tell quickly if there seem to be more cases of a particular health problem than usual. So the CDC is racing to compile a list of what's normal: 25,000 heart attacks every week; 14,000 to 19,000 miscarriages every week; 300 severe allergic reactions called anaphylaxis every week.

Any spike would trigger a quick investigation to see whether the vaccine increases risk and by how much, so health officials could issue warnings.

Very rare side effects by definition could come to light only after large-scale inoculations begin -- making this the year scientists may finally learn whether flu vaccine is linked to Guillain-Barr? syndrome, an often reversible but sometimes fatal paralysis. It sometimes occurs after viral infections.

But the vaccine concern stems from 1976, when 500 cases were reported among the 45 million people vaccinated against that year's swine flu. Scientists never were able to prove that the vaccine increased the risk. The CDC maintains that if the seasonal flu vaccine is related, the risk is no more than a single case per 1 million vaccinated.

However the flu season turns out, the extra vaccine tracking promises a lasting impact.

"Part of what we hope is that it will teach us something about how to monitor the safety of all medical products quickly," said Harvard's Platt.

CBCnews.ca

Swine flu vaccine may be mandatory for soldiers in Afghanistan

CBC News, The Canadian Press, 28 September 2009, 5:05 PM EDT
https://www.cbc.ca/news/canada/swine-flu-vaccine-may-be-mandatory-for-soldiers-in-afghanistan-1.835532

The Canadian Forces reserves the right to order its soldiers deployed in Afghanistan to take the vaccine meant to prevent swine flu, says the military's surgeon general.

But Commodore Hans Jung said it would be an order of last resort that will need to be studied to ensure it doesn't violate the Charter of Rights and Freedoms.

Just how far the military can go in ordering illness-prevention measures is a sensitive topic given the bruising legal fights almost a decade ago over anthrax injections.

The current plan is to make the H1N1 vaccine, expected to be available in November, voluntary for soldiers, sailors and aircrew throughout the Canadian Forces, including those on duty in Kandahar and elsewhere around the world.

But the nightmare scenario of an army laid up with the flu isn't far from minds of commanders.

"The option of mandatory (injections) is a hip-pocket issue. It's a card that would be played in a truly dire circumstances," Jung said in a recent interview with The Canadian Press.

"We're going to be strongly recommending that everybody take the vaccine offered. Obviously depending on how the pandemic evolves in Canada and around the world, the government and the military may have to think about" ordering soldiers to take it.

Anthrax shots violated soldiers' rights

Jung said the chief of defence staff, the country's top military commander, has the necessary legal authority to make it happen, as seniors commanders did during the 1990s, when troops, sailors and air crew heading to the Middle East were required to take anthrax vaccinations.

Those who refused were brought up on disciplinary charges and faced courts martial.

The practice of mandatory anthrax injections, which made some soldiers sick and raised fears among them of Gulf War Syndrome, ended in 2000 on the orders of military judge Col. Guy Brais.

He ruled the program was violation of a soldier's constitutional rights.

Jung took over as surgeon general and head of the military's health branch in the summer.

He said the possibility of a swine flu pandemic, with an army fighting in the field, presents National Defence and the military's health services branch with a unique challenge. He described the policy as being in "evolution."

There is growing public skepticism about the H1N1 vaccine. Canada has ordered more than 50 million doses from GlaxoSmithKline.

For military members stationed at home, the system of immunization isn't much different from that for ordinary citizens.

H1N1 not mandatory, for now

Health Canada officials have repeatedly stressed that the swine flu vaccination will not be mandatory for Canadians, and Jung said that includes members of the military.

But overseas it's a different matter, where the army's health services branch has set a goal of voluntarily immunizing between 60 and 70 per cent of the roughly 2,850 Canadians serving in Kandahar.

Jung said if they don't get that figure and the flu is severe, commanders would have to look at a mandatory system.

One of the complicating factors is that Canadian troops share the airfield with more than 15,000 other NATO troops and patrol through regions where Afghans have little access to basic medical care and sanitation.

Jung said he's confident they'll get enough volunteers and said much depends on the severity of the anticipated second wave.

The military is watching the computer simulations on the potential spread H1N1. The contingency plans at National Defence range from those for a mild outbreak, similar to the seasonal flu, all of the way up to aiding civil authorities in the event of am outbreak as serious as the 1918-19 Spanish flu, which is estimated to have killed at least 21 million people around the globe.

Infection Control TODAY®

AMA Creates New CPT Codes for H1N1 Flu Immunizations

Infection Control, 28 September 2009
https://www.infectioncontroltoday.com/view/ama-creates-new-cpt-codes-h1n1-flu-immunizations

With both seasonal influenza and H1N1 influenza circulating this flu season, the American Medical Association (AMA) today announces it has expedited the publication of a new code specific to vaccine administration and revised existing code 90663 to include the H1N1 vaccine.

The new Current Procedural Terminology (CPT) code issued by the AMA will streamline the reporting and reimbursement procedure for physicians and healthcare providers who are expected to administer nearly 200 million doses of the H1N1 vaccine in the United States. The codes will also help to efficiently report and track immunization and counseling services related to the H1N1 vaccine throughout the health care system.

In consultation with the U.S. Department of Health and Human Services, the AMA CPT Editorial Panel created code 90470 to report H1N1 immunization administration and counseling. Code 90663 was revised by the CPT Editorial Panel to refer specifically to the H1N1 vaccine product. Both, revised code 90663 and Category I CPT Code 90470 are effective immediately.

For quick reference, the two codes are:

90470–H1N1 immunization administration (intramuscular, intranasal), including counseling when performed

90663–Influenza virus vaccine, pandemic formulation, H1N1

The San Diego Union-Tribune

Lolita C. Baldor

Military to get mandatory swine flu shots soon

The San Diego Union-Tribune // The Associated Press, 29 September 2009, 2:52 PM PT
https://www.sandiegouniontribune.com/sdut-us-military-swine-flu-092909-2009sep29-story.html

Washington – U.S. military troops will begin getting required swine flu shots in the next week to 10 days, with active duty forces deploying to war zones and other critical areas going to the front of the vaccine line, a top military commander said Tuesday.

Air Force Gen. Gene Renuart also told The Associated Press that as many as 400 troops are ready to go to five regional headquarters around the country to assist federal health and emergency management officials if needed as the flu season heats up.

The Pentagon has bought 2.7 million vaccines, and 1.4 million of those will go to active duty military. National Guard troops on active duty are also required to receive the vaccine, as are civilian Defense Department employees who are in critical jobs.

As a result, the military is expected to provide health officials with an early assessment of the vaccine.

"Because I can compel people to get the shots, larger numbers will have the vaccine," said Renuart, commander of U.S. Northern Command. "They will, as a percentage of the population, be vaccinated more rapidly than many of us. So we may see some objective results, good or not, of the vaccinations."

thedoctorwithin

Tim O'Shea

Swine Flu Vaccine – October 2009
Licensed and Untested

The Doctor Within, 29 September 2009
https://web.archive.org/web/20091002215800/http://www.thedoctorwithin.com/swine/swine-flu-vaccine.php

This has been a big week for swine flu vaccines. With the money machine in full swing to get the untested swine flu vaccine out to the public ASAP, it's hard to keep up with the level of deception in mainstream media. But we'll give it a try.

Associated Press - 22 Sep 09

On 22 Sep 9, *Associated Press* ran the story "**Govt: 1 swine flu shot enough for older kids**" wherein they buried the lead: National Institutes of Health now wants to give four separate flu shots to kids younger than 9 years old. Two of the shots will be the brand new untested swine flu vaccines, and the other two will be the 'regular' flu shot.

Before we look at the direct misstatements of fact in that *AP* article, let's read it at face value. Here is some of the new 'information': [3]

National Institutes of Health director Fauci and CDC's Dr Schuchat do proclaim:
- children 9 and younger will need 2 flu shots and 2 swine flu shots
- everybody else will need 1 of each
- swine flu vaccine will be ready in October
- we'll have 251 million doses
- swine flu targets young children, which is why they need 2 shots
- they can get both shots the same day, one in each arm
- NIH has studies involving 600 children
- children 10 and older showed protection from the new vaccine
- younger children didn't show protection, since they don't have a mature immune system
- a second dose is necessary to 'rev up' the immune system

For a study in modern propaganda techniques, the reader is directed to the entire *AP* article:
https://web.archive.org/web/20090925013406/http://news.yahoo.com/s/ap/20090921/ap_on_he_me/us_med_swine_flu

The article is nothing more but a dressed up, watered down version of the NIH's own article [4] which came out the same day - "**Early Results: in Children, 2009 H1N1 Influenza Vaccine**"
https://web.archive.org/web/20090923181003/www.nih.gov/news/health/sep2009/niaid-21.htm

Associated Press offers not one bit of independent research, commentary, criticism, or analysis. Except for deliberately omitting some of the glaring lack of science in the NIH article, all that *AP* does is to try and give a junior-high parroting of the high points from their master's voice.

The *AP* article obediently adopts the NIH's new pet word "protection" across the board:
"Protection kicks in for older children within eight to 10 days of the shot..." Only a tested and proven vaccine could even hope to provide protection. The clinical trials on swine flu vaccine are less than a month old, and won't be completed until April 2010. The only thing these shots are protecting at this point is an experiment on the live population.

Trying to make believe that giving a 6 month old infant 4 flu shots would be 'normal' Fauci: "...*the very young often need 2 doses of vaccine against regular winter flu*." Really? Why has he never shared that secret with anyone before now? CDC has never recommended 2 flu shots for children.

Flu shots were added to the vaccine Schedule back in 2005, beginning at 6 months of age, and yearly thereafter. [1] One shot. What is Fauci trying to pretend? He then bumbles on... "*this is very good news for the vaccination program*." Why would we care what is or isn't good news for the vaccination program? At $1 billion per shot approved, I guess it would be good news for the vaccination program. What does that have to do with the health of our kids? Another graduate of the Josef Goebbels school of social graces: always be upbeat...

CDC's Schuchat, another towering medical genius, obviously off her meds, then pipes in "*it will be OK for kids to get one shot in each arm on the same visit*." Excuse me, Dr Mengele? Did you remember in first quarter med school when you learned that both arms were attached to the same body, sharing the same systemic circulation? Exactly what clinical trials confirm this personal hallucination of yours? And this is the principal representative of our CDC?

The *AP* article plods bravely on: *...The new swine flu seems no more deadly than regular winter flu, which every year kills 36,000 Americans and hospitalizes 200,000. But there's an important difference: This H1N1 strain sickens younger people more frequently...* [3]

There are no references for these sweeping statements in the *AP* article - again, it is attempting to be summarizing NIH's article. What new swine flu are they talking about? What disease? See the original Swine Flu chapter [1] at www.thedoctorwithin.com for that discussion.

Flu Deaths Stats

Next item, the figure of 36,000 deaths from flu is an old CDC sales technique that has been employed unchanged for the past 20 years. Actual figures, according to CDC's own documents [5] put the true figure at closer to 500 per year: www.cdc.gov/nchs/datawh/statab/unpubd/mortabs/gmwki10.htm

As we thoroughly explore in the full day vaccine seminar, there is no way that 36,000 people die from flu every year in this country, not by any stretch, although this figure is rampantly misquoted in every media. The sales job here is that the new chimera we call swine flu will be no greater threat than regular flu has been all these years, so it will be easy for the vaccine to control it, the same way as flu is controlled by flu shots. That's the perception they're going for here. But even if their own figures were accurate, they admit that there has been no change in annual flu deaths in the past 20 years, even though we started mandating flu shots in 2005. So what good have vaccines done? This is supposed to be an endorsement for the new swine flu shots?

NIH: preliminary sleight of hand

Let's continue with the *AP* article: "*To determine the right child dose, the NIH set up studies involving 600 children, from babies to teenagers*." [3]

https://www.seattletimes.com/seattle-news/health/govt-1-swine-flu-shot-enough-for-older-kids/

That is actually true. At present there are 5 separate swine flu vaccine trials being done on sample sizes of about 600 children. [2] But *AP*'s next statement is a deliberate misrepresentation: "*About 76 percent of 10- to 17-year-olds showed strong protection after one H1N1 shot*."

Looking at the actual studies themselves [2] we learn that they won't be finished until April 2010! So what is Fauci talking about here? Answer: *preliminary findings* based on a select group of *25 children* ! But you can't find that fact out in the irresponsible *AP* whitewash promo. No, for that fact you have to go to the NIH site, and actually read the article that *AP* is supposed to be reporting on:

Early Results: In Children, 2009 H1N1 Influenza Vaccine Works Like Seasonal Flu Vaccine – 21 Sep 09. [4]

Easy to see misrepresentation right here -- the *AP* article leads us to believe these high numbers were conclusive final evidence from complete studies. 76% favorable response would be a gratifying

long term result in any major study, but we find out that is only after 10 days, looking at only 25 children within the entire sample of 600 subjects. [4]

https://web.archive.org/web/20090923181003/www.nih.gov/news/health/sep2009/niaid-21.htm

Again, don't miss the point: these high numbers of "protection" are *preliminary findings only*. The formal studies, which are the only ones being done in the whole world to test the safety and efficacy of the new swine flu vaccines, these studies have just begun last month, August 2009. Preliminary findings are meaningless in formal science. That's why they design the entire study, and await the final outcome before making conclusions.

Here we see one of the most disconcerting and insidious characteristics of the new swine flu sales program: enlisting mainstream media to deliberately portray preliminary findings as definitive, conclusive scientific results. This only happens in the world of marketing. Real scientists are embarrassed by it.

The NIH report is further compromised in its own second paragraph wherein it quotes Fauci prematurely ejaculating these minor preliminary findings into an overblown sales pitch for a completely untested experimental vaccine, immediately making policy statements based on this tiny amount of skewed information:

It seems likely that the H1N1 flu vaccine will require just one 15-microgram dose for children 10 to 17 years of age.

Oh, does it really seem likely, Tony? Does it indeed? Well we're certainly grateful to have someone like you at the helm, someone whose instincts and feelings we can trust without actually carrying out the complete clinical trials themselves.

Infants are Not Miniature Adults

One final important revelation about the *AP* article, and perhaps the agenda of the Director of the NIH: "*Younger children simply don't have as mature an immune system*," Fauci explained. "So a first dose of vaccine against a flu strain they've never experienced acts as an introduction for their immune system, and a *booster shortly thereafter revs up that immune response*." [4]

Wow. Let's take a breath here, or maybe a cocktail. For the first time in history we have the director of the National Institutes of Health enunciating in a public worldwide forum one of the principal reasons why young children should not be vaccinated at all: they don't have a mature immune system. Absolutely true. No child is born with an intact immune system. That very complex biological symphony of interrelated allergic responses, antibodies, antigens, self-recognition, cell response, etc – about which we still have only the most fragmented and vaguest knowledge – struggles its way into existence during the early years of the child's life. It needs no help, no interference, no enormous experimental toxic load, especially one so politically contrived, in its fight to survive.

True to his training, Fauci immediately sidetracks us from that fact of nature to a landmark illusion of American pseudo-science: pretending that a flu shot in a 6 month old is a gentle natural gradual normal immune-building stimulus that will coax the infant immune system into being: "...an introduction to their immune system..." Each flu shot contains 30x the adult safe level of mercury, according to FDA's own toxicity index.

Fauci then absurdly follows that falsehood with a sublimely idiotic non-sequitur: the subsequent booster shot 'revs up the immune system'. Revs up the immune system. Jesus wept.

This is not the president of Harley Davidson talking here, my friends. This is the director of the branch of government that is in charge of providing funding for all the medical research done in this country, controlling an industry that is in excess of $1.2 trillion annually. And this is his perception of the normal development of an infant's immune system: an engine that needs to be 'revved up'. This is the individual who controls policies and input and decisions on what substances will be mandated into your child's bloodstream.

Revs up the immune system.

Swine Flu Vaccine Clinical Trials

There are actually five similar clinical trials on the new swine flu vaccine, being carried out in various locations, all having just begun, all scheduled to be complete in about 6 months: spring of 2010. [2] And yet the *AP* article has just informed us that the swine flu vaccine will be available in less than one month - October 2009! Untested.

Going now to the recent published report (15 Sep 09) of one of the five swine flu vaccine clinical trials, the one by Sanofi Pasteur (http://clinicaltrials.gov/show/NCT00944073) [6] we learn that their trial began in August 2009 and will go until April 2010. The sample size is 650 children.

These children are all receiving doses of an H1N1 vaccine, although whether it's all the same strain is never addressed. They just refer to it as the 2009 H1N1 virus, whatever that may be. As we learned in the Swine Flu chapter at www.thedoctorwithin.com there are dozens of strains of H1N1 virus, none of which has ever been proven to be the cause of any disease in humans. Including swine flu. So even though this fact is uncontested, what is certain is that the swine flu vaccines will all contain derivatives of some H1N1 virus. And that's what all of America will be getting.

Imaginary Disease

Now let's ruminate on that fact for one second here and not gloss over it. Swine flu as a disease has never been proven to exist. Caught up in the media-driven hysteria of global pandemic, thousands of cases of something in several countries have been counted as swine flu for the past 5 months without any conclusive testing that verifies all these people have the same disease. Three months ago the specter of H1N1 was raised, with no verifiable proof it was a virus that all the cases had in common. But if we have to make a vaccine, we need a pathogen, and this was the best theory they could come up with: H1N1.

After another month, with no conclusive testing of the dozens of strains of H1N1 that exist, the claim was suddenly made that swine flu was being caused by a "novel" H1N1 virus, suggesting they found a brand new strain of disease-causing flu virus... No proof of testing on how they supposedly discovered that one novel strain was ever offered or brought forth, or even asked for, from any scientific quarter. At the same time the CDC continued to maintain on their website that a positive test for swine flu was merely the presence of any Influenza A virus, of which there are hundreds of strains.

Again, there is no solid proof whatsoever that all these thousands of cases being counted in all the various countries during the past 5 months – there is no evidence that it wasn't just plain old flu. All of it.

It was almost as though we are watching the birth of a religion here – unsubstantiated claims, vacillating science, relentless hype from irresponsible media trying to stay ahead of the curve, government bureaucrat officials falling all over themselves to magnify the potential of the global threat, lest anyone accuse them of down-playing the possible horrors of the coming pandemic, followed by **hundreds of millions** in contracts being awarded to several vaccine manufacturers to create 251 million doses.

Washington Surprise: Unrestricted Mercury in New Vax

A few days after the *Associated Press* article, another shocking bit of information came: the new swine flu vaccines will contain high levels of mercury! Washington state Health Secretary Salecky announced [2] that the state of Washington just lifted allowable limits of thimerosal in the new swine flu vaccines, with no new levels set.

https://web.archive.org/web/20090928091425/http://www.doh.wa.gov/cfh/immunize/providers/h1n1-thimerosal.htm

The announcement was masterfully phrased, obviously the work of professional Bernays-type publicists:

"*Lifting mercury limits for H1N1 vaccin*e will give pregnant women and parents or guardians of children under three the option of getting the vaccine if they want it."

Couching the issue in terms of availability to poor pregnant women sidesteps the obvious: it would also give these women the option of exposing themselves and their unborn children to unrestricted levels of the third most lethal neurotoxin known to man: organic mercury. Perhaps realities like that don't make for good promo copy.

All this for a disease that has never been proven to exist, and has been admitted by the CDC to be generally mild and self-limiting.

The Washington state declaration was helpful in that it quoted from one of the 5 swine flu vax manufacturers – Sanofi Pasteur – from their 15 Sep 09 announcement [6] that their new swine flu vaccination had just been licensed by the FDA. Even though the wording is confusing, reading Sanofi's entire statement does give one the impression that their brand new swine flu vaccine, which was in clinical trials for only 5 weeks, has actually been approved by the FDA for general use.

This is in line with CDC's well published expectation to have the vaccines available by October 2009.

Sanofi states that the clinical trial just began on August 6. Now remember – none of the clinical trials is scheduled to be completed until April 2010. Which begs the questions:

- Why are vaccines being licensed at the very beginning of the clinical trials?
- If they're brand new vaccines, why do they have thimerosal at all, let alone unrestricted levels?

Something's not right here.

Perhaps we can gain some insight from the tone of Sanofi's honcho:

"*Obtaining FDA licensure of this vaccine for A (H1N1)* pandemic response is a key milestone that will enable Sanofi Pasteur to provide a licensed vaccine to the U.S. government to support pandemic immunization efforts," said Wayne Pisano, President and Chief Executive Officer of Sanofi Pasteur.

Sanofi is now referring to their vaccine as the *Influenza A (H1N1) 2009 Monovalent Vaccine.* This is the latest incarnation, or at least the newest name for the swine flu vaccines. No more 'novel,' no more just plain H1N1 vaccine – by putting H1N1 in parentheses after Influenza A, Sanofi is trying to create the illusion that H1N1 is the same thing as Influenza A virus.

We explained this completely in the swine flu chapter [7] - hundreds of strains of Influenza A, and dozens of strains of H1N1. The pretense here is that by meticulous testing they have identified the exact strain that has caused all these deaths and cases of swine flu in all these countries during the past 5 months.

Nothing could be further from the truth.

The spectre of thimerosal having been raised portends the possibility, indeed the likelihood, that the vaccine manufacturers who have just been awarded these huge contracts to rush a vaccine onto the market – that the new vaccines will not be new at all, but rather old stockpiled vaccines that have been sitting around for years: either old flu vaccines or Avian flu vaccines, or whatever. Virtually anything with a fragment of any flu virus might qualify.

Again, if the vaccines are going to be brand new, created right now at this time, why would they have to contain thimerosal at all? If these are brand new batches, why not just leave it out? There are thimerosal-free vaccines, and have been for years. Even Salecky notes this in her statement. So why add this neurotoxin to a vaccine that we're going to be giving 2 shots of to a 6 month old infant, especially now when the connection with autism has been so clearly documented?

For years, the 'regular' flu shots contained 25 mcg of mercury, which is 30 times the adult safe level. That was bad enough that we have been doing it since 2006. And now we have just learned that there will be even higher levels of thimerosal in the new vaccines....?

The practice of trotting out old vaccines, giving them a new promo package, and re-marketing them is not new. We did the same exact thing back in 2002 with the smallpox vaccine hoax. [8] At that time a vaccine manufacturer dug up 90 million doses of old smallpox vaccines that had been sitting around in storage since 1971. With no new clinical trials, the old vaccines were 'tested' by Aventis, the company who had just received four hundred million dollars to produce a smallpox vaccine overnight, and found to be "still good."

Remember this: batches of vaccines do *have expiration dates, but they are never thrown away*. Vaccine manufacturers are the packrats of the drug industry in that regard. Just never know when any of these old vaccine batches might come in handy.

New or Reconditioned?

A working hypothesis at the present time is that faced with the "emergency" to get swine flu vaccines out immediately in order to stem the tide of the so-called global pandemic, manufacturers will be digging through their cupboards to see if they have any old stuff they can sell now just by changing the name and a little tweaking.

Historically it generally takes a year or more to create, test, and approve a brand new vaccine. If this one's being forced into existence after one month by sheer political expediency, the manufacturers are likely going to try every trick in the book. Remember, Sanofi is the same company who got the hundred million dollar contract to produce avian flu vaccine back in 2005, which they never delivered on. [9] So why on earth would they not try to sell any expired inventory as swine flu stock? Time is money.

Another company, Baxter, was recently caught by the Czech government for doing exactly that: selling unlicensed avian flu vaccine as swine flu vaccine. That was a major worldwide scandal, in all the news in September 2009. [10]

When the Czech government pre-tested the vaccine on ferrets before giving it to humans, all the ferrets died! That was earlier this month. Again, why wouldn't Sanofi or any of the others try the exact same ruse?

Not surprising that about 25% of Sanofi's recent statement on swine flu [6] is directed to their investors as a disclaimer about the way they are marketing the vaccine. The economics of politics, exemplified in both the swine flu disaster of 1976 and also the smallpox vaccine scam of 2001.

In both instances the excuse was offered by the FDA that there was no time to test the vaccine because of the 'imminent danger' of the 'pandemic.' And so the vaccines were rushed through the approval process without completing the clinical trials. All politics, no science. In 1976, hundreds of people died from that mistake. In 2001, they took the easy way out - after the $3 billion was spent they scrapped the whole smallpox vaccine program.

Remember?

It's eerie. This identical urgency over today's swine flu program is being stoked almost daily by inflammatory, largely unfounded news stories, all directed toward the same outcome: there simply isn't time to test these new vaccines. So let's just get them out there to the children and pregnant women such as they are. We'll sort of the details later.

Like toxicity, lethal side effects, permanent neurological damage, autism, etc.

Mandatory Vaccines?

Almost as bad as the promotion of an untested vaccine for a nonexistent disease is all this internet noise making hysterical claims about subtextual Machiavellian aspects of the swine flu program. Like the stories predicting mandatory swine flu vaccination which evoke Third Reich policies of quarantining any objectors in stadiums or mass detention centers (which actually is law in this country at present, part of the Homeland Security Act), etc. ...

In reality all this is completely unnecessary. There's no need to make swine flu vaccine mandatory. No vaccine in history has been supported and promoted by such an enormous, well-crafted, incessant global media blitz. And of course it's working: most people can't wait to get the new vaccine.

In the midst of everything we do not know, one fact is certain: without hyperbole or sensationalism, the new swine flu vaccine coming next month - unidentified, untested and untried - will be the most dangerous immunological experiment on this country's children in the past 30 years.

LOCAL 12

Hospital Workers to get Mandatory Flu Shots

Local-12, 1 October 2009, 6:55 am
https://web.archive.org/web/20091105074915/http://www.local12.com/news/local/story/Hospital-Workers-To-Get-Mandatory-Flu-Shots/NAKhVWrVb0i0il7yi9aJUA.cspx

Workers at Christ Hospital in Mount Auburn will be required to get the seasonal flu shot this year... or be forced to stop working at the hospital.

The hospital says it made the change in policy, from voluntary shots to mandatory vaccinations, for the safety of workers and patients. They say in just the last month, they've seen a spike in the number of patients with flu-like symptoms.

All workers including residents, volunteers, medical students and vendors will need to get a flu shot. Workers with religious or medical reasons are exempt. But workers who refuse for any other reason will not be allowed to work inside the hospital. Most workers who spoke with Local 12 say they haven't heard many objections from fellow employees about receiving the shots.

The next step is vaccinations for the H1N1 virus. Doses are expected to arrive later this month and they'll be mandatory for workers in the emergency room and obstetrics.

Also, the Greater Cincinnati Health council has issued new rules for hospital visitors. No one under the age of 14 will be allowed to visit patients inside local hospital. Facilities are also restricting people with respiratory symptoms like a cough or fever.

You can learn more about the seasonal and H1N1 flu by visiting our special Flu Tracker website.

Vical shares soar on Navy's H1N1 contract

Fierce Pharma, 1 October 2009, 9:40am
https://www.fiercepharma.com/vaccines/vical-shares-soar-on-navy-s-h1n1-contract

Anyone doubting just how hot H1N1 news is right now should check out Vical's stock price this morning. The developer announced a modest $1.3 million contract with the Navy to fund the manufacturing and testing of its swine flu vaccine and the company's stock shot up 22 percent. And this was all laid out in releases weeks ago.

Vical's Vaxfectin-formulated DNA vaccine is one of the most closely watched vaccines among a new generation of treatments now in the clinic. Last spring the company inked an R&D pact with the U.S. Naval Medical Research Center to advance the vaccine. And last month the company announced plans to start human trials just weeks after the Navy funding lands. Researchers say that the DNA vaccine has demonstrated a robust response in animals.

"The current threat from H1N1 influenza and the potential for other future pandemics from strains like H5N1 call for a proactive approach to developing new vaccine technologies, such as DNA vaccines, that can be deployed rapidly," said Vijay B. Samant, Vical's CEO. "We are pleased with the Navy's vision in funding this important vaccine development program, which can benefit from their experience and capability to advance this program to the next stage."

Of course, Vical isn't the only vaccine developer to find itself in the spotlight. A slate of vaccine companies boasting new technology are also enjoying a rapid run-up in share price.

More hospitals require flu shots;
Winona Health does not

Winona Daily News, 2 October 2009, 12:05 am
https://web.archive.org/web/20091005034017/http://www.winonadailynews.com/news/local/article_9938fe26-af06-11de-9386-001cc4c002e0.html

Hospitals around the country are requiring their employees get seasonal flu vaccines to increase the number of health care workers protected against the bug.

Winona Health makes the vaccine available to its employees, who are "highly encouraged" to get the shot, said Sara Gabrick, vice president of patient care, but it does not require them.

The health care provider also plans to encourage but not require its workers to get the swine flu vaccine, expected to become available later this month.

State health officials said Thursday that Minnesota will soon receive is first batch of swine flu vaccinations - 28,000 doses in the form of a nasal spray - and health care workers will be offered the vaccines first.

While Winona Health encourages its workers to become vaccinated, other hospitals require it.

The Marshfield Clinic in Marshfield, Wis., the University of Iowa Hospital in Iowa City, Iowa, and the Nashville-based HCA hospital chain require employees receive the seasonal flu vaccine.

For the first time, workers at UW Hospital and St. Mary's Hospital in Madison, Wis., must get seasonal flu shots this year or sign waivers saying they understand the risks of not doing so.

Seasonal flu kills about 36,000 people and puts 200,000 in the hospital each year, according to the national Centers for Disease Control and Prevention.

Swine flu could kill 30,000 to 90,000 people and lead to 1.8 million hospital admissions this year, a White House report said in August.

A Winona Health spokeswoman couldn't immediately say how many of its employees typically receive the seasonal flu vaccine.

Louisa Hodge

Get a Flu Shot at Sacramento International

News 10, ABC, 2 October 2009
https://web.archive.org/web/20091008060505/http://www.news10.net/news/story.aspx?storyid=67986&catid=2

Sacramento, CA – Starting Friday morning, flu shots are available at Sacramento International Airport. An airport spokesperson says it's a service aimed at the the busy traveler and it's another way for the airport to try to stay flu-free.

The airport will provide flu, pneumonia, and tetanus shots in Terminal A. The vaccinations will be available in Terminal B on Wednesday, October 7. The flu and pneumonia shots cost $30 and the tetanus shots cost $35.

Passengers can get a shot either before they board a flight or after they land. Some travelers think it's a good idea.

"There's no reason that I wouldn't do it," said traveler Steve Chalkins. "I think it's a good service for people."

"I think it's a wonderful idea because you have people coming in from all over the country with different germs and it would protect some of us," said traveler Maxine Fields.

But some people are a little concerned about this non-traditional location for inoculations.

"If you were getting one here and you have any kind of reaction within the first hours or something, you might be on the plane and it might be kind of difficult to do anything about it," said one traveler.

The most common side effects of the flu shot are soreness of the arm, cold symptoms, and in some cases, a low-grade fever. The CDC reports serious reactions are very rare.

NBC NEWS

What you need to know about swine flu shots
Inoculations against swine flu are expected to gear up in mid-October
Here's what you need to know

NBC News, 5 October 2009, 9:37 PM +08
https://www.nbcnews.com/id/wbna33175413

And we're off: Swine flu vaccinations begin this week, after months of preparations and promises. But don't start bugging your doctor about an appointment just yet.

Inoculations won't gear up in earnest until mid-October, when at least 40 million doses against what scientists call the 2009 H1N1 flu will have rolled out, with more arriving each week after that.

Here's what you need to know:

Q: Why not wait to start until there's enough for everybody instead of the confusing here-and-there vaccinations?

A: Even though Sunday was the official start of flu season, this H1N1 wasn't heeding the calendar – it's already causing illness in nearly every state. That means getting vaccine to the people at highest risk is a race. So each week, states will distribute however much they have on hand.

Q: If factories are still racing vaccine out the door, how can I be sure it's safe?

A: The Food and Drug Administration clears batches of vaccine before they're released. The H1N1 vaccine is made in the same way as the regular winter flu vaccine that is used with very few, minor side effects by nearly 100 million Americans a year. There's no biological reason the H1N1 vaccine should react any differently, and no red flags have appeared in studies of several thousand people.

"What I want people to know is that no corners have been cut at all," said Dr. Anne Schuchat of the Centers for Disease Control and Prevention.

Q: Why is the nasal-spray vaccine arriving before the shots, and can I use either one?

A: They're considered equally effective, but the maker of the squirt-in-the-nose FluMist was able to finish brewing sooner. There is an important difference, though. Flu shots, made of killed flu virus, are for anyone without an egg allergy. FluMist, besides the egg issue, is only for use in healthy people ages 2 to 49. It's made of live but weakened flu virus. So some people on the first-in-line list for H1N1 vaccine aren't eligible for FluMist.

Q: Who's first in line?

A: Pregnant women; the young, ages 6 months through 24 years; people younger than 64 who have conditions such as asthma or diabetes that increase the risk of complications from flu; health workers and caregivers of newborns.

Q: I thought flu was most dangerous to people 65 and older.

A: Regular winter flu is most dangerous to older adults, but the new H1N1 is predominantly striking the young.

Q: How many shots, or squirts, will I need?

A: Most people will need one dose each of the H1N1 vaccine and the regular winter flu vaccine. But health authorities believe children under 10 will need two doses of the H1N1 vaccine, about three weeks apart. And some very young children getting their first regular flu vaccination will need two doses of it, too, for a total a four inoculations.

Q: Can I get both types of vaccine at the same visit?

A: If you're lucky enough to find a provider who has both at the same time, a jab in each arm is OK, or a jab of one and a squirt of the other. If you opt for the FluMist version of each vaccine, however, you're supposed to wait three to four weeks between squirts.

Q: What if I'm not on the high-risk list and want H1N1 vaccine anyway?

A: Only some will be physically reserved, doses sent to schools or obstetricians, for example. But eventually enough is expected for everyone who wants it within just a few weeks. The government doesn't expect people to be turned away unless that day's supplies run out.

Q: What will it cost?

A: The H1N1 vaccine itself is free because the government bought it with your tax dollars. But providers can charge a small fee for administering it, usually about $20. Regular flu shots tend to cost up to $35.

Q: If H1N1 is the only kind of flu making people sick now, why do I need the regular shot?

A: Health authorities expect regular flu strains to start circulating, too, as it gets colder; seasonal flu typically peaks in January.

REUTERS

Swine flu vaccination effort starts Monday: CDC

Reuters, 5 October 2009, 11:04 AM GMT+8
https://www.reuters.com/article/us-flu-vaccines-usa-idUKTRE5940BH20091005/

Washington (Reuters) - Healthcare workers in Indiana and Tennessee will be among the first to get swine flu vaccines in the United States on Monday, the U.S. Centers for Disease Control and Prevention said.

Vaccination clinics are scheduled for Monday morning for staff at Le Bonheur Children's Medical Center in Memphis, Tennessee and Wishard Health Services in Indianapolis, the CDC said.

Last week, the center said the first doses of H1N1 swine flu vaccine would arrive on Tuesday. The first vaccines to administered will be AstraZeneca unit MedImmune's nasal spray.

The U.S. government has ordered about 250 million doses from five companies - Sanofi-Aventis SA, CSL Ltd MedImmune, Novartis AG and GlaxoSmithKline. MedImmune had especially good production of the H1N1 vaccine and has been the first to make doses available.

The vaccines will trickle in at a rate of about 20 million doses a week, and officials are unsure how many Americans will actually get them. The U.S. government is providing them for free, but clinics and retailers may charge to administer them.

The picture is further complicated by seasonal flu vaccination, which started last month.

Pandemic H1N1 has been circulating since it was first identified in two U.S. children last March but it has picked up speed since schools returned from their summer break in August.

The CDC said it is not especially deadly, but it is affecting younger people than seasonal flu usually does and at a time of year when there is generally little or no influenza.

Dozens of children and at least 28 pregnant women in the United States have died from the virus and at least 100 pregnant women were sick enough with it to be hospitalized, the CDC said.

Pregnant women, healthcare workers and people with special health conditions including heart disease and diabetes are supposed to be the first to get the vaccine.

The New York Times

Donald G. McNeil Jr.

Swine Flu Vaccinations Start as Officials Attack Myths

The New York Times, 6 October 2009
https://www.nytimes.com/2009/10/07/us/07flu.html

As children received swine flu vaccine for the first time on Tuesday, federal health officials attacked popular myths about the pandemic and the vaccine designed to stop it.

Dr. Thomas R. Frieden, director of the Centers for Disease Control and Prevention, said in an afternoon news conference that the most common misperceptions are that this flu should ever be called a "mild disease," that the vaccine is untested and that it has arrived too late.

Flu is widespread across the country and some hospitals are getting so many emergency room visits that they have set up triage tents, but Dr. Frieden said one problem that planners had feared has yet to emerge: no intensive care units have had more patients than ventilators – something that did happen in one Canadian province last spring.

Children in several states, including New York, received nasal spray vaccines Tuesday – shots are due to begin next week – and all 50 states have started sending vaccine orders. Of the 2.4 million doses expected to ship this week, 2.2 million have been spoken for, Dr. Frieden said. Orders are expected to increase rapidly as states rent more refrigerated storage space and schedule vaccination drives.

Myths and worries about the vaccine have spread on talk radio and anti-vaccine Web sites, but Dr. Frieden seemed to debunk them on Tuesday.

While most people recover, he said, "on average, flu is not a 'mild' illness – it can make you pretty sick, knock you out for a day or two or three." And in rare cases, he emphasized, it kills.

He rejected suggestions that the new vaccine is untested. Its seed strain was created, grown and purified in the same slow way as seasonal flu shots, which hundreds of millions of people have had, and rapid clinical trials last month showed the same lack of serious side effects.

He conceded that the flu returned in force faster than a vaccine could be ready, but argued that it is not too late. Even in places like New York City that were epicenters of the spring outbreak, epidemiologists believe that only 5 percent to 10 percent of the population was infected.

"That leaves 90 to 95 percent of the population still susceptible," he said. "It's too soon to say it's too late. We don't know what the rest of the season will bring."

China began its swine flu vaccinations on Sept. 21, the first country to do so. Of the first 39,000 Chinese to get shots, only four had side effects, muscle cramps and headaches, a World Health Organization spokesman said Tuesday, wire services reported.

An 18-year-old Tibetan woman became the first swine flu death on the mainland under Beijing's control, China's health ministry announced Tuesday; there have been 28 swine flu deaths in Hong Kong, which did not use the rigid quarantines the mainland did.

New York City held an orchestrated kickoff to its swine flu vaccinations Tuesday at Children's Hospital at Montefiore in the Bronx.

Brandon Marty, 13, seemed nervous as he went first, taking a squirt in each nostril as city officials applauded. "It felt good and cold," Brandon said afterward.

His sister, Ashley, 9, was next, followed by Dr. Philip O. Ozuah, chairman of pediatrics at the hospital. They were chosen because they represented two high-risk groups set to get vaccine first: children and medical workers.

Actually, officials said, a few doses were given on Monday without any fanfare from the first batch of 68,000.

Dr. Thomas A. Farley, the city's new health commissioner, said he expected a vaccine shortage until the end of the month, when a batch of 1.2 million is scheduled to arrive.

Public school officials hope to begin giving vaccines in elementary schools at the end of the month and will send consent forms to parents. Middle and high school students will be offered shots on weekends.

CP 24

Helen Branswell

As U.S. starts swine flu vaccination, vaccine proponents watch with concern

CP 24, The Canadian Press. 6 October 2009, 7:28 AM EDT
https://www.cp24.com/mobile/as-u-s-starts-swine-flu-vaccination-vaccine-proponents-watch-with-concern-1.441110?cache=yesclipId10406200text/html;charset=utf-80404/7.578962/7.246408/7.129018

Toronto - The United States began to vaccinate its citizens against swine flu on Monday, one of the first countries to roll out its portion of what may be an unprecedented effort to immunize upwards of a billion people around the world over the next few months.

Health-care workers in a Memphis, Tenn., hospital were among the first in the U.S. to receive the vaccine, which is currently only available in the U.S. in nasal spray form. Injectable vaccine is expected to start flowing out of the production pipeline soon.

With substantial H1N1 activity in the U.S. at present, officials are relieved vaccine is starting to become available five months after the new virus was first detected.

The relief is tempered, however, with the knowledge that the coming weeks will be challenging at best, given the difficulties of getting still limited amounts of vaccine to the people who want it. If things go badly, they know, the reputations of flu shots specifically and vaccines in general could take a beating.

"I think it will be tough," predicted Dr. Paul Offit, chief of infectious diseases at Children's Hospital of Philadelphia and a key figure in the pro-vaccination movement.

Dr. Anne Schuchat, director of the national centre for immunization and respiratory diseases at the U.S. Centers for Disease Control, agreed.

"I think that the positive impact of a successful program could be huge. And the unintended consequences of problems in the program would also be huge," Schuchat admitted.

"So I think that public health and the health-care system do feel a lot of pressure in trying to make this go as smoothly as possible. And then on top of that we do have this race against the virus, which is continuing to cause disease around the world."

The U.S. is not the first to begin to vaccinate; China began a few weeks ago. And Australia started to offer pandemic flu shots last week.

Canada is currently only scheduled to begin vaccinating in early to mid November, though Chief Public Health Officer Dr. David Butler-Jones has said he could ask Health Canada to release the vaccine a few weeks earlier under special licensing provisions if the risk from the virus seemed to increase.

Eventually, the World Health Organization has predicted, three billion doses of the new H1N1 vaccine could be produced over 12 months. It remains unclear whether global delivery systems are in place to administer so many doses. It's also unclear whether there is that much demand for vaccine against this relatively mild pandemic strain.

In the U.S. and Canada, poll after poll shows somewhere around half the population – sometimes less – plans to get a flu shot. While that's better than the uptake rate for seasonal flu vaccine – last

year just under 30 per cent of Canadians over age 12 got a flu shot – it is not as high as officials would like to see.

Dr. Michael Osterholm, an infectious diseases expert at the University of Minnesota, said the population at this point breaks down into three groups: Those who are eager to get the vaccine and who will be annoyed by any delay; those who are undecided about whether to get it and who plan to watch how the roll out unfolds before making up their minds; and those who either reject vaccines in general or flu vaccines specifically.

Any signs of adverse reactions that might be linked to the vaccine will drive away the second group, said Osterholm, who is director of the university's Center for Infectious Diseases Research and Policy.

And Offit said the third group will jump at the opportunity to discredit the vaccine if and when such events arise. He admitted that prospect has the pro-vaccine forces essentially holding their collective breath.

"Of course," Offit said. "Because I think when the anti-vaccine groups get a hold of something, they're very good at it."

"They're very good at public relations. They understand how to get the ear of the media and how to get the ear of Congress."

Schuchat and colleagues at the CDC have been trying to inoculate the program against the impact of that kind of event, warning that even though these vaccines should be as safe as seasonal flu shots, things will happen once mass vaccination starts. Pregnant women will miscarry. People will have heart attacks. Rare neurological disorders may occur.

But these things happen all the time among people who haven't just received a flu shot. Determining whether the events were caused in some way by the vaccine or – as experts think is more likely – are ere coincidences will be critical. Unfortunately, the work needed to answer those questions takes time.

"If we detect a signal we'll need to investigate it carefully and even with rapid investigation, it may take some time," Schuchat said.

"I think that patience is a hard thing to have when there's disease around us or vaccination needs to occur quickly. So I think expectations about how quickly we'll be able to understand signals – that's a tricky issue."

Osterholm said the situation is made more difficult still by the fact that there will be glitches in distribution and the fact that no one knows what is going to happen with the virus.

If there appears to be an increase in reports of deaths among children and pregnant women, demand will rise, he predicted. But if severe cases remain rare and the illness is perceived as mild, people could decide to take a pass.

"We're not quite in Never Never Land, but we are charting previously uncharted waters, because of all these issues," Osterholm said.

Swine Flu Vaccine Reaches an Anxious Nation.

The New York Times, 6 October 2009
http://www.nytimes.com/2009/10/06/nyregion/06vaccine.html

The fear of swine flu is being compounded by new worries, this time among primary care doctors who say that they are swamped by calls from patients seeking the new vaccine, and that they are ill-prepared to cope with the nationwide drive to immunize everyone, particularly children and chronically ill adults.

The federal Centers for Disease Control and Prevention released the first doses of vaccine on Monday. But many doctors, especially pediatricians, say they know little about the program and have been deluged with questions.

At the same time, the pediatricians are struggling to figure out how to administer perhaps thousands of doses quickly in small offices with limited staff, while still dealing with other illnesses.

Some said they were considering hiring nurses just for the vaccinations and setting aside days when children would be vaccinated in alphabetical order.

At Westchester Pediatrics, an office with 6,000 to 8,000 families in Hartsdale, N.Y., exasperated doctors have added a new choice to the office answering machine: "If you have a question about the flu vaccine, please dial 6." Pressing 6 produces a further message saying that the swine flu vaccine is not yet available, and to keep checking the CDC.gov Web site for updates.
For those who are not satisfied, a sign in the office waiting room counsels patience.

Kathryn Paterno, the office manager, summed up the situation as "a nightmare." – "People want it," Ms. Paterno said of the swine flu vaccine. "When they listen to news reports, they pick out bits and pieces – 'swine flu, get it' – but they don't quite comprehend that we don't have it yet, and we're dealing with a quite affluent socioeconomic group here."

When asked whether his office had received vaccine inquiries, Dr. Herbert Lazarus, a pediatrician on the Upper West Side, said only half-jokingly: "Do you think that's accounting for two-thirds of our phone calls, or three-quarters?"

In Philadelphia, Dr. Shea Cronley of Advocare Society Hill Pediatrics said she was concerned that emergency rooms were starting to see a rise in flu cases, but she did not know when she would be getting her share of vaccine. – "We're waiting," she said.

The Centers for Disease Control has embarked on an extensive immunization drive with a goal of producing 195 million to 250 million doses of vaccine.
The vaccine is being distributed free to local jurisdictions, like city and state health departments, which are responsible for taking orders from doctors, hospitals, school systems and the like. Normally, doctors order vaccines directly from manufacturers.

As of Monday, 62 states or localities had put in orders for a total of more than 1.7 million doses.

Actual delivery will lag, however, adding to the confusion about when doctors will get their share. The New York City Department of Health and Mental Hygiene said Friday that it expected to get only 68,800 doses by early this week, and New York State expected 59,000. Increasing amounts of vaccine are expected to be available in the next few weeks.

Even the city's public hospitals remained uncertain about the logistics. "We are prepared to provide access to the H1N1 vaccine," said Ana Marengo, a spokeswoman for the New York City Health and Hospitals Corporation, "and the piece of information still missing is knowing when it will be available and how much everyone will get."

Kathleen Sebelius, secretary of Health and Human Services, acknowledged the concerns, but said it was up to local health departments to run interference between doctors, hospitals and the federal government. – "I've heard a lot about how much confusion there is about how to get the vaccine," Ms. Sebelius said Friday. – "We'll never, from the mother ship, give one national picture," she added. "It's going to be many, many local decisions. What we do need to know is, if that information isn't getting across, then maybe we can do something about it."

Many school districts, including New York's, are making plans to immunize children at school. But in interviews over the last few days, doctors said they were confused about whether they were expected to vaccinate their patients, or whether schools would take the lead. – "That's a critical issue, and I can't find out," said Dr. Max Van Gilder, a New York City pediatrician in an office with about 4,800 patients.

In the Chicago suburb of Evanston, Ill., Dr. Irwin Benuck, a pediatrician in a practice of 8,000 patients, said parents were flooding the office with questions about when the vaccine would be available. He has ordered the vaccine from the local health department, but he does not know when he will get it. He is telling families also to look to other sources, like schools and drugstores.
"We've heard nothing in terms of timetables," he said.

Dr. Jane R. Zucker, assistant commissioner of New York City's bureau of immunization, said the city considered doctors to be the first line of defense, and the schools a backup for children who did not have private doctors.

She said that New York would be splitting its first shipment of vaccine (in the form of a nasal mist unsuitable for pregnant women and people with chronic health conditions) between health care workers in hospitals and clinics, who are required by state law to be immunized, and doctors treating children.

She said the city expected to get the vaccine into its elementary schools by early November and was considering setting up weekend vaccination clinics for older children.

Some doctors wondered whether the vaccination drive was necessary for a flu that has caused only mild symptoms in most cases. They said some of their patients had expressed doubts about whether the vaccine had been sufficiently tested for safety, and they admitted that they were sympathetic to those fears.

Dr. Lazarus, the Upper West Side pediatrician, recalled that as a child, he had lined up for the polio vaccine on a sugar cube. But it was the early 1960s, he said, and by then the science of that vaccine was well established. "You don't always want to be the first person on line to get the vaccine – do you think?" he said.

Dr. Jessica Sessions, director of pediatrics at the Ryan Center, which treats many poor patients on the Upper West Side, said that she was reassuring patients that she herself was going to get the vaccination, to protect her twins, who are 4 ½ months old.

Dr. Van Gilder said that when he got his share of vaccine – and he was wondering when that would be – he was planning to conduct a vaccination blitz, immunizing 250 children a day in alphabetical order.

"It's a logistical nightmare," he said.

Swine flu spray demand outstripping supply

NBC News, 6 October 2009, 8:12 pm UTS
https://www.nbcnews.com/id/wbna33196660

The initial swine flu vaccine doses this week will be the nasal spray version, and arm injections will begin next week to help meet demand, health officials said Tuesday.

About 2.4 million doses of nasal spray are available so far, with about 2.2 million doses drawn down or ordered. However, the spray is not recommended for some people who are most in danger of complications from flu, including pregnant women and people with asthma. While some priority groups like health care workers and healthy children 2 or older can get vaccinated this week, pregnant women and others at risk should wait.

The vaccine first became available in some states on Monday. Because there's a limited amount of vaccine available and some people aren't eligible for it, demand so far is outstripping supply, said Dr. Tom Frieden, director of the Centers for Disease Control and Prevention, at a Tuesday press conference. He did not say by how much.

Swine flu is widespread across the country, although cases are on the upswing in some areas and seem to be receding in others, Frieden said.

According to the latest CDC data, reports are falling a bit in five regions that comprise about half the country – the New York-New Jersey area; the Southeast; the Midwest; the central Plains; and the region that includes Hawaii, California, Nevada and Arizona.

However, the unpredictable flu could make a resurgence, Frieden said, noting it's not too late for people in any region to be vaccinated.

"Even in places where flu has been widespread, it's affected 5 percent to 10 percent of the population. That means 90 percent to 95 percent of the population is still susceptible," he said.

The CDC doesn't have an exact count of swine flu deaths and hospitalizations, but existing reports suggest the infection has caused more than 600 deaths and more than 9,000 hospitalizations since the virus was first identified in April.

The government keeps a more careful count of deaths of pregnant women and children attributed to swine flu. CDC officials say they are aware of 28 deaths of pregnant women and about 60 of children.

Ordinary flu jab may protect against H1N1 – study

Reuters, 7 October 2009, 7:44 AM GMT+8
https://www.reuters.com/article/economy/ordinary-flu-jab-may-protect-against-h1n1-study-idUSN06445278/

WASHINGTON, Oct 6 (Reuters) - Mexican researchers say they have some evidence that the ordinary seasonal flu vaccine may offer some protection against the new pandemic H1N1 swine flu – contrary to other studies.

They found that people who had been vaccinated against seasonal flu were far less likely to be sick or to die from H1N1 than people who had not been immunized against seasonal flu.

"These results are to be considered cautiously and in no way indicate that seasonal vaccine should replace vaccination against pandemic influenza A/H1N1 2009," Lourdes Garcia-Garcia and colleagues at the National Institute of Public Health in Cuernavaca wrote in the British Medical Journal.

But they said the findings might offer some good news for people who have been vaccinated against seasonal flu, especially as governments are just beginning to distribute newly made swine flu vaccines.

The new H1N1 swine flu virus is a very distant cousin of the H1N1 seasonal flu virus, which is included in the mixture provided every year in the seasonal flu vaccine.

Most studies have shown the annual vaccine provides little or no protection against H1N1, likely because it is very different.

One study in Canada suggested that in fact people who got seasonal flu vaccines may be more likely to become infected with H1N1, although the World Health Organization and the U.S. Centers for Disease Control and Prevention both expressed doubts about the findings.

Garcia's team studied 60 patients with confirmed swine flu and 180 similar people with other diseases being treated in the Mexico City area.

The Mexican government distributes seasonal flu vaccine.

Only eight people who had been vaccinated against seasonal flu were among the swine flu cases, the researchers reported. They found that 29 percent of unvaccinated people in the study became infected with H1N1, versus 13 percent of vaccinated people.

None of the vaccinated people died, but 35 percent of swine flu patients who died had not been vaccinated against seasonal flu, they found.

"Seasonal vaccination might protect against the most severe forms of the disease," the researchers wrote.

Menno de Jong of the University of Amsterdam and Rogier Sanders of Cornell University in New York said the study shows some protection but said what the world really needs is a universal flu vaccine that protects people against all strains.

Currently, the seasonal vaccine must be formulated every year because influenza viruses mutate, and new strains, such as the H1N1 swine flu, require a completely new vaccine. The new H1N1 vaccine took five months to formulate and manufacture.

Flu Shots Delayed in Canada

The Wall Sreet Journal, 7 October 2009, 12:01 am ET
https://www.wsj.com/articles/SB125487330214569325
https://web.archive.org/web/20150525033239/https://www.wsj.com/articles/SB125487330214569325
https://www.massnurses.org/2009/10/07/oct-7-09-wsj-flu-shots-delayed-in-canada-unpublished-study-showed-seasonal-shots-could-increase-h1n1-risk/

TORONTO – An unpublished Canadian study that suggests getting an *annual flu shot may make it easier to contract swine flu* has caused most provincial governments in Canada to postpone or limit seasonal-flu vaccination programs.

The study remains a mystery in many ways. It is being reviewed for potential publication in a scientific journal, but the authors won't say which one. Few people have seen the data, and some experts have expressed skepticism of the results.

The study is co-authored by researchers from the British Columbia Centre for Disease Control, the Ontario Agency for Health Protection and Promotion and Laval University in Quebec.

The World Health Organization isn't recommending that seasonal-flu vaccinations be postponed. Public-health officials in the U.S., Australia and other countries said their own data doesn't show such links between seasonal-flu-shot recipients and people who have gotten the new flu strain, known as the 2009 H1N1 flu.

Thomas Frieden, director of the U.S. Centers for Disease Control and Prevention, said at a recent news conference that there was no "real explanation technically or scientifically" for an association between the two.

Local governments are taking no chances. Twelve of Canada's 13 provinces and territories are delaying the rollout of seasonal-flu shots for the bulk of their populations until after their H1N1 inoculations are complete – likely at the end of this year.

The study "*wasn't something we felt we could ignore*," said Perry Kendall, provincial health officer for British Columbia, which like most provinces is limiting seasonal-flu shots to people ages 65 and older until after it has finished its H1N1 vaccinations. "*Why would you want to run the risk of doubling peoples' risk of getting H1N1*?" said Dr. Kendall, who noted that he has seen the data and talked to the study's authors.

The study began after researchers in British Columbia this summer found a possible link between contracting H1N1 and receiving flu shots the previous season, for some people in the province.

The researchers shared the information with colleagues in the other provinces, some of whom in turn found their own links, said Dr. Kendall. Those results were collated into one study covering about 2,000 confirmed cases of H1N1 in places such as British Columbia, Ontario and Quebec. It found that people who got flu shots last year were about twice as likely to contract swine flu as those who weren't vaccinated, according to sources who have seen the study's data.

The Public Health Agency of Canada commissioned an international panel of experts to take a look at the study's methodology; that panel last week said it found no methodological errors and that the study has "merit," an agency spokeswoman said.

The WHO reviewed the Canadian study and data from other countries in a teleconference late last week with flu experts both inside and outside the agency, including the Canadian researchers involved in the work. "Based on that review, WHO is not issuing any general warning about seasonal-flu vaccine," spokeswoman Aphaluck Bhatiasevi said.

The WHO's immunization advisory group will also discuss the study at a meeting at the end of this month, Ms. Bhatiasevi said.

Canada's local governments said the study was just one factor in their decisions to put off seasonal-flu shots. Provincial health officials said they expect H1N1 to be the dominant flu strain in Canada this winter, as it was in most countries in the Southern Hemisphere during their winter; it thus makes sense to concentrate resources on H1N1 first, they said.

Concurrent inoculations for seasonal flu and H1N1 – as are being given in the U.S. and other countries – would be a logistical nightmare, and it is unclear what will happen if both vaccines are administered at the same time, said British Columbia's Dr. Kendall. "We don't know if you can give H1N1 in one arm and another in the other arm," he says. "Does one vaccine trump the other?"

U.S. public-health officials have said it is safe to get both shots at the same time.

In the U.S., seasonal-flu vaccinations began earlier than usual this year, in hopes of avoiding a crush of simultaneous demand for H1N1 and seasonal-flu vaccines.

The Guardian

Swine flu fears grow as NHS staff shun vaccine

The Guardian, 11 October 2009, 22.39 BST
http://www.guardian.co.uk/world/2009/oct/11/swine-flu-pandemic-vaccine-nhs

The Department of Health has ordered NHS bosses across England to ensure that frontline staff get immunised against swine flu amid growing signs that many doctors and nurses intend to shun the vaccine.

Chief executives and boards who run hospitals, primary care trusts and strategic health authorities have been told to urgently maximise the number of workers having the jab. Leading DH figures including Sir Liam Donaldson, the chief medical officer, have written to them six times in the last five weeks stressing the need for action before the second wave of the pandemic causes major problems.

Ian Dalton, the NHS's national director of flu resilience, last week warned that vaccination of nurses, doctors and other frontline staff was "absolutely critical" and that widespread take-up of the jabs "will help us to save lives".

The DH's letters stress that patients' health could be put at risk and the NHS left seriously short-staffed through virus-related absenteeism if senior managers do not overcome "perceived obstacles" to the vaccination of workers. Swine flu's threat is so great that the NHS must avoid only small numbers of personnel getting immunised, as usually happens with seasonal flu every winter, the letters add.

They stress that vulnerable patients could be endangered if staff decide not to heed repeated urgings from Donaldson and other senior figures to have the vaccine. There are growing signs that large numbers of workers will shun the jabs because they see them as unnecessary and potentially unsafe.

Dalton wrote to the chief executives of local NHS organisations in England on 10 September telling them: "We all know that uptake of the seasonal flu vaccine among NHS staff is traditionally low. It is an NHS board responsibility that we do not find ourselves in this position with the swine flu vaccine."

But hospital chief executives have told the Guardian that they expect as few as 10%-20% of their staff to get vaccinated and cannot fulfil the DH's demands because the jabs, which are due to begin within days, are entirely voluntary.

One chief executive of a busy urban hospital in one of the swine flu "hotspots" said: "At the moment in my hospital if nothing changes then it could be that 10%-20% of staff have the swine flu jab … Staff could have the virus and pass it on to patients, a proportion of whom will die, albeit a very small proportion."

He added: "The other consequence is that if loads of staff go off with swine flu that will leave us short-staffed, which is dangerous to patients. That's a bigger danger than transmission."

Another hospital chief executive said: "Ideally it should be 100% of frontline staff having the swine flu vaccine. But it obviously isn't going to be. I hope we'll get at least the 50% we usually get

for seasonal flu. This is important because although this strain of swine flu is mild in most people, if it's contracted by someone with an underlying health condition that can be serious."

One medical director at another hospital added: "The word on the street in NHS staff circles is that the vaccine is no good and you shouldn't bother with it. Nurses in particular worry that there may be side-effects, that corners have been cut in producing the vaccine and that the generally mild nature of the virus means they don't need to take it. As few as 10%-15% of doctors may have it because we doctors believe ourselves to be above such trivial things as infections."

A poll by Nursing Times magazine last week showed that the proportion of nurses who do not intend to get vaccinated has risen from 31% in August to 47%, while those who definitely will has fallen from 35% to 23%.

Dame Christine Beasley, the chief nursing officer for England, responded by stressing that the vaccine is "as safe as a vaccine can be" and adding: "Nothing in life is risk-free. I can well understand people being worried. I can well understand people thinking it's only a mild illness and why should I bother? I do understand all that, I think you wouldn't be human if you didn't think that." Beasley wants directors of nursing to act as role models to allay concerns among frontline nurses.

Hospital chief executives say privately that Donaldson's repeated reminders of the mild nature of swine flu's effects in those who contract it, and recent claim that the UK is "tantalisingly close" to beating the virus, may be leading staff to believe that vaccination is not important.

The health department said: "Frontline healthcare workers will be absolutely crucial in the height of a pandemic – without them, patient care will suffer, and the NHS will be stretched. Getting the swine flu vaccine will protect them and their patients."

It added: "All NHS organisations will be working hard to ensure that all eligible staff have the choice to protect themselves and their patients from swine flu by having the vaccine."

SPIEGEL Wissenschaft

Junge Patienten für Schweinegrippe besonders anfällig

Spiegel, 12 Oktobre 2009, 16.25 Uhr

https://www.spiegel.de/wissenschaft/medizin/h1n1-infektion-junge-patienten-fuer-schweinegrippe-besonders-anfaellig-a-654684.html

Kanadische Mediziner warnen davor, dass die Schweinegrippe gerade jüngere Patienten besonders schwer treffen kann. Deutsche Kollegen fordern derweil einen Impfstoff für Kinder und Jugendliche, der keine umstrittenen Hilfsstoffe enthält - so wie ihn die Bundeswehr gerade für ihre Soldaten bestellt hat.

Frankfurt am Main - Bislang ist die Schweinegrippe bei den meisten Patienten in Deutschland milde verlaufen, bislang gab es zwei Todesfälle von H1N1-Infizierten, beide Patienten hatten jedoch noch weitere gesundheitliche Probleme. Im einen Fall bestätigten Mediziner, dass tatsächlich das Virus die Todesursache gewesen war. Nun warnen kanadische Mediziner davor, dass das H1N1-Virus gerade bei jungen Menschen dramatische und lebensbedrohliche Beschwerden verursachen kann.

Krankenhäuser

Im "Journal of the American Medical Association" berichten Forscher um Anand Kumar vom Health Sciences Centre and St. Boniface Hospital in Winnipeg über den Krankheitsverlauf von 168 Patienten. => https://jamanetwork.com/journals/jama/fullarticle/184799?resultClick=1 Sie waren zwischen Mitte April und Mitte August wegen besonders schwerer Beschwerden in gebracht worden - und zwar nachdem sie bereits zu Hause im Durchschnitt vier Tage lang Grippesymptome gezeigt hatten. Anschließend habe sich ihr Zustand jeweils rapide verschlechtert.

Der Sauerstoffgehalt des Blutes war extrem gering, bei vielen der Patienten versagten mehrere Organe. Rund 80 Prozent der besonders stark betroffenen Grippeopfer wurden längere Zeit künstlich beatmet. 24 Personen starben innerhalb der ersten vier Wochen, fünf weitere in den folgenden zwei Monaten. Das Durchschnittsalter der Patienten war mit 32 Jahren auffällig niedrig.

"Unsere Daten deuten darauf hin, dass schwerer Krankheitsverlauf und Todesfälle sich bei relativ gesunden Heranwachsenden und Erwachsenen zwischen zehn und 60 Jahren häufen", schreiben die Mediziner. Diese Altersverteilung gleiche jener der Spanischen Grippe von 1918, die ebenfalls durch den Influenzatyp H1N1 verursacht wurde. In der gleichen Zeitschrift kommen Untersuchungen aus , und zu ähnlichen Ergebnissen.

Streit um die Adjuvantien

Unterdessen fordern Kinderärzte in Deutschland auch für ihre jungen Patienten einen möglichst verträglichen Impfstoff gegen die Schweinegrippe. Ein Impfstoff ohne Zusätze wie in den USA solle auch Kindern zur Verfügung gestellt werden, verlangte der Präsident des Berufsverbandes der Kinder- und Jugendärzte (BVKJ), Wolfram Hartmann.

In Europa sind nach Angaben des Bundesgesundheitsministeriums inzwischen drei unterschiedliche Impfstoffe zugelassen, darunter auch einer ohne wirkungsverstärkende Zusatzstoffe, sogenannte Adjuvantien. In den vergangenen Wochen hatten Kritiker wiederholt darauf verwiesen, dass der in den USA im September zur Anwendung freigegebene H1N1-Impfstoff verträglicher sei als der von der Bundesregierung bestellte, in dem sich Adjuvantien finden.

Unter anderem hatte der Ärztliche Direktor des Gemeinschaftskrankenhauses Witten-Herdecke, Stefan Schmidt-Troschke, erklärt, der für Deutschland georderte Impfstoff enthalte Verstärker, die das der bei der relevanten Zielgruppe, nämlich jungen Menschen, Schwangere und Kinder, stark schwächen könne.

Bundeswehr

Die hat, wie am Montag bekannt wurde, ein eigenes Kontingent an Schweinegrippe-Impfstoff bestellt. Er enthält keine Zusatzstoffe. Zielgruppe sind Soldaten im Auslandseinsatz. Vor einem Einsatz im Ausland bekämen die Soldaten je nach den dortigen Ansteckungsmöglichkeiten oftmals gleich eine ganze Reihe von Impfungen. Um ihre Gesundheit zu schützen und "die Durchhaltefähigkeit sicherzustellen", erhielten sie einen "sehr umfassenden Impfschutz, der weit über die Erfordernisse im Inland hinausgeht", erklärte der Sanitätsdienst der Bundeswehr.

Impfstoff für den Auslandseinsatz

Dabei sei es wichtig, auf die wechselseitige Verträglichkeit mit anderen Impfstoffen zu achten. Wären zum Beispiel überall Zusatzstoffe enthalten, "und die kumulieren sich und vertragen sich nicht miteinander", werde es problematisch, sagte ein Sprecher. Daher habe die Bundeswehr einen Impfstoff ohne Konservierungsstoff und Adjuvantien bestellt. "Wir sind nicht was Besseres, sondern wir sind was Anderes", sagte der Sprecher des Sanitätsdienstes.

Kinder- und Jugendmediziner Hartmann hatte dem "Westfalen-Blatt" gesagt, die Ständige Impfkommission habe den Alleingang der Bundeswehr mit Verwunderung zur Kenntnis genommen. Die hatten Anfang Oktober beschlossen, lediglich für Schwangere zusätzlich ein Serum ohne Adjuvantien zu beschaffen.

Ein Sprecher des Bundesgesundheitsministeriums betonte, die derzeit drei in der EU zugelassenen Impfstoffe seien sämtlich sicher. Die von den Ländern für die Zivilbevölkerung bestellten Impfstoffe seien ebenso wirksam wie der Impfstoff der Bundeswehr.

Nach Einschätzung der ist eine Impfdosis pro Person ausreichend. Alle Daten würden darauf hindeuten, dass eine genüge, erklärte die Chefin der WHO-Impfforschung, Marie-Paule Kieny. Die europäische Gesundheitsbehörde EMEA empfahl zuletzt, zunächst jeder Person zwei Mal im Abstand von drei Wochen eine Dosis zu verabreichen. In Deutschland stehen ab Ende Oktober 50 Millionen Dosen des Impfstoffes vom Pharmahersteller GlaxoSmithKline bereit.

netzeitung.de

Schmidt versteht Aufregung um Impfstoff nicht

NetZeitung, 12 Oktobre 2009, 16:31
https://web.archive.org/web/20091015045615/http://www.netzeitung.de/gesundheit/1489979.html

In knapp zwei Wochen sollen die Impfungen gegen die Schweinegrippe losgehen, doch es wächst die Sorge um die Sicherheit der Impfstoffe. «Unbegründet», sagt Ministerin Schmidt. Der Virologe Kekulé ist da anderer Meinung.

Nachdem Soldaten der Bundeswehr einen anderen Impfstoff gegen die Neue Grippe bekommen sollen als der Rest der Bevölkerung, versucht die scheidende Gesundheitsministerin Ulla Schmidt Bedenken um die Sicherheit der Immunisierungen zu zerstreuen: «Die Aufregung, die da heute entstanden ist, ist mit überhaupt nichts zu rechtfertigen», sagte Schmidt am Montag vor einem Treffen mit den anderen EU-Gesundheitsministern in Luxemburg.

Alle Impfstoffe gegen das neue Influenzavirus A/H1N1 seien sicher, getestet und könnten eingesetzt werden. Es gebe aber unterschiedliche Einsätze, ergänzte die Ministerin. Zum Beispiel könnten Schwangere mit einem Präparat ohne Zusatzstoffe («nicht-adjuvantiert») geimpft werden. Die deutschen Behörden hätten bei drei unterschiedlichen Herstellern bestellt und «das Unternehmen, bei dem die Bundeswehr bestellt hat, hat eben einen nicht-adjuvantierten Impfstoff», sagte Schmidt.

Mit Kanonen auf Spatzen

Der hallesche Virologe Alexander Kekulé sieht das allerdings nicht ganz so problemlos und hat Bundesregierung und Ländern vorgeworfen, den falschen Impfstoff gegen die Schweinegrippe eingekauft zu haben. Der Direktor des Instituts für Medizinische Mikrobiologie des Universitätsklinikums Halle sagte am Montag dem Radiosender MDR Info, der im Impfstoff enthalte Verstärker habe erhebliche Nebenwirkungen.

Dieses Mittel wäre im Prinzip gut gegen ein «gefährliches Virus wie die Vogelgrippe», gegen die Schweinegrippe sei es aber «völlig übertrieben». Man schieße gewissermaßen mit Kanonen auf Spatzen, sagte Kekulé.

Viel geeigneter sei der Impfstoff, für den sich die Bundeswehr entschieden habe. Dieser werde auch in den USA und in anderen Teilen der Welt eingesetzt. Er habe keinen Verstärker und funktioniere genauso wie der normale saisonale Grippe-Impfstoff. Der Vorteil dieses klassischen Serums sei, dass es sich schon milliardenfach bewährt habe. Jahrzehntelange Erfahrungen zeigten, dass es kaum Nebenwirkungen gebe.

Die Sprecherin des für Arzneimittelsicherheit zuständigen Paul-Ehrlich-Instituts (PEI), Susanne Stöcker verteidigte die Verstärkerstoffe im bestellten Schweinegrippeimpfstoff. «Grundsätzlich ist die Verträglichkeit gleichwertig, und der Stoff erfüllt alle EU-Kriterien.» Auch die Quecksilberverbindung zur Konservierung der Impfstoffe stelle keine Gefahr da. Das verwendete Thiomersal enthalte kein Quecksilber wie im Fieberthermometer, sondern eine organische Quecksilberverbindung. Die Menge sei wesentlich kleiner als die, die eine Schwangere pro Woche aufnehmen dürfe, ergänzte Stöcker.

YAHOO! DEUTSCHLAND NACHRICHTEN

Soldaten bekommen angeblich besondere Schweinegrippe-Impfung
[Soldiers are said to be given special swine flu vaccinations]

Yahoo Deutschland, 12 Oktober 2009, 10:00 Uhr
https://web.archive.org/web/20091015223830/http://de.news.yahoo.com/2/20091012/tts-soldaten-bekommen-angeblich-besonder-c1b2fc3.html

Die Bundeswehr hat einem Zeitungsbericht zufolge für ihre 250.000 Soldaten einen eigenen Impfstoff gegen die Schweinegrippe bestellt. Anders als das Serum, das der Zivilbevölkerung als Schutz gegen die Infektionskrankheit geimpft werden solle, enthalte der verträglichere Impfstoff für die Soldaten weder umstrittene Zusatzstoffe noch quecksilberhaltige Konservierungsmittel, berichtet das Bielefelder "Westfalen-Blatt" unter Berufung auf Bundeswehrkreise. Es handele sich um das Serum Celvapan des Pharma-Herstellers Baxter.

Die Ständige Impfkommission habe den Alleingang der Bundeswehr mit Verwunderung zur Kenntnis genommen, sagte der Präsident des Berufsverbandes der Kinder- und Jugendärzte, Dr. Wolfram Hartmann, dem "Westfalen-Blatt". Die Gesundheitsminister der Bundesländer hatten den Angaben zufolge jüngst beschlossen, ein Serum ohne Zusätze lediglich für Schwangere zu bestellen. Ärzte hätten vor angeblich unkalkulierbaren Nebenwirkungen bei den von der EU zugelassenen Impfstoffen Pandemrix vom britischen Pharmakonzern Glaxo-Smith-Kline und Focetria vom Schweizer Pharmaunternehmen Novartis gewarnt.

German Soldiers get Additive Free Swine Flu Shot
Troops get access to shot without mercury

Prison Planet, 13 October 2009
https://web.archive.org/web/20091016221658/http://www.prisonplanet.com/german-soldiers-get-additive-free-swine-flu-shot.html
https://web.archive.org/web/20091016235302/http://www.fightbackh1n1.com/2009/10/german-soldiers-to-receive-different.html

According to a report out of Germany, German soldiers have been given an additive-free swine flu shot that doesn't contain mercury, squalene, or any of the other dangerous adjuvants associated with the vaccine, raising questions as to why this version of the shot has not been made available to the general population.

An article that when translated is entitled, *German soldiers gets non poisonous vaccine*, explains how 250,000 German troops have been given a "friendly" vaccine made by Baxter that does not contain "controversial mercury-containing additives or preservatives".

It appears that there are two versions of the swine flu shot, one for those in the know and another for the general population who trust the government to shoot them up with dangerous toxins that have been linked to autism and other neurological disorders.

Despite concerns about thimerosal and mercury, thimerosal is an ingredient of the swine flu vaccine which is currently being rolled out globally.

"Some of the vaccine will be stored in multi-dose vials containing thimerosal, an antibacterial additive that contains mercury," reported the Washington Post in an article about which groups will receive the swine flu vaccine first.

Indeed, the swine flu vaccine contains no less than 25,000 per cent the amount of mercury considered safe.

Mercury is classified by The Department of Defense as a hazardous material that could cause death if swallowed, inhaled or absorbed through the skin, and the EPA is now limiting mercury emissions from factories because the toxin "can damage the brain and nervous system and is especially dangerous to fetuses and small children," but according to the CDC it's perfectly safe to inject into your child's bloodstream.

As we previously highlighted, many people are choosing to take the nasal spray version of the vaccine in the false assumption that it is safer than the injectable version. In reality, the nasal spray contains live H1N1 virus, which has led many doctors and health professionals to express concerns that it could spread the swine flu virus amongst those with weakened immune systems.

"It has been documented that the live viruses from the vaccine can be shed (and potentially spread into the community) from recipient children for up to 21 days, and even longer from adults. Viral shedding also puts breastfeeding infants at risk if the mother has been given FluMist," writes Dr. Sherri Tenpenny, one of the most outspoken physicians in the country on the hazards of vaccines and vaccination.

FluMist's own package insert reads as follows, "FluMist® recipients should avoid close contact with immunocompromised individuals for at least 21 days."

"The warning is specifically directed toward those living in the same household with an immunocompromised person, but the on-going release of live viruses throughout the community may be a significant risk to everyone who has a weak, or weakened, immune system," writes Tenpenny, pointing out that if one takes into account a plethora of health conditions that could be classified as contributing to immunodeficiency, as much as 60% of the entire population could be considered to be "chemically immunosuppressed."

One of the pharmaceutical companies developing nasal spray vaccines is Baxter International, who were caught earlier this year releasing batches of vaccines from a lab in Austria that were contaminated live bird flu virus, otherwise known as H5N1.

THE FLU CASE

"Swine flu" vaccine bracelets report

The Flu Case, 13 October 2009, 20:51
https://web.archive.org/web/20091017025855/http://www.theflucase.com/index.php?option=com_content&view=article&id=1022:qswine-fluq-vaccine-bracelets-report-update&catid=1:latest-news&Itemid=64&lang=en

We have published a few interesting reports about metal bracelets, said to be planned to be used to mark those who have received the "swine flu" vaccine. After having published another piece of information, the person who was the origin of the report made a comment on the article on this site. According to this person, there was a recent delivery to a hospital in the USA and we have now been sent the following:

"We are moving forward with a records request on this basis:

Who ordered them?
Who paid for them?
Where are they?
What is the purpose of them?
When are they to be given out?
What information will they contain?
Why do they need RFID chips?
Request for photos/sample

The Montrose hospital is a public/county hospital which is therefore responsible to the citizens first.

This is a huge deal and no-one to date has had even this information on the bracelets. I am on "high level" speaking terms with the person who signed for these bracelets and he had no "look at me" reason to tell me what he did. He did it to confirm the story that was out there about how they might be used and said matter if fact I signed for a shipment of half a semi last week. And also voiced I and my family would have them when the time came. He is a huge advocate of the NWO and can be a great benefit to getting this story out.

After the records request I will get a sample or image to you but in the meantime you need to keep this story active at the top of the list on the front page. We want others to talk about bracelets at their hospital. They have been delivered all across the country and possibly the world and this is utter proof that this vaccination is only being done to control the world and rfid the population.

This can be the biggest story out there and if you keep it alive this will open another 30 million eyes about the "euginics's" alternative means to giving you the shot. I belive the shot will sterilize and introduce cancer cells to all to take it.

This will help raise awareness and I will do whatever I can from this end. It cannot come back on me. It means my wife's job and I and the community around me have too much to lose if I am mentioned and targeted."

Department of Health
Information for a Healthy New York

Testimony by Guthrie Birkhead, M.D., M.P.H.
Deputy Commissioner New York State Department of Health

Department of Health, New York, 13 October 2009
https://web.archive.org/web/20090925160838/http:/www.cdc.gov/vaccinesafety/vsd/thimerosal_outcomes/

Presented to Assembly Standing Committee on Health, on Labor, on Education, on Higher Education, and on Workplace Safety.

Assemblyman Gottfried, Assemblywoman John, Assemblywoman Nolan, Assemblywoman Glick and Assemblyman Lancman: thank you for the opportunity to testify today and present the New York State Department of Health's response to the 2009 H1N1 influenza. I am Dr. Guthrie Birkhead, Deputy Commissioner for Public Health at the New York State Department of Health.

Our response to H1N1 influenza this fall has benefited from experience with this virus last spring and summer, three years of pandemic influenza planning from 2006 to 2008, as well as our experience with the 2004 flu vaccine shortage and our general state of preparedness to deal with all hazards from weather events, to disease outbreaks, to possible terrorist events. We have learned that our response to public health problems like H1N1 is very dependent on the cooperation and joint activities of the state health department, other state agencies, local health departments, and other partners throughout the health care system. This collaboration is one of the strengths of our public health system in New York.

Last April New York Governor David Paterson directed the state health department to activate its health emergency preparedness plan in response to cases of H1N1 in NYS. This plan was developed over a number of years of pandemic planning and involves the collaboration of programs across the health department, other state governmental agencies and local public health departments. Over the past months both Governor Paterson and Commissioner of Health Daines have been involved in the response with public appearances, multiple press conferences and meetings with providers and consumers.

The primary activities during the H1N1 response have included implementation of targeted surveillance and laboratory testing activities and multiple communication strategies including a toll-free hotline available 24/7, and ongoing communications with county health departments, hospitals, clinics, doctors' offices, schools and other partners. Governor Paterson directed his agencies to develop a coordinated response and supported conduct of a series of town hall style meetings at locations throughout the State to provide in-person briefings on clinical care, surveillance, community mitigation, vaccine and education and outreach.

We learned many lessons from the spring but we still have a lot to learn. We have learned that H1N1 is not a "1918" style pandemic in terms of clinical severity. The clinical spectrum of H1N1 is more similar to seasonal flu than the flu seen in 1918. We have also learned that there is little background immunity to H1N1 in the general population. As a result H1N1 spreads rapidly in children and young adults. Pregnant women have been identified as a population at increased risk of severe complications and as a result are a priority group for vaccination. Unlike the seasonal flu, we have seen relatively little infection in the elderly population suggesting that they may have some immunity possibly as a result of past exposures. With widespread transmission, it is inevitable that some people with underlying medical conditions will experience severe illness and risk death. It is important to note that seasonal flu kills on average 2000 New Yorkers each year; we can expect H1N1 to have a similar impact.

Current H1N1 flu activity

Nationally influenza activity attributed to 2009 H1N1 viruses increased during September 2009 beginning in the southern states where school starts in early August. H1N1 is expected to continue through the fall and winter influenza season. In New York State, our surveillance systems outside New York City indicate that flu activity is starting to increase. New York's flu activity is currently classified as widespread under the CDC's classification system indicating that more than 50 percent of reporting jurisdictions indicate the presence of flu. New York's flu status has gone from sporadic to localized to regional activity to now widespread activity over the last four weeks. To date this fall, the number of people hospitalized with flu remains low but may be starting to increase. Rates of visits for influenza-like-illness are also increasing in Emergency Departments and sentinel providers. So far this fall there have been three known H1N1 associated deaths. There is at least one school district upstate with significant disease and several college campuses have reported disease with one death in a college student.

We may now be at the beginning of our third influenza season this year, the seasonal flu season last February and March, the H1N1 outbreak in May and June, and now the return of H1N1. However, we don't know for sure how the fall and winter flu seasons will unfold. A telephone survey conducted in New York City last spring found that between 6 and 10 percent of all New Yorkers surveyed had experienced influenza-like-illness. The spring flu outbreak may have been truncated by the end of school and the beginning of the warm weather season. Had the flu season continued, as it now appears it may do over the coming fall and winter months, we could possibly see up to 35 to 40 percent of the population impacted by the new flu strain - two to three times that which we experienced in the spring. The experience with flu in states in the southern part of the country suggests a surge three to four weeks following the start of the school year. We are just entering that period in New York State

It should be noted that some cities are reporting near-normal levels of flu activity for this time of year. The cities, including New York, are those that were hardest hit at the outset of the 2009 H1N1 flu pandemic. New York, which had widespread school closures in the spring, is reporting normal attendance; the same holds true for Boston and Philadelphia. One theory to explain the relative lack of flu in these cities – as opposed to the rest of the country where activity is widespread – is that the earlier outbreaks conferred enough "herd immunity" to protect them now. This theory is plausible; only time would tell whether it's accurate.

New York State tracks and evaluates flu prevalence and severity using a multi-faceted reporting system. Five different reporting mechanisms are used to track the flu including an electronic clinical laboratory reporting system which feeds laboratory reports of H1N1 directly to the state; hospital reporting of emergency department visits for influenza-like-illness and hospitalized influenza cases; reports by physicians of patient visits for influenza like illness at selected offices around the state; deaths associated with influenza like illness; and prescriptions filled for antiviral medications. The results of this reporting system are on the Health Department website with statistics updated each week.

H1N1 Vaccine Efficacy and Safety

One of the remarkable aspects of the H1N1 influenza response has been the development of vaccines to prevent it. Influenza A (H1N1) 2009 monovalent vaccines have been developed by the five manufacturers of seasonal flu vaccine. The production and licensure of the H1N1 vaccines are being done by exactly the same methods as the seasonal vaccines. One hundred million Americans are vaccinated each year with seasonal flu vaccines, so the safety and efficacy of the process is well defined. FDA licensure has been on the basis of standards developed for vaccine strain changes for seasonal influenza vaccines, adherence to manufacturing processes, product quality testing, and lot release procedures developed for seasonal vaccines. The age groups, precautions, and contraindications approved for the influenza A (H1N1) 2009 monovalent vaccine are identical to those approved for seasonal vaccines. The only difference between the seasonal and 2009 H1N1 influenza vaccines is the viral antigens contained in the vaccine, which also do vary from year to year as the seasonal vaccine changes. The only other difference is that clinical trials have been done on the H1N1 vaccines to establish the dosing requirements. Clinical trials are not typically done for the seasonal vaccine. So we actually know more about the characteristics of the H1N1 vaccine than we do the seasonal vaccine from these trials.

Preliminary data from the clinical trials indicate that the immunogenicity and safety of these vaccines are similar to those of seasonal influenza vaccines. An immunogenicity study of an inactivated influenza A (H1N1) monovalent vaccine manufactured by CSL Limited demonstrated a safety profile consistent with results from studies of the seasonal influenza vaccine manufactured by CSL Limited. Studies of other seasonal inactivated influenza vaccines found that rates of adverse events were not significantly different from placebo injections except for arm soreness and redness at the injection site. Vaccine safety data are reviewed by both the manufacturers' quality assurance staff and by the FDA. Only when all testing is completed and approved are the vaccines released for distribution.

Clinical trials in children coordinated by the National Institutes of Health reported preliminary results of a study among children aged 6 months--18 years which found safety results to be similar to those observed for seasonal influenza vaccine.

To assure that the safety of the H1N1 vaccine, New York is participating in expanded federal programs to monitor any possible adverse outcomes through a nationwide reporting system known as VAERS (vaccine adverse event reporting system) as well as through a program using managed care data on large populations to conduct follow up of vaccinated persons and a separate CDC-sponsored program to report Guillian-Barre Syndrome cases.

Availability of supplies and H1N1 vaccine distribution

There are currently 4 companies that are fully licensed by the FDA (the 5th is in process) to make the 2009 H1N1 vaccine, the same as for seasonal flu. Med Immune, which makes the inhaled live, attenuated influenza vaccine, Novartis, sanofi pasteur and CSL Limited, which make inactivated influenza vaccine, which is administered through an injection.

The CDC estimates that between now and the end of November there will be over 80 million doses of flu vaccine made available to states throughout the nation for redistribution to localities, health care providers and others as appropriate. The vaccine and supplies being made available by the Federal Government are being dispensed in weekly allotments that vary in size between 1.5 million and 4 million doses each week. States and cities were able to place their first orders for the 2009 H1N1 vaccine on Wednesday September 30th. By October 2nd, 2.4 million doses of live attenuated 2009 H1N1 vaccine were available for ordering with more vaccine becoming available for ordering in the coming days and weeks.

H1N1 Vaccine Distribution

Each week New York State (like all states) is provided a number of doses that are available to us to order. In general we expect to receive approximately 6 percent of the national allotment based on our population. To date we have placed orders requesting our full allotment and have provided direction to the CDC regarding where the vaccine is to be shipped. Our initial ship-to sites focused on hospitals, local health departments and federally qualified health centers – in an effort to assure that all persons in New York State who fit into one of the CDC's Advisory Committee on Immunization Practices (ACIP) defined priority groups have access to vaccine as quickly as possible.

The ACIP defined the following five populations as priority groups for vaccination against H1N1: pregnant women, persons who live with or provide care for infants aged < 6 months (e.g., parents, siblings, and daycare providers), health-care and emergency medical services personnel, persons aged 6 months – 24 years, and persons aged 25--64 years who have medical conditions that put them at higher risk for influenza-related complications. Individuals in these groups are either at higher risk of complications associated with the flu or are more likely to come into contact, and possibly infect, persons at high risk of complications.

These five target groups comprise an estimated 159 million persons in the United States and 10 million people in New York State. Using season flu vaccination rates as a guide, which indicate that 20 to 40% of eligible persons actually present for vaccination, we estimated that we would need at least 4 million doses of H1N1 to reach all New Yorkers who fall into one of the priority groups.

To ensure distribution of vaccine in the most efficient and effective manner the Governor directed the New York State Department of Health to begin the process with initial shipments to all hospitals in the State, to all local health departments (outside of New York City) and to all Federally Qualified Health Centers outside of New York City. Following this initial push we will provide vaccine based on orders submitted by providers who have agreed to vaccinate individuals beginning with those in the defined priority groups.

The first orders, placed two weeks ago were delivered last week. Initial availability of vaccine was limited and included 91,000 doses of LAIV upstate. LAIV is used for 1) healthy kids 2-24 years old and 2) healthy adults 25-49 who are health care workers or who care for children under 6 months. Factors that we have and will continue to take into account when filling orders for H1N1 include: geographic distribution to ensure statewide coverage; per capita allocation amounts (to be equitable in distribution); ability of providers to access target groups; input of local health departments and targeting based on the specific type of vaccine available and the most appropriate target audience.

Additional orders for 113,400 doses of vaccine were placed last week that are expected to arrive at designated sites this week – bringing the total number of H1N1 vaccine doses ordered to date to 204,000. This is only the beginning of what is expected to be available with substantial supplies of H1N1 vaccine being available starting this week and next. We anticipate that by early November, most providers who want to order vaccine will be able to do so. Additional vaccine will roll out through November, December and into January. One of the critical messages we need to convey is that as this vaccine is just now being produced, people and providers need to be patient as we do our best to ensure that vaccine is first delivered to those in the priority groups.

The State Department of Health developed a system to pre-register all providers in the state who are interested in receiving vaccine. This pre-registration process asks that the provider indicate how many people

they anticipate vaccinating and how many of these individuals are in each of the targeted groups – information that will be critical in assuring that vaccine is properly targeted. Eventually we anticipate that all New Yorkers who wish to receive the vaccine will have an opportunity to do so.

To date 4000 providers have pre-registered representing a range of specialties and provider types including private practice physicians, hospitals, local health departments, federally qualified health centers, pharmacies, colleges and universities, public health clinics, substance abuse treatment clinics and Indian health providers. We anticipate that additional providers will register over the coming weeks. We are also aware that there are providers who continue to be concerned with the safety of the vaccine and as a result are reluctant to register and participate in our vaccination efforts. We will continue to work with our partners in the health care community including professional organizations to educate providers as to the safety of the vaccine and the importance of vaccine as a mechanism to assure public health.

EUROPEAN MEDICINES AGENCY
SCIENCE MEDICINES HEALTH

Press release:
GlaxoSmithKline withdraws its marketing authorisation application for Zunrisa

EMeA, 13 October 2009
https://web.archive.org/web/20091015120044/http://www.emea.europa.eu/humandocs/PDFs/EPAR/zunrisa/63959809en.pdf

European Medicines Agency
Press office

London, 13 October 2009
Doc. Ref. EMEA/639598/2009

PRESS RELEASE
GlaxoSmithKline withdraws its marketing authorisation application for Zunrisa (casopitant mesilate)

The European Medicines Agency has been formally notified by GlaxoSmithKline Research and Development Limited of its decision to withdraw its application for a centralised marketing authorisation for the medicine Zunrisa (casopitant mesilate), 50 mg and 150 mg film coated tablets.

Zunrisa was expected to be used in the prevention of post-operative nausea and vomiting and chemotherapy-induced nausea and vomiting.

The application for the marketing authorisation for Zunrisa was submitted to the Agency on 2 July 2008. At the time of the withdrawal, it was under review by the Agency's Committee for Medicinal Products for Human Use (CHMP).

In its official letter, the company stated that the withdrawal of the application was based on the company's assessment that further safety data would be required to support the registration of casopitant on a worldwide basis and that it would take considerable time to produce these data. The company further stated that consequently all ongoing applications for authorisation are being withdrawn.

More information about Zunrisa and the state of the scientific assessment at the time of withdrawal will be made available in a question-and-answer document. This document, together with the withdrawal letter from the company, will be published on the Agency's website after the next CHMP meeting of 19-22 October 2009.

-- ENDS--

Notes:

1. Withdrawal of an application does not prejudice the possibility of a company making a new application at a later stage.
2. This press release, together with other information on the work of the European Medicines Agency, can be found on the Agency's website: www.emea.europa.eu

THE FLU CASE

GSK forced to withdraw new drug over safety fears

The Flu Case, 14 October 2009 13:32
https://web.archive.org/web/20091019142018/http://www.theflucase.com/index.php?option=com_content&view=article&id=1064%3Agsk-forced-to-withdraw-new-drug-over-safety-fears&catid=1%3Alatest-news&Itemid=64&lang=en

GlaxoSmithKline was forced yesterday to withdraw its application to sell a new drug in the EU because the company could not show it was safe.

GSK is reported in a press release on the European Medicines Agency Website (EMEA) website as saying it "would take considerable time to produce these [safety] data" for Zunrisa, a drug expected to be used to prevent nausea and vomitting.

GSK appears to have been forced to withdraw the Zunrisa drug by the Committee for Medicinal Products for Human Use, which is currently reviewing the drug's safety data.

More information is to be made available soon, says the EMEA press release. =>
https://web.archive.org/web/20091015120044/http://www.emea.europa.eu/humandocs/PDFs/EPAR/zunrisa/63959809en.pdf

"Zunrisa was expected to be used in the prevention of post-operative nausea and vomiting and chemotherapy-induced nausea and vomiting.

The application for the marketing authorisation for Zunrisa was submitted to the Agency on 2 July 2008. At the time of the withdrawal, it was under review by the Agency's Committee for Medicinal Products for Human Use (CHMP).

In its official letter, the company stated that the withdrawal of the application was based on the company's assessment that further safety data would be required to support the registration of casopitant on a worldwide basis and that it would take considerable time to produce these data. Carina Bergfeldt

Vaccinberg i Sverige

Aftonbladet, 14 October 2009
https://www.aftonbladet.se/nyheter/a/0EvA5o/vaccinberg-i-sverige

"Jag är fullständigt rättslös"
Fettdoktorn Annika Dahlqvist har nyligen varit i blåsvädret för flera kontroversiella uttalanden. Och nu får hon sparken från jobbet som jourvikarierande läkare i Västernorrland. Anledningen: hennes åsikter om vaccinering mot svininfluensan och mammografi.

Annika Dahlqvist blev under en föreläsning i Luleå i tisdags uppringd av en sköterska på en vårdcentral i Sundsvall.

Dahlqvist fick beskedet att primärvårdsdirektören Lennart Moberg beslutat att Dahlqvist inte längre ska anlitas som läkarvikare.

Hon får sparken för sina uttalanden om att en fettrik kost gör influensavaccination, cellprovtagning och mammografi onödiga.

– Det är ingen som talat med mig, jag känner mig fullständigt rättslös, säger Dahlqvist.

"Anmärkningsvärda synpunkter"

– Som jag förstår det är jag spärrad från alla arbetsplatser i primärvården i Landstinget Västernorrland. Det är väl ingen som vågar anställa mig på en vårdcentral nu.

Lennart Moberg, primärvårdsdirektör vid primärvården Västernorrland, säger att Dahqvist inte blivit uppsagd – eftersom hon inte har någon anställning.

– Men efter hennes anmärkningsvärda synpunkter och ifrågasättanden av medicinskt evidensbaserade arbetsmetoder, som cellprovstagning, vill vi inte att hon fortsätter som timvikarie.

THE FLU CASE

Unwanted vaccine piles up in Sweden

The Flu Case, 14 October 2009, 08:57
https://web.archive.org/web/20091018051450/http://www.theflucase.com/index.php?option=com_content&view=article&id=1024%3Avaccine-mountain-in-sweden&catid=1%3Alatest-news&Itemid=64&lang=en

Mass vaccinations against the highly questioned so-called "swine flu" have started in Sweden and the hard reality of this mistake is now confronting everyone involved. One big issue for politicians seem to be that they have signed a contract which forced them to purchase a certain amount of vaccine as soon as the WHO declared pandemic level 6. Now, with a mild so-called "swine flu" and a vaccine-hesitant popuation, the amount of vaccine ordered will pile up and soon become a political scandal. Especially since less than half of the population intend to get the shot.

Swedish news paper Aftonbladet writes:

Vaccine mountain in Sweden

Sweden has bought two vaccine shots for every citizen. Only one is needed. Now the local authorities are trying to get rid of the unnecessary vaccine mountain.

18 million doses for over one billion SEK (144 million dollars). That is how much swine flu vaccine Sweden is bound to purchase since it was calculated that two doses would be needed per citizen. But yesterday that all changed reports Sveriges Radio (Swedish state radio).

Only one dose

Now, both manufacturers of the vaccine and experts from World Health Organization, WHO, claim that one dose per person will be enough. For Sweden this means unused medication for half a billion SEK (70 million dollars). But Göran Stjernstedt from Sveriges Kommuner och Landsting, SKL, hopes that the vaccine manufacturers will take back some of all the medication.

"- I presume that we can renegotiate with the company since the conditions have changed. The product delivered is another from the one promised when we signed the agreement" he says to Ekot.

So far, 600 000 doses have arrived to Sweden and are being distributed.

THE FLU CASE

Sanofi's Panenza: the secret and safe vaccine for the "elite"?

The Flu Case, 14 October 2009
https://web.archive.org/web/20091018144056/http://www.theflucase.com/index.php?option=com_content&view=article&id=1066:sanofis-panenza-the-secret-and-safe-vaccine-for-the-qeliteq&catid=1:latest-news&Itemid=64&lang=en

Is Sanofi Pasteur's "swine flu" vaccine Panenza, manufactured at the company's facility in Val de Reuil, France, going to be the vaccine of choice of the global "elite", who will be expected, like everyone else, to submit to the WHO/UN push to nanochip every single person in the USA and Europe?

Panenza is a single dose vaccine without adjuvants and without a live virus, which is manufactured using the same process as normal flu vaccines licenced in Europe.

Panenza is not intended to be distributed in the U.S.A where Sanofi Pasteur produces another "swine flu" vaccine licensed by the F.D.A, Sanofi says in a document.

Sanofi Pasteur Press Release

Panenza®* and Humenza®* Influenza A(H1N1) Vaccines Demonstrate Robust Immune Response After One Dose

- Interim data from European studies confirm that one dose of Panenza® or Humenza® pandemic influenza vaccines induces robust seroprotective antibody response in children and adults -

Lyon, France – October 8, 2009 - Sanofi Pasteur, the vaccines division of the sanofi-aventis Group (EURONEXT: SAN and NYSE: SNY), announced today that a single dose of influenza A (H1N1) 2009 monovalent vaccines, Panenza® (15 mcg dose, non-adjuvanted) or Humenza® (3.8 mcg dose, adjuvanted), administered to children (3 years of age and older) and adults induces a robust immune response, according to results from clinical trials conducted in Europe.

One dose of Panenza or Humenza Influenza A (H1N1) 2009 monovalent vaccine induces a robust antibody response that is considered protective in 93 percent or more of adults 18 to 59 years old and in 83 percent or more of adults 60 years of age and older. In children 3 years of age through 17 years of age, 94 percent or more of study participants achieved seroprotective antibody response. Both vaccines tested met the three European Medicines Agency's (EMEA) criteria.

"These significant clinical data concerning Sanofi Pasteur's pandemic influenza vaccines will help build public confidence in the vaccine and will support efforts by health authorities to face the challenge posed by pandemic influenza," said Wayne Pisano, President and Chief Executive Officer of Sanofi Pasteur. *"Humenza and Panenza vaccines are effective answers to different public health needs. Humenza, a low-dose adjuvanted vaccine, has the potential to expand pandemic production capacities and to increase the number of doses of vaccine available, making it possible to immunize more people; Panenza, standard-dose non-adjuvanted vaccine, may be considered by European authorities as the vaccine of choice to protect specific at-risk populations."*

Harper's hedge on H1N1 shot sparks confusion

CBC News, 14 October 2009, 11:45 PM ET
https://web.archive.org/web/20091017061235/http://www.cbc.ca/health/story/2009/10/14/h1n1-research-funding.html

Prime Minister Stephen Harper may have added to the confusion about the H1N1 vaccine on Wednesday by appearing to hedge on whether he would get immunized against the swine flu virus.

But Harper's comments come while the country's top pandemic planners are trying to convince people they should take the shot and that the vaccine is safe.

Harper was asked whether he and his family will get the vaccination against the H1N1 influenza A virus that causes swine flu and when he would like the vaccine to be available.

"My plan, if it's generally recommended for people to get the vaccine, my plan is to get the vaccine," he answered at a news conference near Edmonton on Wednesday.

"But as yet, of course, we haven't actually made a final decision or set a date. We're, as you know, right now, waiting [for] final approval of the vaccine, but we expect that imminently."

Federal public health officials have engaged in what they are calling the largest immunization campaign in history, trying to spread the message that the H1N1 vaccine is the best defence against the disease.

Harper's aides later said the prime minister actually meant he would get the shot if it was approved, not if it was recommended.

Meanwhile, health officials have also been criticized for not getting the vaccine out quickly enough compared with other countries.

At a news conference in Winnipeg to announce H1N1 research funding, Health Minister Leona Aglukkaq said Canada remains on track for getting the H1N1 vaccine in time for health-care workers to administer it starting in the first week of November.

No step will be skipped in the process of testing the safety and effectiveness of the vaccine, she said.

Canada's vaccine approach

Canada's chief public health officer countered criticism of the delay, saying Canada's priority is to target the most vulnerable groups first, such as pregnant women or those with underlying medical conditions, and then to make the vaccine available to everyone who wants it.

"The advantage in Canada that we have is that — while we may not start first with a few people [like other countries] — we will very quickly be able to immunize everybody in Canada who wishes it, in advance of the real peak," said Dr. David Butler-Jones.

Clinical trials are underway to determine how many doses of the vaccine are needed for different age groups, he said.

The U.S. has decided to start by giving a live virus version of the vaccine in nasal spray form first, but it is only an option for healthy adults, Butler-Jones noted.

Australia has started giving H1N1 shots for people over the age of 18 while health officials wait for clinical data on the safety and effectiveness of the vaccine in children, one of the groups at high risk for serious disease.

China only has a tiny amount of vaccine relative to its total population, Butler-Jones told reporters.

But those doses still need to be shipped, nurses and other health-care professionals who administer the vaccine need to be trained to use it, and mass immunization clinics need to be set up in provinces and territories that put the vaccine into arms — a huge logistical challenge, he said.

Also on Wednesday, Aglukkaq announced another $2.4 million over two years will support five new research projects on the H1N1 flu virus.

The research will be funded through the Canadian Institutes of Health Research.

THE GLOBE AND MAIL

Chinta Puxley

Canadians will get H1N1 shots faster than others: official

The Globe and Mail, Winnipeg, 14 October 2009
https://www.theglobeandmail.com/news/politics/canadians-will-get-h1n1-shots-faster-than-others-official/article4214961/

Canada may be behind other countries in rolling out its swine flu vaccine, but the population should be immunized by Christmas before the virus peaks, the country's chief public health officer said Wednesday.

David Butler-Jones said when the H1N1 vaccine becomes available in early November, Canadians will be immunized faster than people in other parts of the world. In some jurisdictions, such as *Iqaluit, Nunavut*, the population will be immunized *within a matter of weeks*, he said.

"The advantage in Canada that we have is that - while we may not start first with a few people - we will very quickly be able to immunize everybody in Canada who wishes it, in advance of the real peak," Mr. Butler-Jones said after a research funding announcement in Winnipeg.

With health officials pushing everyone to get immunized, Prime Minister Stephen Harper said Wednesday he will be one of those rolling up his sleeve. – "My plan is to get the vaccine," he said at a news conference in Wabamun, Alta. "As yet, of course, we haven't actually made a final decision or set a date. We're awaiting final approval of the vaccine but we expect that imminently."

A Canadian Press-Harris-Decima poll released last week indicated one-third of those surveyed planned to get the swine flu shot.

Canada has been criticized for not getting out the vaccine quickly enough when it is already available in the United States and other countries. The Canadian Medical Association Journal released a modelling study this week that showed vaccine could have a large dampening effect if used early enough to combat a fall wave of H1N1.

But Mr. Butler-Jones said Canada is well-positioned compared with the United States and China. The vaccine used in the U.S. was one intended for healthy people since it contained a small dose of the virus, he said, and the country quickly ran out of that vaccine shortly after it became available.

China doesn't have enough vaccine for its population, Mr. Butler-Jones added.

Three million doses a week will be available in Canada once clinical trials and quality tests are complete, he said. – "What we're aiming for ... is that before Christmas and before we're in the season of sharing - not just good things but viruses as well - that everybody who wishes to be immunized will have had that opportunity."

Mr. Butler-Jones and Health Minister Leona Aglukkaq also announced $2.4-million in funding for five research projects related to H1N1. The cash is to be spent over two years at hospitals in Toronto and Montreal, the University of British Columbia and University of Manitoba.

Projects include studies on why some pregnant women develop complications with swine flu, why some patients develop serious respiratory illnesses, how institutions can handle the most ill patients and new drug therapies for severe H1N1 infections.

Although the largest individual grant works out to be just under $600,000, Ms. Aglukkaq said the research is a "critical part of Canada's pandemic plan."

She continued to urge Canadians to take advantage of the H1N1 vaccine the minute it becomes available. – "My goal is to have 100 per cent of Canadians (vaccinated)," she said. "Immunization is our strongest line of defence against the influenza. Getting vaccinated is the single-most important step you can take to prevent the infection and to stop its spread."

THE FLU CASE

WHO switches out seasonal flu virus strain

The Flu Case, 14 October 2009; 13:31
https://web.archive.org/web/20091018123203/http://www.theflucase.com/index.php?option=com_content&view=article&id=1071%3Awho-switches-out-seasonal-flu-virus-strain&catid=41%3Ahighlighted-news&Itemid=105&lang=en

WHO has recommended the replacement of the current seasonal influenza vaccine strain with a virus that has components of the pandemic H1N1 virus, following a meeting of "experts" from the Global Influenza Surveillance Network.
The decision by WHO to alter components of the H3N2 virus in this years seasonal flu vaccine to make it more similar to a H1N1 pandemic virus will fuel fears that WHO is manipulating the H1N1 virus to increase the likelihood of a pandemic emerging when people take the "swine flu" vaccine soon after their seasonal flu shot.

A French scientist who works for WHO's Global Inflzenza Surveillance Network, Bruno Lina, carried out research this summer into making the "swine flu" more virulent.

In a report published in the French Lyonmag on July 16th, Professor Bruno Lina said he was leading a team at a laboratory located in the "Rockefeller House" in Lyon seeking to find a gene to make the swine flu more virulent.
=> https://web.archive.org/web/20091010034753/http://www.lyonmag.com/article/10958/bruno-lina-la-vaccination-est-le-pilier-de-la-lutte-contre-la-grippe-a

"**What types of research are being carried out by laboratory against the influenza virus**?"

Bruno Lina: "We are seeking to understand the evolution of this virus. And among the scenarios that are possible, there are those concerning the factor of virulence. Work we are therefore carrying out in P4 today relates to the virus H1N 1, into which we are introducing a gene for virulence to see if the latter accepts it and if it becomes the same time more dangerous. At present, the virus has great difficulty to acquire the factor of virulence.»

Lyon Mag.com: Quels types de recherches sont menés au sein du laboratoire contre le virus de la Grippe A ?

Bruno Lina: On essaye d'imaginer l'évolution de ce virus. Et parmi les scénarii qui sont possibles, il y a le facteur de virulence. Les travaux que l'on mène donc aujourd'hui dans le P4 concernent le virus H1N 1, et dans lequel on introduit un gène de virulence pour voir si celui-ci l'accepte et s'il devient du même coup plus dangereux. Pour l'instant, le virus a beaucoup de mal à acquérir le facteur de virulence. Mais notre objectif est d'avoir un coup d'avance par rapport à ce qu'il pourrait se passer dans la nature et d'anticiper l'apparition d'une mutation traitée en laboratoire.

Professor Bruno Lina is the head of the WHO national reference lab in France housed in the Avenue Rockefeller in Lyon, according to Infomed. Direct links to WHO did not work.

THE FLU CASE

French government document ordering military to take "swine flu" jab surfaces

The Flu Case, 14 October 2009, 11:59
https://web.archive.org/web/20091018123403/http://www.theflucase.com/index.php?option=com_content&view=article&id=1050%3Afrench-government-document-ordering-military-to-take-qswine-fluq-jab-surfaces&catid=41%3Ahighlighted-news&Itemid=105&lang=en

Documents from the French Ministry of Interior ordering all members of the Gendarmerie to be given the "swine flu" jab have surfaced in spite of the French government's insistance the jab will be voluntary. => http://changementclimatique.over-blog.com/article-vaccin-h1n1-obligatoire-37475047.html

The French Gendamerie is a military force comprising more than 100,000 personnel that carries out policing duties in more rural parts of the country.The Gendamerie was subordinated to the Ministry of Interior on January 1st, 2009.

Dated September 8th and 10th, the documents outline a plan for the vaccination of all military and civilian members of the Gendamerie by the army medical corps (service de sante des armees.)

The wording makes it clear that all members of the gendamerie will have to submit to a "swine flu" injection by medical teams attached to their units. Families of Gendarmes will be given their jabs in civilian swine flu centers.

The swine flu jabs are to be stored in army facilities in Vitry, Chartes and Marseille before being distributed to the gendamerie units, according to the documents.

Gendarmes are to be given to shots with an interval of 3 weeks.

Significantly, the Gendarmes appear to be set to receive Novartis and GSK shots containing dangerous mercury and squalene, but Baxter and Sanofi shots without mercury and squalene have been ordered and appear to be set to be given to a portion of the personnel.

Baxter and Sanofi shots have been ordered in small quantities by the French government with only 50,000 Baxter shots reported to be available.

The decision to give the personnel serving in the Gendarmes two totally different types of shots will spark fears that the inner circle who are preparing to unleash biological warfare on the people of France on behalf of WHO and the UN have prepared a small number of safe shots for themselves.

Vaccin H1N1 obligatoire
Circulaire du Ministère de l'Intérieur pour la Gendarmerie

Change Mentclimatique, 13 octobre 2009
http://changementclimatique.over-blog.com/article-vaccin-h1n1-obligatoire-37475047.html

Voici les copies d'une note de la direction de la gendarmerie qui prévoit les vaccinations OBLIGATOIRES pour le personnel militaire de la gendarmerie. Alors que Fillon et Bachelot ont annoncé récemment que cette vaccination contre la grippe H1N1 ne serait PAS OBLIGATOIRE.

Note de Ferlin: On peut se dire que ce sont des militaires, donc... Mais ils sont maintenant rattachés au Ministère de l'Intérieur. Et si la vaccination est obligatoire pour eux, elle a de fortes chances d'être décrétée obligatoire en général, dans un proche avenir.

Werner Bartens

Konjunkturspritze für die Pharmaindustrie: Schweinegrippe-Impfung

Süddeutsche Zeitung, 15 Oktobre 2009, 08:24
https://web.archive.org/web/20091017232739/http://www.sueddeutsche.de/wissen/680/491051/text/

Die Impfung gegen das H1N1-Virus ist fragwürdig. Möglicherweise haben nicht nur medizinische Gründe zur Impfempfehlung geführt.

Stell dir vor, es ist Schweinegrippe, und keiner fühlt sich bedroht. Stell dir weiter vor, es gibt eine Impfung, die als bedrohlicher wahrgenommen wird als die Krankheit, vor der sie schützen soll. In dieser paradoxen Situation befindet sich Deutschland derzeit.

Zum Glück erweist sich die Schweinegrippe hierzulande bisher als ziemlich milde. Bei den meisten der 22.000 Infizierten, bei denen H1N1 nachgewiesen wurde, verlief die Erkrankung harmloser als die saisonale Grippe. Wo also ist die Gefahr?

Das Virus könnte plötzlich häufiger schwere Symptome auslösen. Das Virus könnte sich verändern und gefährlicher werden. Das Virus könnte sich mit anderen Viren zu einem Super-Virus vermischen und rund um den Globus eine Spur der Verwüstung hinterlassen.

Alle diese Szenarien sind möglich - sie könnten heute, morgen oder nächstes Jahr tatsächlich Wirklichkeit werden, vielleicht aber auch nie. Zu viele Konjunktive, um sich gefährdet zu fühlen.

Weltweit sind bisher mehr als 350.000 Infektionen mit H1N1 nachgewiesen worden, etwa 4500 Menschen sind an der neuen Influenza gestorben. Auch wenn es unangenehm ist, Todesopfer gegeneinander aufzurechnen, hilft es, sich klarzumachen, dass die saisonale Grippe im Gegensatz dazu jährlich allein in Deutschland 8000 bis 11.000 Todesopfer fordert.

Deutschland war noch nie gut in Risikoeinschätzung. Die sprichwörtliche "German Angst", die von amalgam-sanierten Homöopathiefreunden geäußerte Sorge um das Waldsterben und der Kampf gegen Mobilfunkantennen sind in anderen Weltgegenden als irrationale Marotten dieser seltsamen Teutonen legendär. Deutschland, das Land der Denker und Grenzwerte.

Bundesbehörden, Ministerien und Länderregierungen müssten eigentlich um das Skepsis- und Erregungspotential ihres Volkes wissen. Stattdessen präsentieren sie den Bürgern halbfertige Impfpläne mit halbfertigen Impfstoffen. Die neuen Vakzine sind übereilt hergestellt und an nur wenigen Freiwilligen getestet worden.

Sie sind teilweise mit neuen Wirkverstärkern versetzt, mit denen ebenfalls wenig Erfahrung besteht. Das Risiko der Impfung ist wahrscheinlich nicht sehr groß, aber es lässt sich eben auch nicht ausschließen.

Die Entscheidung für eine Impfung wird meist von beschwerdefreien Gesunden getroffen. Wer sich Schmerzen zufügen und impfen lässt, wägt vorher seinen vermuteten Nutzen und Schaden ab.

Entweder muss die Bedrohung durch die zu verhindernde Krankheit als ausreichend groß erachtet werden oder das Risiko eines Schadens verschwindend gering erscheinen. Beides ist im Fall der Schweinegrippe derzeit nicht gegeben.

Zudem besteht der Verdacht, dass nicht nur medizinische Gründe zur Impfempfehlung geführt haben. Die europäische Zulassungsbehörde ist mehrheitlich von der Industrie finanziert, die meisten Mitglieder der deutschen Impfkommission standen auf der Honorarliste von Pharmafirmen.

Länder und Ministerien haben mit Impfstoffherstellern Geheimverträge geschlossen, den Preis ausgehandelt und die Firmen von jeglicher Haftung freigestellt. Die Logistik der Verteilung ist unklar, wie die Kühlkette aufrechterhalten werden soll, dürfte spannend werden.

Ärzte sind wütend, weil die Impfchargen so groß sind, dass zehn bis zwanzig Patienten am Tag geimpft werden müssen - oder der Rest des Impfstoffs verfällt. Verwirrung stiftet, dass die Bundeswehr (die Bundesregierung auch?) andere Impfstoffe erhält als der Rest der Bevölkerung. Die Impfkampagne ist ein einziges Durcheinander.

Die Zweifel bleiben, sie werden sogar größer. Die vielen offenen Fragen hätten vor der Impfempfehlung erörtert werden müssen - auch wenn dies den Impfbeginn verzögert hätte. Da dies nicht geschehen ist, scheint die Spritze gegen die Grippe vor allem eines zu sein - eine Konjunkturspritze für die Pharmaindustrie.

THE FLU CASE

German mainstream media rips into "swine flu" jab`

The Flu Case, 15 October 2009 13:23
https://web.archive.org/web/20091022091128/http://theflucase.com/index.php?option=com_content&view=article&id=1092%3Agerman-mainstream-media-rips-into-qswine-fluq-jab&catid=1%3Alatest-news&Itemid=64&lang=en

With just days to go until the German government launches its biggest ever mass vaccination programme in history, the country's mainstream media has started to carry reports fiercely attacking the "swine flu" jab, with the mainstream Die Sueddeutsche Zeitung newspaper today reporting on the fury of doctors, the riskiness of jabs and the profits of big pharma.

In a commentary, W. Bartens said the German government was "presenting its citizens with half-baked vaccination plans and half-baked vaccines."

"The new vaccines have been manufactured too quickly and only tested on a few volunteers. Some of them contain the new adjuvants about which we know little as well."

"In addition, there is a suspicion that the recommendation to vaccinate was not just made for medical reasons. The European bodies responsible for authorising medicines are largely financed by industry; most of the members of the German national vaccine commission are on the salary list of pharmaceutical companies. States and Ministries have sealed secret contracts with vaccine manufacturers, negotiated the price and freed companies from all liability. The logistics of the distribution are not clear; to see how the vaccines are going to be kept cool is going to be interesting.

Doctors are furious because the packets of vaccines are so big that ten to twenty patients day need to be vaccined - or the rest of the vaccine has to be thrown away. Another source of confusion is that the German army (the German government too?) is getting another type of vaccine than the rest of the country," says the report, below in German.

THE FLU CASE

Sporthalle Reitweg soll zentrale Impfstelle werden
Bund regelt Impfreihenfolge

Stadt Köln - Amt für Presse- und Öffentlichkeitsarbeit, 15 October 2009

https://web.archive.org/web/20091022084307/http://www.theflucase.com/index.php?option=com_content&view=article&id=1099:gigantic-sports-hall-in-germany-to-be-used-to-vaccinate-15000-people-a-day&catid=1:latest-news&Itemid=64&lang=en

Die Bundesregierung hat gestern eine Rechtsverordnung beschlossen, die den Rahmen steckt für die Durchführung einer freiwilligen Impfung gegen die Neue Influenza A, "Schweinegrippe". Vorrangig sollen chronisch Kranke, Schwangere und Personal im Gesundheitswesen sowie Einsatzkräfte der Polizei und Feuerwehren geimpft werden. Wie die Impfung in Nordrhein-Westfalen im Einzelnen durchgeführt werden soll, wird die Landesregierung regeln. Es bleiben auch noch die Empfehlungen der Ständigen Impfkommission abzuwarten, die berücksichtigt werden müssen. Bis spätestens Mitte September rechnet das Gesundheitsamt der Stadt Köln, dass alle Details vorliegen.

Die Stadt Köln bereitet sich auf diese Impfung mit der Vorbereitung einer zentralen Impfstelle in der Sporthalle am Reitweg in Deutz vor. Dort können bis maximal 15.000 Personen täglich geimpft werden. Diese Impfstelle wurde schon vor fünf Jahren im Rahmen der Pandemieplanung der Stadt Köln getestet und ausgewählt.

Leider müssen die Sportvereine, die diese Sporthalle regelmäßig nutzen, für längere Zeit auf andere Einrichtungen ausweichen. Die Verwaltung ist bereits seit einigen Wochen in Gesprächen mit den Vereinen und den Schulen, die diese Halle auch für den Schulsport nutzen. Es liegen auch Angebote anderer Vereine zu sportlichen Kooperationen vor. In einem weiteren Gespräch heute Mittag mit dem Deutzer Turnverein wurden weitere Alternative vorgestellt. Einem Vorschlag des Deutzer Vereins zu einer teilweisen Unterbringung in den Hallen am Judenkirchhofweg soll so weit wie möglich entsprochen werden. Die Hallen sind derzeit noch nicht in Betrieb, werden jetzt aufgrund der neuen Unterbringungsproblematik allerdings kurzfristig fertiggestellt.

Stadt Köln - Amt für Presse- und Öffentlichkeitsarbe**it** Inge Schürmann

Gigantic sports hall in Germany to be used to vaccinate 15,000 people a day

The Flu Case, 15 October 2009, 14:59

Plans to give up to 15,000 people a day the "swine flu" jab in a sports hall in Cologne are being prepared, according to a press release from the city of Cologne in Germany.

The use of gigantic sports facilities in Germany and the UK to carry out the mass vaccination of populations will heighten fears that the campaign is being carried out for the profit of the pharma industry with little regard for people.

Meagan Fitzpatrick

Swine flu research gets $2.4 M shot in the arm

The Gazette, 15 October 2009
https://web.archive.org/web/20091126181220/http://www.montrealgazette.com/health/Swine+research+gets+shot/2100765/story.html

Medical researchers trying to answer some of the mysteries about the H1N1 virus got a funding boost from the federal government Wednesday worth $2.4 million.

Through the Canadian Institutes of Health Research, five new projects will be funded over the next two years and work on them is beginning "immediately," according to Health Minister Leona Aglukkaq.

"Research tells us critical information about the shape and the direction of this pandemic," she said while making the announcement at the National Microbiology Laboratory in Winnipeg.

The H1N1 pandemic virus is a novel strain that had never been seen before it appeared in the spring and quickly spread around the world.

Because it was new, experts couldn't predict how it would behave and pandemic preparedness plans had to be adjusted as more was learned about the illness.

The majority of cases in Canada have turned out to be mild – the virus has been linked to 79 deaths – but more than 1,500 people have required hospitalization and close to 300 of those patients were in intensive care units.

Often the seasonal flu strikes elderly people and those with underlying and chronic health problems. The H1N1 virus does not appear to strike elderly people as often and is, in fact, causing severe illness in some young and otherwise healthy people. It is also infecting high-risk groups, however, including pregnant women, and researchers are eager to learn why.

One of the five research projects, centred at Mount Sinai Hospital in Toronto, will focus on pregnant women and look at the best ways to reduce infection and why only some pregnant women develop complications.

Researchers at Sunnybrook Health Sciences Centre in Toronto will study how to manage health-care resources during a pandemic, and the team will also focus on determining who is most likely to get sick and how health facilities can better prepare to care for them. There has been a lot of concern in the medical community about what is called "surge capacity" and whether there will be enough personnel and equipment – such as ventilators and beds – to treat a high number of patients.

A third project, at the University of British Columbia, will look into new drug therapies to treat patients with severe infections, while another team at the University of Manitoba will try to determine why some people with H1N1 develop severe illness by looking at how the immune system fights the infection.

In Montreal, researchers will look at immune responses to the H1N1 vaccine.

Speaking to reporters after the announcement, Aglukkaq and chief public health officer Dr. David Butler-Jones reiterated that the H1N1 vaccine will be ready for the first week of November.

There has been mounting confusion and criticism over the last few weeks regarding the timeline for the vaccine's delivery to the provinces and territories. Some critics have argued the pandemic vaccine will come too late to be effective against a second wave of the pandemic and that Canada is lagging behind other countries, such as the United States, that have already begun immunizing their populations.

Aglukkaq also exhorted Canadians to get their flu shots when the H1N1 vaccine becomes available next month.

"At the end of the day, it is an individual choice," she said. "(But) if you don't want H1N1, get the vaccine."

Ottawa plans to run ads in the next several weeks, encouraging Canadians to become immunized, a federal official said Wednesday.

"I guess my biggest concern would be that, you know, we've produced the vaccine, clinical trials take place and then not get the response and then have to deal with the aftermath of that," Aglukkaq said.

"It's really important to get the facts out to ensure Canadians are aware that the medical experts are saying that it's safe, and encourage them to go."

Reports suggesting a significant portion of Canada's medical personnel don't intend to be vaccinated for the pandemic flu concern Butler-Jones.

"Doctors and nurses are not immortal, as much as we might think we are," he said. "And, unfortunately, if we're not immunized, and we have influenza, we'll take it into the nursing home and hospital and, potentially, we'll kill our patients."

"There's an old edict in medicine which is: 'first, do no harm.' So being immunized is really key. And immunization is the safest, most effective, most cost-effective measure in modern medicine.

"My goal is to have 100 per cent of Canadians (vaccinated)," the federal minister told reporters at the lab. "We're very fortunate as Canadians to be able to have that choice."

Butler-Jones repeated his explanation for the November delivery date again Wednesday, saying Canada's vaccine manufacturer, GlaxoSmithKline, had to finish making the seasonal flu vaccine first before starting production of the H1N1 vaccine.

"Postponing the H1N1 in order to complete that was an important thing to do for the protection of Canadians. It would be really sad if we got really good at H1N1 and then had a lot of people needlessly die from seasonal flu," Butler-Jones told reporters.

The annual flu is estimated to be linked with at least 2,000 deaths every year. Flu activity has increased in British Columbia in recent weeks, but across the country there is not widespread illness the way there is in the United States.

The pandemic vaccine is now in production at GlaxoSmithKline's Quebec factory, and Health Canada is awaiting more clinical trial data before it authorizes it for use.

"No step is going to be skipped," the health minister pledged. Once the vaccine is approved, it will be shipped to the provinces and territories and local health authorities will operate immunization programs. The provinces and territories have assured the federal government they can be ready to administer the vaccine to their residents by the first week of November.

Prime Minister Stephen Harper said Wednesday that he will get the shot. "My plan is to get the vaccine," he said at a news conference.

Canadian Health Minister Wants 100% of Population H1N1 Vaccinated
Goal is to get everyone to take the jab before Christmas

Infowars, 15 October 2009

https://web.archive.org/web/20091130074252/http://infowars.net/articles/october2009/151009Canadian.htm

Despite national polls indicating that only one third of Canadians intend to get the H1N1 flu vaccine, a Federal Health Minister says it is the government's goal to vaccinate 100% of the population.

"My goal is to have 100 per cent of Canadians (vaccinated)," chief public health officer Dr. David Butler-Jones told reporters at the National Microbiology Laboratory in Winnipeg.

The minister stated that the vaccine will be rolled out in the first week of November, with the goal of vaccinating everyone by the end of December.

"No step is going to be skipped," the health minister pledged. Once the vaccine is approved, it will be shipped to the provinces and territories and local health authorities will operate immunization programs."

Butler-Jones made the statement at a press gathering to announce a funding boost for swine flu research from the federal government in the shape of $2.4 million.

"At the end of the day, it is an individual choice," he said. "(But) if you don't want H1N1, get the vaccine." Butler-Jones urged.

"We're very fortunate as Canadians to be able to have that choice." he added

Last week a new Canadian Press Harris-Decima poll indicated that only a third of people in Canada intend to take the shot. That figure is down from 45% in a similar poll conducted in August.

Only 11 per cent of respondents described themselves as very concerned about H1N1.

Butler-Jones scolded a portion of Canadian health workers who have also indicated that they do not intend to get vaccinated:

"Doctors and nurses are not immortal, as much as we might think we are," he said. "And, unfortunately, if we're not immunized, and we have influenza, we'll take it into the nursing home and hospital and, potentially, we'll kill our patients."

Baxter sees multiyear opportunity in H1N1 vaccines

Reuters, 15 October 2009, 1:38pm EDT
https://www.reuters.com/article/rbssHealthcareNews/idUSN1529801720091015/?pageNumber=1&virtualBrandChannel=11604
https://web.archive.org/web/20170411134435/http://www.reuters.com/article/flu-baxter-vaccines-idUSN1529801720091015?pageNumber=1&virtualBrandChannel=11604

Chicago, Oct 15 (Reuters) - Baxter International Inc (BAX.N), best known for its drug pumps and products for blood disorders and kidney disease, said it sees a lucrative new revenue source in vaccines and a multiyear opportunity in H1N1 swine flu vaccines.

The hospital products maker said it expects to recognize $30 million to $40 million of revenue from H1N1 vaccines in the fourth quarter. It began shipping the product in August. "We increasingly believe this has the potential to translate into a significant longer-term opportunity for the company," Baxter Chief Executive Robert Parkinson said on a conference call on Thursday.

He declined to speculate on sales beyond the fourth quarter, noting that sales will depend upon many factors, including further improvements in vaccine yields, final dosing regimens and the how bad this flu strain turns out to be.

Baxter has regulatory approval for a two-dose vaccine, but not a single dose. "I think it is fair to say there probably is some increased optimism," Parkinson said of the company's cell culture-based vaccine program -- an alternative to vaccines traditionally produced using chicken eggs.

He said there was some question within Baxter about whether the swine flu pandemic represented a one-time opportunity or a sustainable business. "I think we are increasingly feeling that this is a sustainable business opportunity," he said.

He noted that the World Health Organization recently said it believed that "this is something that governments, in fact the world, are going to have to continue to live with."

Sanofi-Aventis (SASY.PA), the MedImmune unit of AstraZeneca (AZN.L), GlaxoSmithKline (GSK.L) and Novartis (NOVN.VX) also produce H1N1 vaccines.

Other flu treatments are expected to bolster the bottom line of drugmakers, as well.

Roche ROG.VX on Thursday reported stronger-than-expected third-quarter sales of its antiviral drug Tamiflu and raised its sales forecast on the medicine for the full year.

The robust Tamiflu sales reported by Roche also signal a small windfall ahead for Gilead Sciences Inc (GILD.O), which collects a healthy royalty on sales of the medicine.

Robert W Baird analyst Thomas Russo forecast in a research note that Tamiflu sales would add 8 cents a share to Gilead's fourth-quarter earnings and another 6 cents per share to its first-quarter 2010 results.

More significantly, Russo said Roche commentary suggests that "a higher level of sales maybe sustainable over the intermediate term at least," a longer period than investors are generally accustomed to. He noted that several governments that stockpile Tamiflu as a hedge against pandemic flu outbreaks are now looking to reorder the drug as some of their current inventories approach a seven-year expiration date.

Swine Flu Shots Revive a Debate about Vaccines

The New York Times, 15 October 2009
https://www.nytimes.com/2009/10/16/health/16vaccine.html

People who do not believe in vaccinating children have never had much sway over Leslie Wygant Arndt. She has studied the vaccine debate, she said, and came out in favor of having her 10-month-old daughter inoculated against childhood diseases. But there is something different about the vaccine for the H1N1 flu, she said.

"I have looked at the people who are against it, and I find myself taking their side," said Ms. Wygant Arndt, who lives in Portland, Ore. "But then again I go back and forth on this every day. It's an emotional topic."

Anti-vaccinators, as they are often referred to by scientists and doctors, have toiled for years on the margins of medicine. But an assemblage of factors around the swine flu vaccine – including confusion over how it was made, widespread speculation about whether it might be more dangerous than the virus itself, and complaints among some health care workers in New York about a requirement that they be vaccinated – is giving the anti-vaccine movement a fresh airing, according to health experts.

"Nationally right now there is a tremendous amount of attention on this vaccine," said Dr. **Thomas Farley**, the New York City health commissioner. That focus has given vaccine opponents "an opportunity to speak out publicly and get their message amplified that they didn't have at other times," he said.

Barbara Loe Fisher, president of the National Vaccine Information Center, an advocacy group that questions the safety of vaccines, said the swine flu has "breathed new life" into the cause. "People who have never asked questions before about vaccines are looking at this one," Ms. Fisher said.

The increased interest is frustrating to health officials, who are struggling to persuade an already wary public to line up for shots and prevent the spread of the pandemic. According to a CBS News poll conducted last week, only 46 percent said they were likely to get the vaccine. The nationwide poll, which has a margin of sampling error of plus or minus three percentage points, found that while 6 in 10 parents were likely to have their children vaccinated, less than half said they were "very likely to."

"I wonder if the people disseminating this false information about this vaccine realize that what they are doing could result in some people losing their lives," said Dr. Jonathan E. Fielding, the director of the Department of Public Health for Los Angeles County. The comments of vaccine dissenters, which he said "politically come from the left and the right," were frequently "not just counterproductive," he said, "but downright disgraceful."

Web sites, Twitter feeds, talk radio and even elevator chatter are awash with skeptics criticizing the vaccine, largely with no factual or scientific basis. The most common complaint is that the vaccine has been newly formed and quickly distributed without the benefit of clinical trials; in fact, the swine

flu vaccine was made using the same techniques as seasonal flu shots over the last two decades, and a small number of clinical trials were conducted this year to determine the adequate dose.

There are also claims that the vaccine contains adjuvants – sometimes added to make vaccines more effective – although they have not been used in this one. In addition, there is fear that the vaccine could lead to Guillain-Barré syndrome, as was suspected the last time a swine flu vaccine was distributed, in 1976; flu vaccines are now much purer than they were, minimizing the risk, and Guillain-Barré is far rarer.

In measuring the risk of the vaccine, there is general consensus among doctors that serious adverse reactions are rare and that pregnant women and young people, in particular, are better off with the vaccine than without it. While most people who get H1N1 experience mild symptoms, a recent New England Journal of Medicine study showed that among Americans hospitalized with swine flu last spring, one in four ended up in intensive care and 7 percent of them died.

The illness, unlike other flu strains, has been particularly tough on children and young adults and appears to have a disproportionately high fatality rate in pregnant women.

Health care officials are concerned that some groups, especially pregnant women, are potentially swayed by the large-scale efforts of vaccine opponents.

"One of the things they are focusing on now is immunization and pregnancy," said Saad B. Omer, assistant professor of global health at Rollins School of Public Health at Emory University, "and their perceptions of the vaccine in use of pregnant women. It is not a benign perception in this case, and could have serious impacts, because pregnant women have high risk of complication if they get the swine flu."

The anti-vaccine movement, largely comprising activists and a handful of doctors and researchers who connect a variety of health problems – particularly autism spectrum disorders – to vaccines, has failed to find large-scale traction in the United States, where more than 90 percent of children are vaccinated.

But at a conference this month of National Vaccine Information Center, Ms. Fisher said, there were 675 people, more than double the number at the group's last conference, and half said they were there to discuss swine flu. Unlike most people associated with the center, who have longstanding objections to vaccines or have a connection to the issue because of an autistic child, the newcomers were not traditional skeptics, Ms. Fisher said. "They came not knowing much," she said, "and left galvanized."

Further, vitamin vendors – who in some cases operate blogs, with postings by people who claim to be doctors finding fault with vaccines – are reporting an increase in sales related to swine flu. Michael Angelo, chief research and information officer for eVitamins.com, said sales in September for flu-related products had tripled from last September. The company, he said, has sold 17,565 vitamins that it says protects against the H1N1 virus.

Some anti-vaccine groups are also highly organized and quick to respond to openings to promote their message. For instance, this week, an 8-year-old boy from Long Island died roughly a week after receiving a seasonal flu vaccine, though officials from the New York State Department of Health denied a connection.

Almost instantly, on a memorial page on Newsday's Web site for the boy, Sean Weisse, a message from an anti-vaccine advocacy group appeared: "We are so sorry to hear about Sean. My understanding, and forgive me if I'm wrong, is that this was a vaccine-related injury. If so, we would like to help you. Best regards, Stan Kurtz, Generation Rescue, Jim Carrey and Jenny McCarthy's Organization."

Swine flu: Chief medical officer admits concern at spike in critical cases

The Guardian, 15 October 2009, 21.35 BST
https://www.theguardian.com/world/2009/oct/15/swine-flu-critical-cases-rise

More than 100 people have died from swine flu and intensive care beds are filling up with victims, the government's chief medical officer revealed today.

A sharp rise in the proportion of hospital patients needing critical care is a matter "of some concern", Sir Liam Donaldson admitted as he unveiled the national vaccination programme due to start next week.

High-risk patients and frontline health workers in hospitals will be the first to be inoculated from 21 October. More than 4m doses of Pandemrix will be delivered to GP surgeries the following week so that patients in priority groups can be given protective injections.

A national postal strike could disrupt the process severely, Donaldson warned, saying it could prevent doctors from sending out letters to vulnerable patients to invite them in for vaccination.

"We are worried about the postal strike," the chief medical officer said. "GPs need to send letters out to patients. [A strike] would be an extremely unwelcome piece of timing. We need to get people into GPs' surgeries to give them this life-saving vaccine."

There were about 27,000 new cases of swine flu last week, an increase on the 18,000 new cases in the previous week. There have now been 106 deaths in the UK connected to the virus: 83 in England, 15 in Scotland, four in Wales and four in Northern Ireland.

Two of the latest people to die were pregnant women, a group emerging as a particularly at risk in the outbreak.

David Salisbury, director of immunisation at the Department of Health, dismissed fears that the "adjuvants" – material added to the vaccine to boost the body's immune response – would harm pregnant women.

The Pandemrix vaccine, he said, would provide virtually immediate immunity and guard against a broader spectrum of flu viruses.

Freshly issued advice from the World Health Organisation today confirmed that "the GSK [Pandemrix] vaccine has been licensed for use in pregnant women in Europe as of September 2009". Salisbury promised, however, to review the data.

There are 364 people in British hospitals with H1N1 swine flu, of whom 74 are in intensive care. "This is the highest proportion [of hospital patients] needing critical care since this all began," Donaldson said. "Most of the time it's been around 12% or 13%. Now it's up to 20%.

"We are seeing more serious cases than before but no sign of any change in the virus. This is giving me some concern. There's a school of thought that when a flu virus is operating in the summer it's milder than when it's operating in the flu season without a change in the virus.

"We don't understand why. We are doing a more detailed study of hospital patients," Donaldson said.

The Ministry of Defence announced that 15,000 doses of the vaccine would be delivered to the 9,000 UK troops serving in Afghanistan.

"We can't afford to have soldiers off with flu if we can prevent that," said an MoD spokesman.

No cases have yet been reported among servicemen there. The Department of Health is reviewing whether any other groups should be deemed high-risk categories and given early vaccinations against swine flu.

Among the latest deaths was a pregnant teenager from southern Scotland, whose unborn child also died. The 17-year-old was being treated in a hospital in the Borders region.

Her death was the latest in a series in Scotland: four deaths were reported in one 48-hour period earlier this week.

Health officials in Wales said that a pregnant woman, aged 21, from Monmouthshire, died in intensive care after a planned caesarean section. Three deaths were reported in Wales in 24 hours. Six pregnant women have now died from the virus in the UK.

Another pregnant woman who contracted the virus, Sharon Pentleton, has given birth to a son at Crosshouse hospital in Kilmarnock. In July, when she was six months pregnant, she was airlifted from Ayrshire for highly specialised treatment in Sweden which oxygenated her blood outside her body.

Nicola Sturgeon, the Scottish health secretary, yesterday urged pregnant women to take the new H1N1 vaccine to ensure they had "maximum protection" for themselves and their babies.

Vaccination schedule

21 October 415,000 doses of the vaccine Pandremix will be given to high-risk patients in hospitals and to frontline health workers.

Week beginning 26 October 4.4 million doses of Pandremix to be delivered to GPs. Doctors will inoculate patients in priority groups – such as those with compromised immune systems and pregnant women.

At the same time 236,500 doses of Pandremix and 49,200 doses of another vaccine, Celvapan, will be sent to NHS primary care trusts.

The World Health Organisation has backed the use of Pandremix for pregnant women despite claims ingredients have not been sufficiently tested on expectant mothers-to-be

Grippe A(H1N1): l'étrange alliance de l'extrême gauche et de l'extrême droite américaines

Slate, 16 Octobre 2009
https://www.slate.fr/story/11779/grippe-ah1n1-letrange-alliance-de-lextreme-gauche-et-de-lextreme-droite

La grippe A pourrait bien avoir un effet secondaire imprévu: une étrange forme d'unité politique. Dernier exemple en date: aux Etats-Unis, l'extrême gauche et l'extrême droite – qui sont rarement sur la même ligne – s'accordent aujourd'hui sur un point. Elles ne veulent pas du vaccin anti-grippe.

Les opposants se déchaînent dans les médias

Du côté de la droite anti-gouvernementale, on condamne l'interventionnisme (forcément injustifié...) de l'administration Obama. Rush Limbaugh, animateur de radio conservateur et opposant déclaré d'Obama, a récemment fait les gros titres en annonçant qu'il ne se ferait pas vacciner. «Allez vous faire voir, Mme Sebelius!», a-t-il déclaré pendant son émission de radio - il faisait référence à Kathleen Sebelius, la secrétaire à la santé et aux services sociaux. «C'est précisément parce que vous voulez que je me fasse vacciner que je n'en ferai rien.» Quant à Glenn Beck, commentateur sur Fox News lui aussi conservateur, il a refusé de dire s'il se ferait vacciner ou non. Reste qu'il n'a pas vraiment fait mystère de son opinion personnelle : il a laissé entendre que le vaccin pourrait s'avérer «mortel», a brandi le spectre de la vaccination obligatoire (elle ne l'est pas), et a déclaré que le gouvernement n'avait pas à lui dire «quand et comment se soigner».

A gauche, les porte-étendards de la résistance sont des médecins célèbres, des avocats et des célébrités hollywoodiennes; ils rejettent les vaccins en général, et le vaccin contre la grippe A(H1N1) en particulier. Dans un article paru dans le Huffington Post en septembre dernier, le docteur Frank Lipman a mis en garde les lecteurs de ce site d'information contre une vaccination selon lui inutile, le virus étant bénin et l'efficacité du vaccin n'étant pas encore prouvée. Plus tôt cette année, l'acteur Jim Carrey avait déclaré (sur le même site) que les vaccins pouvaient rendre autiste, une théorie plusieurs fois avancée et dont il a été maintes fois démontré qu'elle n'était pas scientifiquement fondée. Robert F. Kennedy Junior avait peu ou prou tenu les mêmes propos dans un célèbre article (tout autant décrié) de 2005, paru dans Rolling Stone et Salon. Les opposants à la vaccination ne sont pas tous de gauche, mais les baisses des taux de vaccination sont dues en grande partie aux refus de familles aisées vivants pour la plupart en Californie (ou dans d'autres Etats du même type).

Aujourd'hui, alors que le gouvernement américain s'apprête à expédier 250 millions de doses de vaccin contre la grippe A(H1N1) dans les cinquante Etats, les deux extrêmes font cause commune. Leurs opinions politiques divergent, mais d'une certaine manière, ces hommes et ces femmes – qu'ils s'en prennent à la médecine moderne ou au gouvernement – per oivent le monde de la même manière: avec méfiance. Il arrive même qu'ils tiennent le même discours: Glenn Beck a par exemple déclaré qu'on «ne pouvait pas savoir si le vaccin entrainerait l'apparition de troubles neurologiques, comme dans les années 1970», un argument souvent utilisé par les opposants à la vaccination. (Les théories selon lesquelles le vaccin contre la grippe de 1976 avait été à l'origine de l'apparition du

syndrome de Guillain-Barré chez certaines personnes vaccinées n'ont jamais été scientifiquement démontrées). Et de leur côté, les anti-piqûres n'ont pas vraiment confiance en leur gouvernement: le docteur Lipman a rappelé que le secrétariat à la santé et aux service sociaux américain avait d'ores et déjà accordé l'immunité judiciaire aux groupes pharmaceutiques qui produisent les vaccins..

Le gouvernement fait campagne pour mettre fin aux fantasmes

Le secrétariat à la Santé a créé une page internet «Info et Intox» pour mettre un terme aux soupçons et à l'inquiétude grandissante de certaines personnes. Symptôme le plus exemplaire: beaucoup d'Américains pensent encore que la vaccination est obligatoire. «La campagne de vaccination du gouvernement fédéral contre la grippe A(H1N1) est FACULTATIVE», rappelle le site, qui assure par ailleurs que la pétition en ligne affirmant le contraire est «tout simplement mensongère». Plus bas sur la page, le secrétariat répond aux citoyens qui pensent que les vaccins peuvent provoquer des crises cardiaques, des fausses couches, ou le syndrome de Guillain-Barré: «ces problèmes ne touchent pas plus les personnes vaccinées que les personnes non-vaccinées».

Tous les fantasmes associés au vaccin ne sont pas issus d'un délire «de gauche» ou d'un délire «de droite»; certains sont tout simplement... délirants. Selon plusieurs sites Web, la grippe A(H1N1) aurait été élaborée par le gouvernement; elle aurait notamment pour objectif d'implanter des micro-puces dans l'organisme des citoyens, et servirait à détecter les «bio-menaces». Il existe au moins un site avançant la théorie selon laquelle le vaccin contiendrait un «Codat à la Santé ne s'est pas encore attaqué à cette histoire-là...

L'administration Obama sait y faire pour ce qui est de pourfendre les rumeurs. En 2008, les responsables de sa campagne ont créé un site Web, «Fight the Smears» (Combattre la diffamation), pour contrer les calomnies affirmant que le candidat démocrate n'était pas né en Amérique, ou encore que Michelle Obama avait été surprise en train de prononcer le mot «whitey» (insulte raciale visant les blancs) sur une vidéo. Mais il est plus difficile de combattre une rumeur portant sur les vaccins. Pendant la campagne présidentielle, la plupart des propos diffamatoires venaient de la droite; aujourd'hui, le secrétariat à la santé doit faire face à une série d'assauts lancés depuis les deux extrêmes du spectre politique. Il se voit donc contraint de marcher sur des œufs: corriger les mensonges et les approximations sans pour autant offenser ses alliés potentiels. Ce qui n'est pas simple, étant donné la forte teneur émotionnelle du sujet. On comprend donc mieux pourquoi les fonctionnaires du secrétariat prennent le temps de répondre avec sérieux et professionnalisme à des questions frôlant l'absurde (« Peut-on attraper la grippe A(H1N1) en mangeant du porc?»).

Ce vaccin n'est pas le premier à générer une psychose

Comment expliquer cette étrange alliance des extrêmes? En réalité, la résistance anti-vaccin a toujours été une lutte bipartisane. La dernière psychose en la matière remonte à 1976; le président était alors républicain. Pendant les trois mandats Bush (père et fils), plusieurs troupes stationnées dans le Golf Persique ont refusé de se faire vacciner contre l'anthrax.

La trypanophobie (peur morbide des vaccins) est une angoisse assez répandue. Une récente étude réalisée par la Harvard School of Public Health a noté que seuls 40% des adultes disaient être certains de vouloir se faire vacciner. Lorsqu'on leur a demandé pourquoi ils refusaient de faire vacciner leurs enfants, la troisième raison invoquée par les parents était: «Les représentants de la santé publique ne sont pas à même de nous informer quant aux dangers potentiels des vaccins.» Les jeunes, catégorie pourtant assez vulnérable au virus, ne sont pas beaucoup plus raisonnables. Vincent Racaniello, professeur de microbiologie à l'Université de Columbia, a récemment demandé à 50 de ses étudiants qui parmi eux comptait se faire vacciner. Pas une seule main ne s'est levée. «C'était justement pendant un cours sur la grippe, se rappelle-t-il. J'imagine que j'ai mal fait mon boulot.»

Il faut bien l'admettre: il n'y a rien de plus universel que la peur des piqûres. «Je pense que certaines personne fonctionnent comme ça, tout simplement, nous dit Gregory Poland, de la Mayo Clinic. Ils fondent leur jugement sur leurs émotions ou sur des anecdotes - ce qu'ils lisent à l'Université ou sur Google - plutôt que sur les points de vue étayés par des faits et des données». Au 19ème siècle, les gens pensaient que le vaccin contre la «variole des vaches» ferait pousser des appendices bovins sur leurs bras. Au début de la première guerre mondiale, on s'est amplement moqué du grand médecin canadien William Osler lorsqu'il préconisa une vaccination des troupes britanniques contre la fièvre typhoïde. Le gouvernement français a cessé de proposer la vaccination contre l'hépatite B dans les écoles en 1998 ; on enquêtait alors sur de possibles liens pouvant exister entre cette vaccination et la sclérose en plaques (des recherches ultérieures n'ont décelé aucun lien de cause à effet).

Reste que le climat politique actuel est un véritable bouillon de culture pour la psychose collective née du A(H1N1). D'une part, le débat nourri par la réforme du système de santé a déjà mis dans la tête de certaines personnes que le gouvernement pourrait se servir du monde médical pour mettre à mal le peuple américain (la sévérité des accusations varie, entre «imprudence bien intentionnée» et «conspiration visant à dominer le monde»). D'autre part, dans l'Amérique post-Katrina, il serait inexcusable de ne pas se tenir prêt face à un désastre potentiel. Dans ce genre de situation, un politicien préfère en faire trop plutôt que pas assez.

Mais Obama n'est pas n'importe quel politicien: il lui faut faire avec Internet (qui déforme les informations et amplifie les angoisses) et avec la vague paranoïa qu'il semble inspirer à une fraction de la population. Lors d'une récente émission de radio animée par Glenn Beck, un auditeur s'est ouvert du motif véritable de sa phobie: «Si on était il y a cinq ans, j'aurais sans doute dit d'accord, pas de problème, je vais [me faire vacciner]». Peut-être que la véritable raison poussant les membres des deux extrêmes à ne pas se vacciner est ailleurs; peut-être qu'elle est à la fois plus simple et plus élégante. Elle tient en deux mots: sélection naturelle.

Swine flu vaccine ordered for all British troops serving in Afghanistan

The Times, 16 October 2009, 1.01 am BST
https://www.thetimes.co.uk/article/swine-flu-vaccine-ordered-for-all-british-troops-serving-in-afghanistan-p7chpnsvflq

The Ministry of Defence said it will obtain 15,000 doses – enough for the 9,000 servicemen and women deployed and the 500 extra troops announced on Wednesday.

Support staff, such as RAF crews who fly troops to and from Afghanistan, will also be vaccinated.

An MoD spokeswoman said the move was to avoid putting strain on combat medics, as well as to protect troops against infection. "We can't afford to have soldiers off with flu if we can prevent that," she said.

The Department of Health will include those deployed to Afghanistan in their priority group for vaccination, the MoD said.

The military programme will begin after the vaccine has been given to ...

Swine flu vaccination to start, UK deaths pass 100

Reuters, 16 October 2009, 1:50 AM GMT+8
https://www.reuters.com/article/uk-flu-britain-idUKTRE59E3MA20091015/

London (Reuters) **-** Britain, which has seen more than 100 deaths linked to the H1N1 swine flu virus, will start a nationwide vaccination programme next week, its chief medical officer said on Thursday.

The UK is the latest to begin mass immunisation ahead of a feared second wave of infections. Similar programmes are already underway in the United States, China and Australia.

A total of 415,000 doses of GlaxoSmithKline's
"The programme will be rolling from next week," medical chief Liam Donaldson told reporters.
From the week beginning October 26, 4.4 million doses of Pandemrix and 49,000 doses of Baxter's Celvapan will be delivered to family doctors for patients in priority groups.

David Salisbury, director of immunisation, said Britain was expecting more vaccines to come from Baxter but added: "We are much less confident of their delivery schedule than we are of GSK's" due to yield problems.

The government has previously said the first to be immunised would be about 5 million people aged over six months in current seasonal flu risk groups, all pregnant women, contacts of people with compromised immune systems, and front-line health and social care workers. In total, around 11 million people are in line for the first phase of vaccination.

All those over 10 years of age receiving Glaxo's vaccine will get a single shot, but children from six months to 9 years will receive two doses, as will everybody receiving Celvapan.

Baxter's Celvapan, which is produced by cell culture, will be mainly reserved for people with egg allergies.

Donaldson also said a further 15,000 doses of vaccine would be offered to British troops serving in Afghanistan.

Responding to concerns about giving swine flu shots to pregnant women, officials said they were confident the vaccines were safe and offered a valuable protection against a potentially dangerous disease. – "I do not want to see pregnant women dying of a preventable disease – that's the bottom line," Donaldson said.
Health officials said that in the past week there were an estimated 27,000 new cases of H1N1 flu, up from around 18,000 in the previous week, and the total number of deaths rose past 100.

There have now been 83 deaths from swine flu in England, 15 in Scotland, four in Wales and four in Northern Ireland.

Donaldson said he was "concerned about the relatively high number of patients" who were becoming seriously ill, adding that the proportion of hospitalised patients in critical care was at its highest level in Britain since the outbreak began. "For most of the time it's been about 12 to 13 percent, but now it's up to 20 percent -- suggesting we are seeing more serious cases," he said. "There is no sign of any change in the virus, but this is giving me some concern."

COUNCIL *on* FOREIGN RELATIONS

Pandemic Influenza: Science, Economics, and Foreign Policy
Session I

Council on Foreign Relations, 16 October 2009
https://www.cfr.org/event/pandemic-influenza-science-economics-and-foreign-policy

Laurie Garrett: Good morning, and good morning to all of you on the Internet. My name is Laurie Garrett, and you are here in the Council on Foreign Relations in New York on a grim, wet, chilly day. Thanks to all of you who managed to forge through the nasty weather. And I expect that we'll have stragglers coming in as a result of the weather problems.

I am the senior fellow for Global Health here at the Council on Foreign Relations, and I welcome everybody who is both here and in cyberspace with us.

In a few moments my colleague, Jon Cohen, will tell those of you out in the cyber world how you can actively participate all day today via Twitter. Jon is the outstanding, infamous, notorious, famous science correspondent for Science Magazine, which is our co-sponsor today. It's a first for the Council on Foreign Relations. We embrace it wholeheartedly and hope it will be the beginning of many more to come, for this symposium entitled "Pandemic Influenza: Science, Economics, and Foreign Policy."

On August 24th, the President's Council of Advisers on Science and Technology, some of whom are with us today, so-called PCAST, issued a remarkable analysis of what's in store with the H1N1 virus, the so-called swine flu, and the likely pandemic impact this fall on the United States of America.

The PCAST offered a scenario -- not a prediction, let me say -- a scenario that suggested the virus would indeed return, having already been here in the spring, for a second wave, and that we would see it appear sometime in September and be peaking right about today in the United States, and that sometime, by the end of the year, roughly half of the American population would have had H1N1 influenza.

The PCAST warned that this H1N1, despite being a not terribly dangerous virus in and of itself on a scale of influenza dangers, would overwhelm many of our hospitals and pose a great burden to our intensive-care-unit capacities across the country.

After circulating in the southern hemisphere for the last three or four months, H1N1 did indeed return as forecast, or shall we say scenario'd, by PCAST and has now been back in most of the United States for at least two weeks. It is indeed surging very rapidly around the country.

On Tuesday, Dr. Ann Schuchat from the Centers for Disease Control opened a press briefing with these remarks: "Unfortunately, we're seeing more illnesses, more hospitalizations and more deaths from it. Flu is widespread in 37 states. That's up from 27 states just last week. Unfortunately, 19 more pediatric deaths from influenza got reported to us this past week. We're now up to 76 children having died from the 2009 H1N1 virus." She means in the United States.

To put that in context, in the past three years the total pediatric influenza deaths ranged from 46 to 88. We've had 76 children dying from the 2009 H1N1 virus, and it's only the beginning of October.

There's a great deal of uncertainty about this flu pandemic. One thing is certain: It is a worldwide event, and it is occurring in the dawn of our age of globalization.

With us today is a stellar group of scientists -- some of them PCAST members, as I said -- analysts, journalists, and, as usual at the Council on Foreign Relations, a highly diverse and intelligent audience.

Before we jump into the subject at hand, a few quick bits of housekeeping and a set-up for what we're going to experience today. We have three panels with two short breaks. And because this is live on the Web, we're going to ask that the audience that's physically here in New York please clear out quickly during breaks and come back quickly during breaks so that we stick to our time schedule absolutely.

In addition, a couple of other things. Because we are live on the Internet, absolutely no wireless devices can be on in this room. It's not just we don't want them to ring; we don't want them to interfere. So PDAs, cell phones, laptops, whatever they are, please turn them off.

We welcome that webcast audience. And as I said, Jon is going to tell you how you can twitter. And because this is the first big event co-sponsored with Science Magazine, we really want to thank and welcome all the folks from AAAS and Science for their participation and the tremendous help we got in organizing today's event.

...

Cohen: I think there's a lot of curiosity about why young people in particular and pregnant women are seeing a lot more severe disease. Flu typically causes the most mortality in the elderly. That's not happening with this. Do you have any ideas as to why the younger population is being hit so hard, and pregnant women? Is it biological? Is there an epidemiologic explanation?

Monto: Well, I'll try to add a few things from the historic record, which I'm sure Lone can further add to, and that is, in 1918 -- and this is a whole lot different from 1918; I think Lone and I can have a conversation about that -- but in 1918 it was very clear that pregnant women were at particular risk. There are some contemporaneous curves looking at puerperal mortality, deaths in pregnant women. And there is a big spike in 1918 when this was going down on a year-to-year basis.

Women were heavily infected and quite ill, and they often lost their babies if they were in late stages of pregnancy. So this is not particularly unique. It's a little more questionable in some of the later pandemics. And because of this, we in the U.S. -- and we're one of the few countries that has this recommendation - recommends the use of seasonal vaccine in pregnant women, because we know that this is a particularly vulnerable population.

Why in this pandemic is it so much more extreme in terms of what's going on? It's hard to say. We can speculate about that. We can speculate about obesity as an -- whether it's an independent risk factor. But I think a lot of what is going on is really based on the fact that there has been past experience with this virus. And we see this in terms of the way the vaccine is working; the fact that we only need, for most of the population, one inoculation with this vaccine, which means there is some degree of relative immunity in the population.

And there's been a debate about whether, to have a pandemic, a real pandemic, you need to have a totally novel virus. And one of the reasons we've seen partial sparing in older individuals in past pandemics is these were not totally novel viruses. There was some degree of antibody in the population.

...

Palese: Maybe let me start this one out. So even though I mentioned that this 2009 novel influenza virus is really like a regular seasonal influenza virus in many of its characteristics, that doesn't mean that I underestimate influenza. Regular seasonal influenza is a very bad disease. And we all know that in the U.S. alone we have about 30,000 deaths and we have about 200,000 hospitalizations every year.

So regular flu is a very serious disease and therefore we should really use all the tools we have to combat and to fight the regular flu, and that includes vaccination. And by the same token I think it is really compelling that we should use the vaccines which are being produced and being distributed right now against the 2009 virus. So, by not taking the vaccine, by underestimating this disease, I think we are not helping us.

Cohen: Any dissent?

Simonsen: No. I mean, it's very clear that vaccination is the best defense we have against pandemic influenza. In fact, when you have a pandemic unfolding and really high transmission rates, it becomes very hard to mitigate with any other strategy than that.

So, from a personal point of view, I have the advantage of natural immunity at this point, I'm pretty sure.

...

Simonsen: Well, I think this is very interesting because, I mean, especially for the health-care worker example. I mean, there are many, many good reasons why health care workers should be considering immunization for their own safety but also to protect and, first, do no harm to the patients that they are treating. Having said that, does it work to mandate?

I think what would work better would be to say that there was a shortage and people tend to buy more of something that's in demand. (Laughter.) We saw that – there was one season where, really, people lined up all night to get a flu shot.

https://web.archive.org/web/20091024040003/http://www.theflucase.com/index.php?option=com_content&view=article&id=1165:us-governments-64-billion-swine-flu-jab-program-will-put-public-health-sector-under-unprecedented-strain-experts-say&catid=1:latest-news&Itemid=64&lang=en

The U.S. government's $6.4 billion (3.9 billion pounds) swine flu vaccination program is likely to put the American public health sector under unprecedented strain and expose serious shortcomings, experts say.

As the first mass U.S. immunization program in a generation ramps up to deliver tens of millions of doses each week, public health experts disagree about how well the country's network of state and local health departments might perform.

But many say the sector never received the money it needed for large-scale immunizations despite years of planning for pandemics after the re-emergence of bird flu in Hong Kong and South Korea in 2003.

"The worst-case scenario is that there is vaccine in a particular state or locale but that state or locale hasn't sufficiently planned to distribute it," said Leonard Marcus of the Harvard School of Public Health.

Marcus, who studied the 2005 Hurricane Katrina disaster, said the H1N1 immunization program could encounter similar breakdowns in leadership and coordination wherever local public health systems are underfunded or poorly managed.

"Some bureaucrat is going to say he doesn't have authority or needs a signature and it's going to stop the system from moving. That could very well cause panic," he said in a telephone interview.

Experts give the Obama administration high marks for creating a program capable of procuring 250 million doses and distributing them to 90,000 sites nationwide so that every American who wants the vaccine can get it.

The government has ordered vaccine from five companies -- Sanofi-Aventis , CSL , Novartis , GlaxoSmithKline and the AstraZeneca unit MedImmune.

"Rusty Faucet"

Bob Hutchens, a vaccine distribution expert with consulting firm Booz & Co, expects overall success.

"There will be some long lines, there may need to be some late hours and people may not be able to get it the day they want it," he said. "But if we approach this soundly and rationally, I suspect we'll be just fine."

But with the United States struggling to recover from an economic recession, staffing could be an issue.

Local health departments eliminated 8,000 positions in the first half of this year, after 7,000 job cuts in 2008, according to the National Association of County and City Health Officials. Another 12,000 employees have been subjected to reduced hours or mandatory furloughs this year.

The Association of State and Territorial Health Officials says three-quarters of states have cut public health funding this year, while 61 percent expect smaller budgets in 2010. Seven states have cut back specifically on immunization.

Layoffs have targeted people needed for the H1N1 program -- nurses, nurse's aides and switchboard operators and receptionists who would help field public queries.
"The problem is that there's a big rusty faucet at the end of the vaccine pipeline," said the University of Minnesota's Michael Osterholm, who warns public fears could flare quickly if H1N1 overwhelms hospitals and their intensive care units.

A poll by the American College of Emergency Physicians says almost 90 percent of emergency room doctors worry hospitals could have a hard time responding to a surge in H1N1 flu.
"Public health is the life raft," Osterholm said. "But are they big enough to get everybody on board and how will they navigate those rough waters?"

Experts were careful not to criticise the calibre of public health staff, widely respected for their energy and devotion.

But they said meagre resources, combined with the scale and speed of the national immunization program, will bring unprecedented strains.

Frayed Nerves

That could mean bad news for 46 million Americans with no health insurance, who could flood public health offices where vaccinations will be free.
"It could overload some systems in terms of staffing and frayed nerves," Hutchens said.

The Obama administration has sought to smooth the program's path by giving health departments and hospitals $1.4 billion to help plan and implement the vaccination effort, including the hiring of additional staff and contractors.

"We can't do this ourselves," said Fran Phillips, deputy secretary of Maryland's public health services, whose staff has assembled 3,000 private vaccinators to supplement two-dozen local public health departments. Maryland has received $24 million in federal grants to help with the effort.

Preparations appear to be less uniform in states like Michigan, where much of the authority rests with local health departments. Michigan received $34 million in federal money.

"They're really in the process right now of utilizing the funds, hiring folks or contracting with vaccinators," said Dr. Eden Wells of the Michigan Department of Community Health.

"It's too early to make a judgement about whether the (federal) money is enough."

SPIEGEL Wissenschaft

Länder bestellen Impfstoffe ohne Wirkverstärker nach

Spiegel, 16 Oktobre 2009, 17.53 Uhr
https://www.spiegel.de/wissenschaft/medizin/h1n1-impfaktion-laender-bestellen-impfstoffe-ohne-wirkverstaerker-nach-a-655664.html

Erfurt - Die Bundeswehr bekommt Schweinegrippe-Impfstoffe ohne Wirkverstärker, weil diese verträglicher seien - als diese Nachricht an die Öffentlichkeit gelangte, entbrannte eine erneute Diskussion um die Nebenwirkungen der Zusatzstoffe. Mit oder ohne Adjuvans? Das fragen sich derzeit viele.

Um die Debatte zu entschärfen, haben die Bundesländer jetzt Konsequenzen gezogen und bestellen Impfstoffe ohne die umstrittenen Wirkverstärker nach. Thomas Schulz, Sprecher des Thüringer Gesundheitsministeriums, sagte am Freitag, es liefen derzeit Gespräche mit verschiedenen Herstellern über einen begrenzten, bedarfsgerechten Nachkauf des Impfstoffs.

Hintergrund seien Bedenken von Medizinern, dass der bisher bestellte Impfstoff mit Wirkstoffverstärkern für Schwangere möglicherweise weniger geeignet sei. Auch Kinderärzte hatten in Deutschland für ihre jungen Patienten einen möglichst verträglichen Impfstoff gegen die H1N1-Erreger gefordert - ohne Zusätze, so wie er auch in den USA für Kinder zur Verfügung gestellt wird. Den Kritikern zufolge können die Dosen mit Wirkverstärkern zu gesteigerten Impfreaktionen wie Kopfschmerzen oder Fieber führen. Bundesgesundheitsministerin Ulla Schmidt (SPD) betonte derweil, dass auch der Impfstoff mit Wirkstoffverstärkern sicher sei.

Impfkampagne beginnt am 26. Oktober

Das neue Präparat werde voraussichtlich bis Mitte oder Ende November zur Verfügung stehen, sagte Schulz. Die Impfkampagne gegen die Schweinegrippe soll am 26. Oktober beginnen. Einige Europäische Länder haben mit den Masseimpfungen bereits begonnen, in Großbritannien soll die Kampagne kommende Woche starten. Die Bundesländer gehen nach Angaben des Thüringer Ministeriums davon aus, dass etwa 200.000 Dosen des alternativen Impfstoffs benötigt werden. In dieser Größenordnung bewege sich die geschätzte Zahl Schwangerer, die sich impfen lassen wollten. Vom Impfstoff mit Adjuvantien haben die Länder bisher 50 Millionen Dosen bestellt.

Bisher wird neben Schwangeren und Kindern auch chronisch Kranken sowie medizinischem Personal zur vorsorglichen Impfung geraten. Geschätzt wird, dass sich insgesamt etwa jeder fünfte Bundesbürger gegen die Schweinegrippe impfen lassen möchte.

Nach Angaben des Pharmakonzerns GlaxoSmithKline (GSK) soll in der kommenden Woche mit der Auslieferung von Impfstoffen begonnen werden. Die Firma produziert Pandemrix, der in Deutschland zugelassen ist. Mit dem zusatzfreien Impfstoff stehe den Ärzten nun eine Alternative zur Verfügung. "Sie können nach genauer Risikoabwägung entscheiden, welchen Impfstoff sie ihren Patienten geben", sagte Schulz. Seinen Angaben nach handelt es sich bei dem Vakzin ohne Adjuvantien aber nicht um das Präparat, das die Bundeswehr für ihre Soldaten geordert hatte. Dieses sei für Schwangere nicht geeignet, so Schulz.

Die Impfstoff-Diskussionen hätten für Irritationen gesorgt, räumte der Ministeriumssprecher ein. Jetzt rief er die Bevölkerung dazu auf, sich nicht verunsichern zu lassen. Die Landesärztekammer glaubt aber, dass die bevorstehende Impfaktion auch von praktizierenden Medizinern in Thüringen unterschiedlich beurteilt wird. Die Meinungen seien geteilt, sagte eine Sprecherin. "Das ist auch kein Wunder, wenn sich sogar die Virologen als Experten unterschiedlich positionieren." Die meisten Mediziner unterstützten die Aktion. Dafür spreche auch die erklärte Bereitschaft von 1400 niedergelassenen Ärzten, die Impfung vorzunehmen. Verschiedene niedergelassene Ärzte raten ihren Patienten aber auch von der Impfung ab.

Und wie steht es mit der Bevölkerung? Laut einer Umfrage von Infratest dimap bleiben die Deutschen skeptisch. Mehr als die Hälfte der Bundesbürger hält eine Impfung gegen das H1N1-Virus nicht für nötig. 39 Prozent würden sich auf keinen Fall impfen lassen; jeder Vierte würde wahrscheinlich nicht zur Impfung gehen.

The Virginian-Pilot

Swine flu vaccine delivery into Va. delayed

The Virginian-Pilot, 16 October 2009, 12:00 a.m.
https://www.pilotonline.com/2009/10/16/swine-flu-vaccine-delivery-into-va-delayed/

A manufacturer delay will slow the flow of swine flu vaccine into Virginia in coming weeks, but health care providers will continue to vaccinate high-risk people with what's available.

"The key phrase here at the health department is 'flexibility and patience,'" said State Health Commissioner Karen Remley, who gave an update on vaccine distribution at a Friday news conference.

About 265,000 doses have been shipped to Virginia health care providers, including health departments, doctors and hospitals. The state started receiving H1N1 vaccine during the first week of October. Health care providers and emergency medical services workers were the first to be vaccinated.

People in priority groups began being vaccinated this week, and school-based clinics for children start next week in Hampton Roads.

Friday, however, the U.S. Centers for Disease Control and Prevention announced that delivery of some swine flu vaccines has been delayed because companies cannot make as much as they had hoped.

Forty million doses had been expected in the country by the end of October, but only about 28 million to 30 million doses will be available.

Remley emphasized that this may cause a delay but not a shortage.

Meanwhile, flu cases continue to rise. Remley said about 6 percent of visits to the state's sentinel physicians are related to flu illnesses. The sentinel physicians track flu levels across the state.

"That's the highest it's been for the last two influenza seasons," Remley said.

The majority of flu strains reported are H1N1.

She said the state usually peaks at 4.5 percent in a season. She said that hospitals have been able to handle the increase in cases and there have not been any so-called "hospital surges," in which a facility could not handle the load.

Remley has previously said she had hoped everyone who wanted an H1N1 vaccine would have access to one by Thanksgiving. She said a more reasonable expectation due to the delay might be early December.

THE FLU CASE

French government says mass vaccination to start November 6th
after health personnel given jabs

La vaccination de la population débutera le 6 novembre

The Flu Case, 16 October 2009, 11:05
https://web.archive.org/web/20091201083253/http://www.theflucase.com/index.php?option=com_content&view=article&id=1105%3Afrench-government-says-mass-vaccination-to-start-november-6th-after-health-personnel-given-jabs&catid=1%3Alatest-news&Itemid=64&lang=en

The French government is pressing on with plans to mass vaccinate the entire population from November 6th with the GSK pandemrix vaccine -- a substance classified as a bioweapon by EU and US regulators – in spite of growing concerns over the safety of the jab.

Health personnel are to be the first group to be put under pressure by the government to take the jab in a push starting on October 20th.

Le ministère de la santé a réuni hier matin plusieurs dizaines d'acteurs hospitaliers – DGS, Samu de Paris, ordre des médecins… – afin de promouvoir la campagne de vaccination contre la grippe A(H1N1) des personnels des établissements de santé qui débutera mardi 20 octobre. Cette vaccination sera effectuée avec le vaccin Pandemrix adjuvanté (GSK). Une double injection est pour le moment recommandée. S'agissant de l'articulation avec la grippe saisonnière, il est précisé que «si la personne n'a pas encore été vaccinée», «l'administration du vaccin pandémique devient prioritaire».
La vaccination de la population devrait quant à elle débuter le vendredi 6 novembre dans les centres de vaccination.

THE FLU CASE

Barbara H. Peterson

Officials say:
Don't blame the Swine Flu shot, you'll drop dead anyway

InfoWars, The Flu Case, 16 October 2009
https://web.archive.org/web/20091020154519/http://www.theflucase.com/index.php?option=com_content&view=article&id=1122:officials-say-dont-blame-the-swine-flu-shot-youll-drop-dead-anyway&catid=1:latest-news&Itemid=64&lang=en

The H1N1 vaccination propaganda machine is going full-tilt, and the timetable for rapid population reduction is upon us. This is soooooo obvious, people! They are telling us what is going to happen before it happens, because they are going to cause it. They know people will drop dead after the shot, and are putting out the pre-op denial propaganda so that people will think, 'hey, they warned us of this, and it is nothing to worry about.'

Don't Blame Flu Shots for All Ills, Officials Say
=> https://web.archive.org/web/20111228010319/http://www.nytimes.com/2009/09/28/health/policy/28vaccine.html?_r=1
As soon as swine flu vaccinations start next month, some people getting them will drop dead of heart attacks or strokes, some children will have seizures and some pregnant women will miscarry. But those events will not necessarily have anything to do with the vaccine. That poses a public relations challenge for federal officials, who remember how sensational reports of deaths and illnesses derailed the large-scale flu vaccine drive of 1976. This time they are making plans to respond rapidly to such events and to try to reassure a nervous public – and headline-hunting journalists – that the vaccine is not responsible. Every year, there are 1.1 million heart attacks in the United States, 795,000 strokes and 876,000 miscarriages, and 200,000 Americans have their first seizure. Inevitably, officials say, some of these will happen within hours or days of a flu shot…
And just to make sure that this vaccine is as lethal as possible, Washington suspends the law regarding the amount of mercury it can have.

Washington OKs mercury in swine flu vaccine
https://web.archive.org/web/20090928112418/http://www.komonews.com/news/local/61285622.html#idc-ctools
The state Health Department will allow more mercury than usual in some of the swine flu vaccine to make sure shots are available to pregnant women and children under age three.
The department says mercury-free swine flu vaccine may not always be in stock, so it wants to give people the choice of using vaccine with the mercury preservative called thimerosal, which is believed to be safe.

The Centers for Disease Control's Web site says the following about thimerosal:
https://web.archive.org/web/20090928112418/http://www.cdc.gov/vaccinesafety/updates/thimerosal.htm
"There is no convincing scientific evidence of harm caused by the low doses of thimerosal in vaccines, except for minor reactions like redness and swelling at the injection site.
"However, in July 1999, the Public Health Service agencies, the American Academy of Pediatrics and vaccine manufacturers agreed that thimerosal should be reduced or eliminated in vaccines as a precautionary measure. Most vaccines for children under six are thimerosal-free."

The suspension of the mercury limit announced Thursday lasts six months and applies only to the swine flu vaccine expected to become available in October…

Here is the priority list of recipients for swine flu shots once the vaccine arrives:
– Anyone age 6 months to 24 years
– Pregnant women
– Healthcare workers
– People under 50 with chronic illnesses

I guess they are keeping to the time-honored tradition of women and children first, and as an added bonus, their shots will most likely have added mercury, since the clinical trials for the vaccine on pregnant women is scheduled to end approximately 9 days before the vaccine goes on the market for that target group.

I remember when the adjuvant Thimerosal (mercury) came out for horse vaccines. Horses were having a very bad reaction to it, and most people that I know of knew this and avoided them. Well, I guess if it is bad for horses, it must be good for people.

Mass Vaccination Schedule

The H1N1 vaccine was approved on September 15, 2009, with clinical trials done in mid-August for most adults. Vaccine clinical trials for pregnant women started on September 17, 2009, and a full-scale vaccination effort for all groups of people is set to begin in mid-October.

The FDA reported the following on September 15, 2009 regarding vaccine approval for most adults:

FDA Approves Vaccines for 2009 H1N1 Influenza Virus

https://www.cidrap.umn.edu/h1n1-2009-pandemic-influenza/fda-approves-four-companies-h1n1-vaccines

The H1N1 vaccines approved today undergo the same rigorous FDA manufacturing oversight, product quality testing and lot release procedures that apply to seasonal influenza vaccines. Testing began shortly thereafter for children, and the following was reported by ABC on September 17, 2009 regarding clinical trials for pregnant women: Twenty participants in the trial will get two doses 21 days apart and they'll be monitored in several different ways. Their cord blood will be checked too to see how it's affecting the unborn child.

On September 15, 2009, Reuters reported:

https://www.reuters.com/article/idUSN1562056/

U.S. officials are launching a large-scale vaccination effort in mid-October to inoculate the population, including those most at risk such as pregnant women and young people ages 6 months to 24 years.

Let's take a closer look at the clinical testing procedure. They start testing on pregnant women on September 15. The women get 2 doses, 21 days apart, and are tested. That would mean that on September 15, they would get the first dose, and 21 days later, Oct. 6, the second. The vaccination program is scheduled to start mid-Oct., which is around Oct. 15. That leaves approximately 9 days to determine that the vaccine is safe, and get it ready for distribution.

Running a pretty tight schedule there, eh? Jab 'em and if they don't drop dead in 21 days, jab 'em again. If they don't collapse on the second jab, then it's on to the public we go! So much for extensive testing. Wait, didn't I just read something about rigorous FDA testing? – "The H1N1 vaccines approved today undergo the same rigorous FDA manufacturing oversight, product quality testing and lot release procedures that apply to seasonal influenza vaccines," Dr. Jesse Goodman, FDA's acting chief scientist, said in a statement.

Just how rigorous can that testing be if between the last shot and full scale implementation on the population is a mere 9 days? Has anyone tried to get tests back from the lab lately? How long did it take? This is a done deal, folks. They don't care if people drop dead because the PR spin is already in high gear. In fact, they are boldly telling us what is going to happen before it happens, because they are going to cause it. They know people will drop dead or get sick after the shot, and are putting out the pre-op denial propaganda so that people will think, 'hey, they warned us of this, and it is nothing to worry about – it couldn't possibly be the vaccine, they said so.'

Let me tell you, if I look at someone and that person receives a vaccination, and then drops dead 5 minutes later, it was the vaccine! No amount of denial will convince me otherwise. This is a eugenics program, plain and simple. And as any good eugenics program goes, it is being forced on the public by any means possible.

IMPLEMENTING THE MASS VACCINATION PROGRAM

Let's look at how this vaccination program is being implemented. After all, it is supposed to be voluntary, right? After all, Obama said so. NOT! Here are the steps:

1. First they try and get you to comply through a propaganda campaign to effect voluntary compliance.
2. Second, they try and get you to take it under color of law.
3. Third, it becomes mandatory

The Propaganda Campaign

Any good vaccination propaganda campaign will start with the demonization of target groups to effect voluntary compliance. Propaganda is used to convince the public that the unvaccinated pose a threat to what is called "herd immunity." Herd immunity is defined by the Free Medical Dictionary as:

The resistance of a group to attack by a disease to which a large proportion of the members are immune.

If you take the vaccine, you are supposed to be immune, correct? If you don't take the vaccine, you are supposed to be susceptible to the virus. Why should the vaccinated worry about the unvaccinated if they are immune? If people do not want to take the vaccine and decide to protect themselves via natural methods, how does that affect supposed "herd immunity?" Are we a bunch of cattle that lose value if we get sick? The H1N1 is not a major health risk. The regular seasonal flu is worse than the H1N1 variety, and even health professionals refuse to take it. Yet, the propaganda goes on to convince people that if certain groups of people do not take the vaccine, then "herd immunity" is compromised, and everyone is in danger. Take this piece from the Yale Journal of Biology and Medicine:

Mandatory School Vaccinations: The Role of Tort Law; "Religious Communities as Disease "Hot Spots." [*further, there are excerpts the article* - https://www.ncbi.nlm.nih.gov/pmc/articles/PMC2553651/ Ciolli A. Mandatory school vaccinations: the role of tort law. Yale J Biol Med. 2008 Sep;81(3):129-37.]

Governments traditionally have considered "communities" in relatively broad terms, viewing entire states – or sometimes even the whole nation – as a "community" for herd immunity purposes [14]. However, recent experiences have demonstrated that actual communities are far smaller. For instance, although nationwide measles vaccination rates appeared high enough to ensure national herd immunity, disproportionately low vaccination rates among blacks and Hispanics resulted in measles outbreaks in several large urban areas, most notably Los Angeles [15].

Religious communities – particularly Christian Science, Amish, and Mennonite communities – have been the source of many preventable disease outbreaks in recent years. Diseases from polio [16] to measles [17] to rubella [18] have resurfaced with increasing frequency in the United States due to herd immunity being lost in such religious ghettos. This comes at a tremendous cost to society, for "vaccine-preventable diseases impose $10 billion worth of healthcare costs and over 30,000 otherwise avoidable deaths in America each year" [19]."

Religious ghettos? A typical propaganda technique and scare tactic – demonize the opposition, then accuse it of infecting others and lay blame. If people get sick because they do not take the vaccine, then your health care costs will go up. But wait, it gets better:

For decades, all 50 states have required that parents vaccinate their children against various diseases, including polio and measles, as a prerequisite to enrolling them in public schools [1]. While virtually all states have tailored their immunization statutes to exempt those with religious (and sometimes philosophical) objections to vaccines from these requirements [2], widespread use

of these exemptions threatens to undermine many of the benefits of mandatory vaccinations, such as preserving "herd immunity" [3]. Since it is unlikely that state governments will eliminate such exemptions outright, society must consider other methods of providing incentives for vaccination and compensating those who have suffered due to a disease outbreak caused by a community's loss of herd immunity.

Now the vaccinated become the victims of the unvaccinated because they may have suffered due to a disease outbreak caused by a lack of "herd immunity," and the unvaccinated can be threatened with a Tort lawsuit for "failure to vaccinate" if someone gets a disease and an unvaccinated person happens to be there.

The following article from Dr. Sherri Tenpenny shows how the Amish were used to advance "herd immunity" propaganda:

[Dr. Sherri Tenpenny. Polio "Non-Outbreak" Among the Amish. - The National Vaccine Information Center, 2 Dec 2005; ttps://www.vaccineinfo.net/news/Poliononoutbreak_Amish.shtml]

On October 14, [2005] the major media outlets shrieked a report of "the first outbreak of polio in the United States in 26 years," occurring in an Amish community in central Minnesota.

[David Brown. Polio Outbreak Occurs Among Amish Families In Minnesota. – Wasington Post, 14 October 2005] https://www.washingtonpost.com/archive/politics/2005/10/14/polio-outbreak-occurs-among-amish-families-in-minnesota/0fe0558f-dc8d-4052-8c1e-dce03759d9c1/

The specter of hundreds of children in braces and iron lung machines lining the halls of hospitals immediately danced through the air, and directly into the minds of parents who have chosen to not vaccinate their children.

"First of all, there wasn't an "outbreak of polio." There was only the discovery of an inactivated polio virus in the stool of four children. The first confirmation was in a 7-month old Amish infant, presumably hospitalized, with severe immune deficiency. The "find" prompted screening of other children in the community; four children were confirmed positive. None experienced any type of paralysis.

Part of the panic can be blamed on inaccurate reporting. The virus that was identified was not "wild polio." It was a virus that is found only in the oral polio vaccine (OPV). Oral vaccine-strain viruses are inactivated with formaldehyde and are generally considered by the CDC "too weak" to cause disease. Even though the OPV is still used extensively in Third World countries, it has not been used in the United States since 2000. How did children in an isolated Amish community, with no exposure to foreigners, become exposed to vaccine-strain polio virus? That remains a mystery.

Color of Law

Now let's take a look at what is known as the color of law. It is not against the law to not vaccinate your children. However, non-mandatory vaccinations do not have to be law to be mandatory. If the system around you forces you to do something against your will or suffer penalties for non-compliance via the back door approach such as the following example, then the result is the same as if there was a mandatory vaccination law.

Example: If your kids are enrolled in a public school, and you cannot homeschool them because of economics or other hardship, then you face mandatory vaccines. If you go the waiver route, then public officials can make it extremely difficult if not impossible to comply with the waiver requirements, and you end up violating an actual law requiring enrollment of your child in school. You've got to get them to school on time or face penalties for compulsory education violations because you refused the vaccinations and did not complete the waiver in time for the start of school. This is how non-mandatory becomes mandatory without being law, but is enforced under color of law.

Note: *color of law*. The appearance or semblance, without the substance, of a legal right. The term usually implies a misuse of power made possible because the wrongdoer is clothed with the authority of the state. State action is synonymous with color of [state] law in the context of federal civil-rights statutes or criminal law. See STATE ACTION. [Cases: Civil Rights 1323. C.J.S. Civil Rights §§ 92-94.] BLACK'S LAW DICTIONARY 282 (8th ed. 2004)

Mandatory Programs

When outright propaganda and color of law don't work, and not enough people take the vaccine, it becomes mandatory. All semblance of fair play is now thrown out, and the real motive becomes clear. Take the vaccine or else.

N.Y. Health Care Workers Revolt Over H1N1 Vaccine [WCBSTV, 30 Sept 2009]
https://web.archive.org/web/20091002191044/http://wcbstv.com/topstories/swine.flu.h1n1.2.1216352.html

They're upset over an ultimatum from the health department. Workers are being told to either get the swine flu vaccine or lose their jobs.

New York is the first state in the country to mandate flu vaccinations for its health care workers. The first doses of swine flu vaccine will be available beginning next week. Much of it is reserved for state health care workers, but there is growing opposition to required inoculations.

Health care workers in Hauppauge screamed "No forced shots!" as they rallied Tuesday against the state regulation requiring them to roll up their sleeves.

"I don't even tend to the sick. I am in the nutrition field. They are telling me I must get the shot because I work in a health clinic setting," said Paula Small, a Women, Infants and Children health care worker.

Small said she will refuse, worried the vaccine is untested and unproven, leaving her vulnerable. In 1976, there were some deaths associated with a swine flu vaccination.

Registered nurse Frank Mannino, 50, was also angry. He said the state regulation violates his personal freedom and civil rights. "And now I will lose my job if I don't take the regular flu shot or the swine flu shot."

When asked if he's willing to lose his job, Mannino said, "Absolutely. I will not take it, will not be forced. This is still America."

The protest also shook Albany Tuesday. Hundreds of demonstrators demanded freedom of choice. After all, as health care professionals they argue they're already constantly washing their hands and aren't likely to transmit or contract the flu.

Around 500,000 health care workers are slated to receive the vaccine.

"It's certainly their prerogative to voice their opinion," said Dr. Susan Donelan of Stony Brook University Hospital. Donelan said most in the medical community see the benefits and safety of the shots and welcome them, and that hospitals must obey the law. "Our hospital is committed to following the mandate to have our personnel vaccinated," she said.

The state said change was needed this year to save lives, typically only about 45 percent of health care workers take advantage of voluntary flu vaccines.

More than 150 institutional outbreaks of seasonal and H1N1 flu are expected this year in hospitals, nursing homes and hospice centers. New York and New Jersey will get their first doses of the swine flu vaccine next week. It will be the nasal mist, not a shot.

Dangers of Recombination

Now that we have looked at the supposed "rigorous testing procedures," the potentially harmful doses of mercury involved, and how a mandatory vaccination program is implemented, let's take a look at another danger that the vaccination program pushers don't want you to know about.

Jeffrey M. Smith shows us the dangers of genetically modified live virus vaccines, such as the H1N1:

GM Vaccines Recombine into Unpredictable Hybrid [*Seeds of Deception*]
https://web.archive.org/web/20091020035411/http://www.seedsofdeception.com/utility/showArticle/?objectID=39

In what may be the first experiment of its kind, scientists infected cell cultures with two related viruses. One was a genetically engineered poxvirus, (vaccinia virus (VIC) with a transgene from the influenza virus). The other was a naturally occurring relative of the first virus, isolated from Norwegian wildlife. Both were orthopoxviruses. The two viruses interacted and created many new hybrid viruses by recombination. The characteristics of some of the new viruses included traits not expressed in either parent virus. Some viruses, for example, spread faster than either parent, while

others produced different, more serious cell culture changes. A single virus multiplied into hundreds of thousands of viruses in a few hours, with unpredictable consequences. Since the marker gene in the transgenic virus was not present in some of the newly formed hybrid viruses, it would not be possible to track transgenic viruses as the origin of the hybrids, if they were found in the wild.

When a person receives a dose of the genetically engineered H1N1 live virus vaccine, that virus has the potential to recombine in the host. As with all live virus vaccines, the host will shed this newly recombined virus for around 21 days after inoculation. Persons who come in contact with the newly inoculated are subjected not to the original virus, but the newly recombined one thanks to genetic engineering. The new virus is potentially more lethal than the original live vaccine virus. This is the way to spread a lethal strain of flu to whatever segment of the population you are aiming to destroy. Create a virus via genetic engineering, inject as many as you can with it, and let nature do the rest.

The powers that be do not want anyone to know about the active shedding threat because they want the genetically modified recombined virus to spread just as far and wide as possible, thereby validating their fear mongering and creating more of a demand for the product (vaccine). This validation justifies all of the emergency measures already in place, such as quarantine facilities, forced vaccination checkpoints, etc.

It is a typical marketing ploy used in a most evil way.

Summation

We have a vaccine that has undergone such a limited "testing" that no sane person would willingly take it, the law regarding the amount of mercury allowed in vaccines has been suspended just so this one can have a bigger dose of it, and they are targeting pregnant women and children first.

The vaccine is supposedly voluntary, yet certain segments of the population are required to have it to keep their jobs. The health department has made mandatory the vaccines for health care workers already, and if not enough people take it to meet the "herd immunity" quota, it becomes mandatory for everyone. A certain percentage of the population has to take the shot to be active carriers in order to shed the virus to others to reduce the population to 500 mil, as required by eugenicists.

A Possible Scenario

I anticipate that we will have a window of opportunity that will last while the H1N1 flu shot volunteers run to the pharmas for their shot when they become available on or around October 15. There is a formula that is used to determine what percentage of the populace needs to be vaccinated to maintain "herd immunity," and the time schedule for forced vaccinations will be based on that, at least for a little while.

"*Herd immunity*" propaganda statistics will be used to implement forced vaccinations. If not enough people volunteer for the shots, "herd immunity" is supposedly compromised and a national health emergency can be declared, and people will buy into it.

When the live genetically modified virus recombines in the host and the vaccinated shed the newly mutated virus, people will be getting sick from having contact with the vaccinated, and this will reinforce the need for forced vaccinations to "solve the problem." More people will rush to get the vaccine "cure" and more live genetically modified virus will be passed on to others.

This will snowball into an all-out emergency event, which will involve the use of checkpoints, FEMA camps for quarantine, and martial law. We want to be off the streets as much as possible to avoid not only any quarantine and mandatory shot procedures, but also the mutated virus.

I hope I am wrong, but I am advising everyone reading this to be prepared just in case I am right.

REUTERS

Swine flu vaccines delayed, US CDC says

Reuters, 17 October 2009, 12:54 AM GMT+8
https://www.reuters.com/article/idUSN16358159/

Washington, Oct 16 (Reuters) - Delivery of some swine flu vaccines has been delayed because companies cannot make as much as they had hoped, the U.S. Centers for Disease Control and Prevention said on Friday.

The CDC's Dr. Anne Schuchat said while 40 million doses had been anticipated for the end of October, only about 28 to 30 million doses would be available.

"Yields for vaccine are lower than would be hoped," Schuchat said in a telephone briefing.

She also said deaths from H1N1 swine flu were above the epidemic threshold in some U.S. cities and states. H1N1 flu activity was widespread in 41 states, she said.

"It is unprecedented for this time of year to have the whole country having such high levels of activity," Schuchat said.

She also said more children had died in the space of a few weeks than usually die in an entire influenza season. "There are now a total of 86 children under 18 who have died from the 2009 H1N1 influenza virus," Schuchat said.

As of Wednesday 11.4 million doses of H1N1 vaccine were available and 8 million had been ordered by states for distribution.

The U.S. government has ordered vaccine from five companies: Sanofi-Aventis SA, CSL Ltd, Novartis AG, GlaxoSmithKline and AstraZeneca unitMedImmune.

Schuchat said 15 percent to 20 percent of patients with H1N1 who needed to be hospitalized were requiring intensive care.

Regierung bekommt eigenen Schweinegrippe-Impfstoff

Associated Press, AP, 17 Oktober 2009, 13:02 Uhr
https://web.archive.org/web/20091023231125/http://de.news.yahoo.com/1/20091017/thl-regierung-bekommt-eigenen-schweinegr-5e422d2.html

Berlin (AP) Die Kanzlerin, die Mitglieder ihres Kabinetts und Beamte der Ministerien sowie nachgeordneter Behörden sollen mit einem Impfstoff ohne Verstärker vor Schweinegrippe geschützt werden. «Wir haben 200.000 Dosen des nicht-adjuvantierten Impfstoffes Celvapan der Firma Baxter gekauft», sagte Christoph Hübner, Sprecher des Bundesinnenministeriums, dem Nachrichtenmagazin «Spiegel» laut Vorabbericht vom Samstag. Auch die Bundeswehr soll einen Impfstoff ohne Zusatz- und Konservierungsstoffe bekommen.

Anders als das Präparat von GlaxoSmithKline (GSK), das ab dieser Woche in 50 Millionen Dosen für die Bevölkerung ausgegeben wird, enthält der Baxter-Impfstoff keinen Wirkverstärker (»Adjuvans») und wird den für die Aufrechterhaltung der öffentlichen Ordnung zuständigen Staatsdienern gespritzt. Dazu zählen auch die Mitarbeiter des für die Impfstoffzulassung zuständigen Paul-Ehrlich- Instituts, das vergangene Woche wiederholt seine Entscheidung verteidigt hat, der Bevölkerung die GSK-Vakzine zu beschaffen.

«Behörden sind auf Kampagne reingefallen»

Für den Vorsitzenden der Arzneimittelkommission der deutschen Ärzteschaft, Wolf-Dieter Ludwig, ist das «ein Skandal», der den Menschen kaum zu vermitteln sei. «Wir sind unglücklich über diese Impfkampagne», sagte Ludwig. Sie werfe zahlreiche Probleme auf, ihr Nutzen sei ungewiss: «Die Gesundheitsbehörden sind auf eine Kampagne der Pharmakonzerne hereingefallen, die mit einer vermeintlichen Bedrohung schlichtweg Geld verdienen wollten.»

Weil der GSK-Impfstoff nicht an Schwangeren getestet wurde, muss auch für sie kurzfristig nicht-adjuvantierter Impfstoff besorgt werden. Der zuständige Staatssekretär im Bundesgesundheitsministerium, Klaus Theo Schröder, sagte dem Magazin: «Es laufen derzeit Gespräche mit Herstellern sowie den Gesundheitsministerien in Frankreich und den USA, mit dem Ziel, für Schwangere auch nicht-adjuvantierten Impfstoff zu beschaffen.»

«Schadensrisiko überwiegt den Nutzen»

Offene Rebellion herrscht laut «Spiegel» unter Allgemeinmedizinern und Kinderärzten. Der Präsident der Deutschen Gesellschaft für Allgemeinmedizin und Familienmedizin, Michael Kochen, rät den deutschen Hausärzten von der Impfung ab. «Das Schadensrisiko überwiegt den Nutzen», sagte der Göttinger Professor.

Wolfram Hartmann, Präsident des Berufsverbands der Kinder- und Jugendärzte, wirft der Bundesregierung «wissenschaftliche Falschaussagen» vor. Wie bei Schwangeren so gelte auch für Kinder unter drei Jahren: «Der Impfstoff ist an ihnen noch überhaupt nicht getestet, deshalb ist das Risiko einfach zu groß, ihn jetzt bedenkenlos einzusetzen.»

Kinder hätten ein Immunsystem, das zu Überreaktionen neige. Genau die aber könnten durch den Zusatz von Wirkverstärkern ausgelöst werden. Zusätzlich sei dem Impfstoff auch noch ein Quecksilber-haltiger Konservierungsstoff beigefügt. «Das Zeug hat man in heutigen Impfstoffen für Kleinkinder bewusst herausgehalten», sagte Hartmann.

Drei Impfstoffe in der EU zugelassen

In der EU sind bislang drei Impfstoffe gegen die Schweinegrippe oder Neue Grippe (H1N1) zugelassen: Focetria, Pandemrix und Celvapan. Focetria und Pandemrix enthalten verstärkende Zusatzstoffe, sogenannte Adjuvanzien. Allerdings kommt Celvapan nur deshalb ohne die umstrittenen Verstärker aus, weil es eine größere Konzentration an inaktivierten Schweinegrippe-Viren enthält als die beiden anderen Impfstoffe.

THE FLU CASE

Top German government officials to take special "swine flu" jab in new "scandal"

The Flu Case, 17 October 2009, 12:33
https://web.archive.org/web/20091030000644/http://www.theflucase.com/index.php?option=com_content&view=article&id=1130%3Adoctors-call-decision-by-top-german-government-officials-to-take-another-vaccine-a-qscandalq&catid=41%3Ahighlighted-news&Itemid=105&lang=en

The revelation that the German Chancellor Angela Merkel as well the cabinet, including the Health Minister Ulla Schmidt are planning to take a "swine flu" jab without mercury and squalene is fuelling fears in Germany that there is a two tier vaccination system planned; a safe vaccine for the global elite and their agents in national governments, and a lethal vaccine for the rest of the population.

Wolf Dieter Ludwig, head of the medicines commission of the association of German doctors, called the decision by the government to take a different vaccine from the untested and toxic swine flu jab destined for the rest of the population a "scandal" of a dimension that can hardly be communicated to the general public.

"The health authorities have fallen for a campaign from the pharmaceutical companies, who just want to earn money with an illusory threat," Ludwig said.

Vaccines with adjuvants have not been tested on pregnant women and children even though the German govenrment has said these are priority groups.

Among the government officials to get the "swine flu" jab without mercury and adjuvants will be the employees of the Paul Ehrlich Institute, the government drug regulator which ordered "swine flu" jabs with mercury and squalene to the rest of the population.

The Paul Ehrlich Institute ordered Pandemrix from GSK classified as a bioweapon by US and EU regulators.

In addition, the regulators recommended Celtura, a "new" vaccine from Novartis that appears to be the repacked version of Aflunov/Fluad H5N1 that killed homeless people in Poland in medical trials in 2008.

Novartis withdrew its application for EU-wide market approval of Aflunov/Fluad H5N1 from the European Medicines Agency in 2008. However, Novartis now appears to be pushing for a licence for the repackaged drug in Germany and Switzerland only.

The Paul Ehrlich Institute and Swissmedic are on the verge of granting approval to Celtura with the same MF59 squalene component as Aflunov/Fluad H5N1.

Concerns over the "swine flu" jab are being fuelled by the fact that the German army has insisted on getting a vaccine without mercury and adjuvants made by Baxter.

Baxter's Celvapan originally had mercury and adjuvants among its ingredients, but these appear to have been dropped under growing pressure from within Germany to have a safer vaccine.

Express & Star

Swine flu jab letters on way

Express & Star, 17 October 2009, 10:56
https://web.archive.org/web/20091021085822/http://www.expressandstar.com/2009/10/17/swine-flu-jab-letters-on-way/

Letters will start to go out over the next few weeks telling people in the West Midlands when they will receive swine flu jabs.

South Staffordshire Primary Care Trust was today the first in the region to confirm it was launching its vaccination programme.

Other PCTs in the region are expected to follow suit, offering vulnerable people and frontline medical staff their jab over the autumn.

John Wicks, flu director for South Staffordshire PCT, said: "Swine flu is generally mild for healthy people, but for pregnant women and those with health problems it can be more serious.

"The vaccine has had to pass stringent tests before being granted a licence by the European Medicines Agency and this means that we are very confident that the new vaccine is low risk.

"Just as soon as we receive supplies of the vaccine in South Staffordshire we will write directly to people within the key groups, prioritising the most vulnerable first, letting them know how and where they can receive their vaccination

SPIEGEL Wissenschaft

Kanzlerin und Minister sollen speziellen Impfstoff erhalten

Spiegel, 17 Oktobre 2009, 14.26 Uhr

https://www.spiegel.de/wissenschaft/medizin/schutz-vor-schweinegrippe-kanzlerin-und-minister-sollen-speziellen-impfstoff-erhalten-a-655764.html

Kanzlerin und Minister sollen nach SPIEGEL-Informationen mit speziellem Impfstoff vor Schweinegrippe geschützt werden. Beamte von Ministerien und nachgeordneten Behörden ebenso. Das Vakzin enthält keine umstrittenen Zusatzstoffe - im Gegensatz zum Impfstoff für den Rest der Bevölkerung.

Berlin - Bis vor wenigen Tagen hatte kaum jemand außerhalb von Fachzirkeln das Wort Adjuvans gehört. Doch nun ist eine öffentliche Diskussion über die Zusammensetzung des Impfstoffs für die demnächst anlaufende Schweinegrippeimpfung entflammt. Dabei taucht immer wieder der Begriff auf, mit dem ein Zusatzstoff zur Wirkverstärkung bezeichnet wird.

Kritiker argumentieren, dass Adjuvantien zu gesteigerten Impfreaktionen wie Kopfschmerzen oder Fieber führen könnten. Unterstützer halten dagegen, dass die Impfung auch mit den Zusatzstoffen sicher sei - und dass auf diese Weise mehr Wirkstoffdosen hergestellt werden könnten. Vor einigen Tagen hatte die Bundeswehr bekanntgegeben, dass sie für ihre Soldaten einen Impfstoff ohne Zusatzstoffe geordert hat.

Doch nach SPIEGEL-Informationen sollen auch weitere Personengruppen eine Impfung ohne Adjuvantien erhalten: "Wir haben 200.000 Dosen des nicht-adjuvantierten Impfstoffs Celvapan der Firma Baxter gekauft", räumt Christoph Hübner, Sprecher des Bundesinnenministeriums ein. Anders als das Präparat von GlaxoSmithKline (GSK), das ab kommender Woche in 50 Millionen Dosen für die Bevölkerung ausgegeben wird, enthält der Baxter-Impfstoff keinen Wirkverstärker.

Allerdings kommt Celvapan nur deshalb ohne die umstrittenen Hilfsstoffe aus, weil es ganze abgetötete Viren und nicht Virenbruchstücke enthält. Die Substanz wird den für die Aufrechterhaltung der öffentlichen Ordnung zuständigen Staatsdienern gespritzt: Mitgliedern des Kabinetts sowie Beamten der Ministerien und der nachgeordneten Behörden. Dazu zählen auch die Mitarbeiter des für die Impfstoffzulassung zuständigen Paul-Ehrlich-Instituts, das vergangene Woche wiederholt seine Entscheidung verteidigt hat, der Bevölkerung die GSK-Vakzine zu beschaffen.

"Gesundheitsbehörden sind auf Pharmakonzerne hereingefallen"

Für den Vorsitzenden der Arzneimittelkommission der deutschen Ärzteschaft, Wolf-Dieter Ludwig, ist das ein Skandal, der den Menschen kaum zu vermitteln sei. "Wir sind unglücklich über diese Impfkampagne", so Ludwig weiter. Sie werfe zahlreiche Probleme auf, ihr Nutzen sei ungewiss: "Die Gesundheitsbehörden sind auf eine Kampagne der Pharmakonzerne hereingefallen, die mit einer vermeintlichen Bedrohung schlichtweg Geld verdienen wollten."

Weil der GSK-Impfstoff nicht an Schwangeren getestet wurde, muss auch für sie kurzfristig nicht-adjuvantierter Impfstoff besorgt werden. Das zuständige Thüringer Gesundheitsministerium hatte am

Freitag erklärt, man verhandle mit verschiedenen Herstellern über einen begrenzten Nachkauf von Impfstoff ohne die umstrittenen Hilfsstoffe. Der Staatssekretär im Bundesgesundheitsministerium, Klaus Theo Schröder, bestätigte das gegenüber dem SPIEGEL: "Es laufen derzeit Gespräche mit Herstellern sowie den Gesundheitsministerien in Frankreich und den USA, mit dem Ziel, für Schwangere auch nicht-adjuvantierten Impfstoff zu beschaffen."

Offene Rebellion herrscht unter Allgemeinmedizinern und Kinderärzten. Der Präsident der Deutschen Gesellschaft für Allgemeinmedizin und Familienmedizin, Michael Kochen, rät den deutschen Hausärzten von der Impfung ab. "Das Schadensrisiko überwiegt den Nutzen", sagt der Göttinger Professor. Wolfram Hartmann, Präsident des Berufsverbands der Kinder- und Jugendärzte, wirft der Bundesregierung "wissenschaftliche Falschaussagen" vor. Wie bei Schwangeren, so gelte auch für Kinder unter drei Jahren: "Der Impfstoff ist an ihnen noch überhaupt nicht getestet, deshalb ist das Risiko einfach zu groß, ihn jetzt bedenkenlos einzusetzen."

Two Flu Vaccines, Lots of Questions

The Wall Street Journal, 18 October 2009 12:01 am ET
https://www.wsj.com/articles/SB125582035965192331

The annual ritual of fending off the flu is more complicated this fall as Americans weigh getting two vaccines.

The vaccine to fight seasonal flu is already widely available, although some areas have reported supply shortages or delays. But a new vaccine to protect against the H1N1 virus, commonly known as swine flu, is just starting to make its way to schools, public-health departments and doctors' offices.

Because of an initial limited supply, the first doses of the swine-flu vaccine are earmarked for people with a high risk of getting serious complications from the swine flu and for those at risk of spreading the illness to them.

States have ordered about eight million doses of the H1N1 vaccine so far, with the potential for up to 250 million total doses, depending on demand, says Tom Skinner, spokesman for the federal Centers for Disease Control and Prevention in Atlanta.

One Shot or Two?

Public-health officials say everyone who wants a swine-flu vaccine eventually will be able to get one free. But many people are still wondering if they need ...

Two Flu Vaccines, Twice the Number of Questions

RisMedia, 20 October 2009
https://www.rismedia.com/2009/10/20/two-flu-vaccines-twice-the-number-of-questions/

Rismedia, October 21, 2009 – (MCT) – The annual ritual of fending off the flu is more complicated than usual this fall as Americans weigh the opportunity to receive two vaccines to protect against different types of influenza.

The vaccine to fight seasonal flu is already widely available to people of all ages and health conditions, although some areas have reported supply delays or shortages. But a new vaccine to protect against the H1N1 virus, commonly known as swine flu, is just starting to make its way to schools, public health departments and doctors' offices.

Because of an initial limited supply, the first doses of swine flu vaccine are earmarked for people at high risk of serious complications from swine flu and those at risk of spreading it to them.

States have ordered about 8 million doses so far, with the potential for up to 250 million total doses, depending on demand, according to the Centers for Disease Control and Prevention in Atlanta. Public health officials say everyone who wants a swine flu vaccine eventually will be able to get one as more come on line.

The first question many people are asking is if they need one or both of the vaccines. Nearly all Americans, or 88% of the population fall into a group that's recommended to receive the seasonal flu vaccine, said CDC spokesman Tom Skinner. About half the population fits into a category deemed high priority for the swine flu vaccine. "People who are recommended to get those vaccines need to plan to get both of them," Skinner said.

While some flu cases involve only several days of misery, others go on to become life-threatening or even fatal. Since the swine flu emerged in the U.S. in April, more than 800 people with flu symptoms have died, including 28 pregnant women and 86 children. Most of those children had an underlying condition, but 20% to 30% of them were otherwise healthy. The seasonal flu sends an average of 200,000 Americans to the hospital and kills 36,000 of them every year. People who've come down with a flu-like illness recently may think they had swine flu and that they no longer need a vaccine to prevent it.

But there are hundreds of other respiratory viruses circulating with symptoms that often overlap, and people with mild cases of suspected flu aren't sent for laboratory confirmation of the H1N1 virus, making it impossible to know for sure if they've built immunity, said Dr. Greg Poland, director of the Vaccine Research Group at the Mayo Clinic in Rochester, Minn. "Because there's no harm in getting the vaccine even if you think you had swine flu, we err on the side of caution and say you should get the vaccine," Poland said.

While vaccination doesn't confer 100% protection against the flu, it's still the most effective way to prevent it or mitigate its harm to the body, according to the CDC.

Clinical trials of the H1N1 vaccine showed it has many of the same side effects as the seasonal variety, chiefly a sore arm at the injection site. People with a known allergy to chicken eggs and

those with suppressed immune systems should talk to their doctor about whether flu vaccination is an option for them.

The swine flu vaccine is manufactured the same way as its seasonal counterpart, and the H1N1 strain may have been included in this year's seasonal vaccine had the virus emerged a few months earlier when planning for the seasonal vaccine was under way, said Dr. Paul Offit, chief of infectious disease at the Children's Hospital of Philadelphia.

The seasonal flu vaccine has been used for decades in formulations that change every year to reflect the three most dominant strains of virus that scientists believe will be circulating when the vaccine goes into production in the spring. The swine flu virus makes up the vast majority of flu bugs now going around and people in high-risk groups are urged to get a swine flu vaccine as soon as they become available. The groups who are first priority are pregnant women, children and young adults age 6 months to 24 years old, people who are around children too young to be immunized, those age 25 to 64 who have underlying chronic medical conditions such as diabetes or asthma, and health care workers.

More people are recommended to be vaccinated against seasonal flu since, unlike swine flu, it tends to hit the elderly hard as well. About 82 million doses of that vaccine have shipped, and manufacturers are expected to produce about 114 million doses total this year.

"The reason to get both is you want to be protected from the strains most likely to circulate," Offit said. People who want one or both vaccines may have to be patient until more supply arrives, and they're wise to call ahead to see if the vaccines they want are available. They also should ask about price and insurance coverage. Some employers and health insurers offer discounts or full reimbursement for flu vaccines. Medicare beneficiaries can receive both vaccines free of charge after satisfying their Part B deductible. The swine flu vaccine is free for anyone who wants it, though health care providers may charge an administration fee. Uninsured and underinsured children may receive free vaccines through the government's Vaccines for Children Program. There is high demand for seasonal flu vaccine at Walgreens stores around the country, said company spokesman Jim Cohn in Deerfield, Ill. This year Walgreens is offering the seasonal flu vaccine seven days a week either by appointment or on a walk-in basis. The cost without Medicare or private insurance is $24.99 for the shot and $29.99 for the nasal-spray version.

"I would strongly encourage people interested in getting a seasonal vaccine to do so as soon as possible because we're hearing about shortages or locations that are out of the vaccine already," Cohn said.

"We now have the industrial capacity to make a lot of vaccine efficiently and quickly, and that's good," Offit said. "But what we don't have yet is the distribution method to allow for easy, quick and efficient vaccination."

For people who choose to get either or both flu vaccines, the next questions are often what form they should pick – the shot or the nasal spray – and how far apart the immunizations should be if they get both the regular and swine flu vaccines.

Only healthy people ages 2 to 49 who aren't pregnant can receive the nasal-spray versions. People who fit that criteria and are looking to avoid needles for both flu vaccines need to wait four weeks between the two nasal-spray versions, said the CDC's Skinner. Children ages 6 months to 9 years who have never received a flu vaccine before are recommended to receive two doses of both the H1N1 and seasonal flu vaccine about a month apart, Offit said. People age 10 and older need only one dose of swine flu vaccine, according to the CDC.

https://web.archive.org/web/20091024100919/http://www.theflucase.com/index.php?option=com_content&view=article&id=1160%3Afrench-mass-vaccination-campaign-to-start-tomorrow-health-workers-to-get-the-jab-first&catid=41%3Ahighlighted-news&Itemid=105&lang=en

La campagne de vaccination contre la grippe A(H1N1) commencera mardi en France pour le personnel hospitalier, annonce le ministère de la Santé dans un communiqué.

Celle pour les citoyens débutera "après les vacances de la Toussaint (qui se terminent le 5 novembre-NDLR), dans l'ordre de priorité défini par le Premier ministre", a ajouté le ministère, joint par Reuters.

Les citoyens prioritaires sont les femmes enceintes, l'entourage des nourrissons de moins de six mois et les nourrissons de six à 23 mois avec des facteurs de risque.

La ministre de la Santé, Roselyne Bachelot, présentera mardi à 10h00 (08h00 GMT) la campagne de vaccination lors d'une conférence de presse au ministère, à Paris.

La France a commandé 94 millions de doses du vaccin contre la grippe A (H1N1) auprès des groupes Sanofi, Novartis, GlaxoSmithKline et Baxter.

French mass vaccination campaign to start tomorrow: health workers to get the jab first

The Flu Case, 19 October 2009

France's military-style mass "swine flu" vaccination programme is due to start on Tuesday with the vaccination of health personnel, French Health Minister Roselyne Bachelot has said.

The "swine flu" jab campaign for the rest of the population is to start "after the All Saints holiday in the order of priority defined by the Prime Minister," she said.

Pregnant women and small children are to be among the first to receive the jab even there is no clinical data on the impact of the jab with adjuvants on these groups. Mobile pandemic vaccination teams are ready to go to schools and give children the jab by force.

The jab contains mercury and squalene, known to causes diseases, including autoimmune diseases. About 25 % of the US and UK soldiers who received an anthrax vaccine containing squalene developed autoimmune and other diseases known as the Gulf War Syndrome about a year after they got the jab.

Squalene is illegal in the USA and UK. The "swine flu" jab contains a million times more squalene than the anthrax jab that damaged US and UK soldiers.

Grippe A: les généralistes ne sont pas prêts pour la campagne de vaccination

RTBF, 19 Oct.obre 2009, 15:13
https://www.rtbf.be/article/grippe-a-les-generalistes-ne-sont-pas-prets-pour-la-campagne-de-vaccination-5376293

"Le système d'enregistrement et de rémunération n'est pas clair", estime lundi Jos De Smedt de Domus Medica dans la presse *flamande*.

Selon Jos De Smedt, les généralistes qui reçoivent des patients à risque ne savent pas précisément comment cette campagne de vaccination gratuite doit se dérouler.

"Des médecins wallons ainsi que quelques médecins flamands ont refusé de s'enregistrer et nous ne savons pas combien de vaccinations sont nécessaires et si nous pouvons vacciner plus tôt des patients qui présentent un risque élevé."

La première phase de la campagne de vaccination contre la grippe A/H1N1 démarre lundi dans toute la *Belgique*. L'entiereté du groupe des patients à risque peut se faire vacciner chez le généraliste à partir du 1er novembre.

Bankkaufmann.com

Statement GlaxoSmithKline zur Vorab-Meldung des Spiegels vom 17.10.2009
zu den Pandemie-Impfstoffen und der Bestellung für die Bundesregierung

Bankkaufman, 19 Oktober 2009
https://www.bankkaufmann.com/a-231552-Statement-GlaxoSmithKline-zur-Vorab-Meldung-des-Spiegels-vom-17102009-zu-den-Pandemie-Impfstoffen-und-der-Bestellung-f.html%C3%BCr-die-Bundesregierung

München (ots) - GlaxoSmithKline nimmt zur Vorab-Meldung im Spiegel (online) wie folgt Stellung:

Die Entscheidung des Innenministeriums, einen anderen Impfstoff für die Bundesregierung zu bestellen als für die Gesamtbevölkerung, ist legitim. Hingegen rechtfertigt diese Entscheidung keinen Rückschluss auf eine Differenzierung in bessere oder schlechtere Impfstoffe - Pandemrix® ist wie zwei weitere Impfstoffe von der Europäischen Zulassungsbehörde EMEA am 30. September 2009 zur Verwendung in 27 Mitgliedsländern zugelassen worden.

Der Pandemie-Impfstoff besteht aus dem spezifischen H1N1-Virus-Antigen und dem Adjuvanssystem AS03. Dies wurde eigens von GSK entwickelt und hat den Vorteil, dass der Impfstoff Antigen-sparend hergestellt werden kann - vor dem Hintergrund weltweit begrenzter Produktionskapazitäten für Pandemie-Impfstoffe ist es somit möglich, wesentlich mehr Menschen zu impfen und die Pandemie somit wirksamer einzudämmen.

Darüber hinaus wird erwartet, dass durch das Adjuvanssystem auch verwandte Virusstämme durch eine mögliche Kreuzprotektion bekämpft werden können.

Die Ergebnisse einer weiteren klinischen Studie zum H1N1-Impfstoff an 2.000 Impflingen bestätigen die allgemein gute Verträglichkeit. Bereits zuvor wurde das Verträglichkeitsprofil von den Behörden als positiv bewertet. Das Adjuvanssystem AS03 wurde im Rahmen von Grippe-Studien an insgesamt über 39.000 Probanden getestet und erwies sich als gut verträglich.

GlaxoSmithKline legt Wert auf die Feststellung, dass das Unternehmen weder zum Verlauf der Pandemie sowie ihrer möglichen Folgen Prognosen abgegeben oder gar Kampagnen gefahren hat - weder öffentlich noch bei Vertrags-Verhandlungen. Anders lautende Behauptungen sind aus der Luft gegriffen und entbehren jeder Grundlage. Überdies ist GlaxoSmithKline nicht der einzige Hersteller von Pandemie-Impfstoffen - somit stand der Bundesregierung wie auch anderen Regierungen die Wahl des zu beziehenden Impfstoffes frei.

Die Bundesregierung hat mit ihrem Entwicklungs- und Produktions-Auftrag eines Pandemie-Impfstoffs gegen die Influenza A (H1N1) sowie auch mit der bestellten Menge eine seinerzeit sehr verantwortungsvolle Entscheidung getroffen - auch im Einklang mit Vorgaben und Empfehlungen der WHO und der zuständigen Impf-Institute.

Bislang haben 22 Regierungen weltweit rund 440 Millionen Dosen von Pandemrix® bestellt, mit weiteren führt das Unternehmen Gespräche.

Dies wurde eigens von GSK entwickelt und hat den Vorteil, dass der Impfstoff Antigen-sparend hergestellt werden kann – vor dem Hintergrund weltweit begrenzter Produktionskapazitäten für Pandemie-Impfstoffe ist es somit möglich, wesentlich mehr Menschen zu impfen und die Pandemie somit wirksamer einzudämmen.

Darüber hinaus wird erwartet, dass durch das Adjuvanssystem auch verwandte Virusstämme durch eine mögliche Kreuzprotektion bekämpft werden können.

Die Ergebnisse einer weiteren klinischen Studie zum H1N1-Impfstoff an 2.000 Impflingen bestätigen die allgemein gute Verträglichkeit. Bereits zuvor wurde das Verträglichkeitsprofil von den Behörden als positiv bewertet. Das Adjuvanssystem AS03 wurde im Rahmen von Grippe-Studien an insgesamt über 39.000 Probanden getestet und erwies sich als gut verträglich.

GlaxoSmithKline legt Wert auf die Feststellung, dass das Unternehmen weder zum Verlauf der Pandemie sowie ihrer möglichen Folgen Prognosen abgegeben oder gar Kampagnen gefahren hat - weder öffentlich noch bei Vertrags-Verhandlungen. Anders lautende Behauptungen sind aus der Luft gegriffen und entbehren jeder Grundlage. Überdies ist GlaxoSmithKline nicht der einzige Hersteller von Pandemie-Impfstoffen – somit stand der Bundesregierung wie auch anderen Regierungen die Wahl des zu beziehenden Impfstoffes frei.

Die Bundesregierung hat mit ihrem Entwicklungs- und Produktions-Auftrag eines Pandemie-Impfstoffs gegen die Influenza A (H1N1) sowie auch mit der bestellten Menge eine seinerzeit sehr verantwortungsvolle Entscheidung getroffen – auch im Einklang mit Vorgaben und Empfehlungen der WHO und der zuständigen Impf-Institute.

Bislang haben 22 Regierungen weltweit rund 440 Millionen Dosen von Pandemrix® bestellt, mit weiteren führt das Unternehmen Gespräche.

THE FLU CASE

GlaxoSmithKline says German government has the right to order different "swine flu" jab from the rest of population

The Flu Case, 19 October 2009, 10:17
https://web.archive.org/web/20091023065848/http://www.theflucase.com/index.php?option=com_content&view=article&id=1157%3Aglaxosmithkline-says-german-government-has-the-right-to-order-different-qswine-fluq-jab-from-the-rest-of-population&catid=1%3Alatest-news&Itemid=64&lang=en

GlaxoSmithKline has issued a press statement in which the company defends the decision by the German government to order a totally different "swine flu" vaccine from the rest of the population which will be given a jab with the soft kill ingredients of mercury and the adjuvant, squalene.

GSK claims that there is no difference in the quality between the vaccine the German government has ordered for itself and the "swine flu" jab that the rest of the population is expected to take, arguing that GSK's pandemrix has received approval from the European Medicines Agency.

What GSK omits to mention is that the EMEA approval has been given under special "pandemic emergency" procedures which allow vaccines that have not been tested for safety and efficacy to be given to people.

GSK also fails to mention that Novartis' Aflunov/Fluad H5N1 was also about to be registed by the EMEA under standard procedures before Novartis had to withdraw the drug for manipulating clinical data after it transpired it had killed people in trials in Poland, trials only uncovered by the police.

Squalene has been found to be the cause of autoimmune diseases, specifically the Gulf War Syndrome and is illegal in the US and UK. Nowhere does GSK mention these facts.

Also, GSK fails to mention its Pandemrix "swine flu" jab is classified as a bioweapon by EU and US regulators: it has not been tested on pregnant women or children - even though these are the target groups selected by the German government.

GSK also fails to mention that WHO has mandated a vaccine with mercury and adjuvants for everyone, making the decision by the German govenrment to order a totally different vaccine hard to explain.

The reality is that the German government has ordered the equivalent of "sugar" and "cyanide" for the rest of the population - and GSK is knowingly and deliberately delivering that cyanide and mispresenting the scientific evidence in order to justify doing go.

Scots swine flu jab drive set to target 130,000 Scots every week

The Flu Case, 19 October 2009
https://web.archive.org/web/20091024035629/http://theflucase.com/index.php?option=com_content&view=article&id=1163%3A130000-scots-every-week-to-get-qswine-fluq-jab-publicity-campaign-planned&catid=41%3Ahighlighted-news&Itemid=105&lang=en

HEALTH officials are preparing for a publicity offensive to encourage as many Scots as possible to have the swine flu vaccine in efforts to limit the impact of the pandemic in Scotland.

The NHS plans to vaccinate 1.3 million people in at-risk groups by the end of the year, meaning around 130,000 a week will have to receive the jab.

But the programme, which starts on Wednesday, is dependent on the drugs manufacturers delivering enough supplies of vaccines to all four nations of the UK.

A publicity campaign is now being planned to encourage those in the priority groups for the jab – including pregnant women and those with chronic health problems – to have the vaccine once invited by their GP.

Yesterday, health secretary Nicola Sturgeon warned that "bigger challenges" were in store with the pandemic in Scotland.

She told the SNP conference in Inverness that prevention is better than cure in dealing with swine flu. "That is why our best defence will be vaccination," she said. "Our vaccination programme will begin on Wednesday. It will take time to complete but by the end of this year, we will have offered vaccine to 1.3 million Scots, including frontline health staff and those most at risk of complications.

"Now I know that some people worry about vaccines. I know that there are those who think vaccination is not necessary. But make no mis- take, swine flu can kill and this vaccine will save lives."

The swine flu vaccination programme will begin on Wednesday, with patients in hospital getting the jab first.

Next week, GPs will start inviting certain patients to be vaccinated. People are being urged to wait until they receive a letter from their doctor before turning up at their surgery for vaccination.

Skepsis gegenüber Impfstoff

ÄrzteZeitung

Verteilung des Schweinegrippe-Impfstoffs ist angelaufen

Arzte Zeitung, 19 Oktobre 2009, 15:00 Uhr
https://www.aerztezeitung.de/Wirtschaft/Verteilung-des-Schweinegrippe-Impfstoffs-ist-angelaufen-372894.html

Berlin (dpa/ ger). In Deutschland hat die Verteilung des Impfstoffs gegen die Schweinegrippe begonnen. Pünktlich um sieben Uhr seien am Montag die ersten Dosen ausgeliefert worden, sagte eine Sprecherin des Pharma-Unternehmens GlaxoSmithKline (GSK) auf Anfrage.

Der genaue Ort der Auslieferung an die Bundesländer in der Nähe von Dresden ist vom Unternehmen GSK nicht bekannt gegeben worden, um den reibungslosen Ablauf nicht zu gefährden. Die Bundesländer bekommen den Impfstoff nach einem zuvor festgelegten Zeitplan, der dafür sorgen soll, dass keines der Bundesländer im Vergleich zu den anderen im Vorteil oder im Nachteil ist.

GSK betonte in einer Stellungnahme, die Entscheidung der Regierung, einen anderen Impfstoff für die Bundesregierung zu bestellen als für die Gesamtbevölkerung, sei legitim. Sie rechtfertige jedoch keinen Rückschluss auf eine Differenzierung in bessere oder schlechtere Impfstoffe. Von der Europäischen Zulassungsbehörde EMEA seien am 30. September gleichzeitig drei Impfstoffe zur Verwendung zugelassen worden. Das Adjuvans ermögliche es, in der Pandemie Impfstoff für mehr Menschen herzustellen. Es werde erwartet, dass damit auch verwandte Virusstämme bekämpft werden könnten.

GSK lege Wert darauf, dass das Unternehmen "weder zum Verlauf der Pandemie sowie ihrer möglichen Folgen Prognosen abgegeben oder gar Kampagnen gefahren hat - weder öffentlich noch bei Vertrags-Verhandlungen". Die Bundesregierung habe mit ihrem Entwicklungs- und Produktions-Auftrag eines Pandemie-Impfstoffs gegen H1N1 eine Entscheidung im Einklang mit Vorgaben und Empfehlungen der WHO und der zuständigen Impf-Institute getroffen. Bislang seien weltweit 440 Millionen Impfdosen von Pandemrix® bestellt worden.

Die Debatte über den Impfstoff gegen die Schweinegrippe droht nach Einschätzung des Thüringer Gesundheitsministeriums, die Impfbereitschaft zu dämpfen. "Die Diskussion um einen vermeintlich besseren Impfstoff für Bundeswehr und Bundesregierung wirkt demotivierend", sagte Ministeriumssprecher Thomas Schulz.

Die Bundeskanzlerin will sich nach Angaben von Regierungssprecher Ulrich Wilhelm wie bisher von ihrem Hausarzt über die Impfung beraten lassen. Sollte sie sich für eine Immunisierung entscheiden, werde sie Pandemrix® erhalten, sagte er. Dieser Impfstoff sei auch vom Paul-Ehrlich-Institut (PEI) für seine Beschäftigten geordert worden, so das PEI. Eine Umfrage hatte vergangene Woche ergeben: Nur jeder dritte Bundesbürger will das Angebot zur Schweinegrippe-Impfung annehmen.

Swine flu vaccine delays prompt worries as flu cases spike

The Mercury News, 19 October 2009, 12:42 p.m.
https://www.mercurynews.com/?G2I_ActionId=123442&returnUrl=https%3A%2F%2Fwww.mercurynews.com%2F2009%2F10%2F19%2Fswine-flu-vaccine-delays-prompt-worries-as-flu-cases-spike%2F%3FclearUserState%3Dtrue

With swine flu spreading through Santa Clara County and the vaccine's distribution being delayed, there's growing concern among some that once the H1N1 vaccine is widely distributed, it will be too little too late.

Since the swine flu outbreak last spring, a rush has been on to develop and distribute the vaccine in time to thwart the virus's spread, with promises of mid-October delivery dates. But with manufacturing delays causing a 25 percent drop in the anticipated doses available this month, clinics designed to inoculate thousands of residents have been delayed and San Jose Unified has postponed its plans to offer free vaccines to schoolchildren until mid-November.

Even some families going to their pediatricians' offices are being turned away.

"The flu season has started in earnest, and by the time the children get the vaccine – at the end of October at the earliest, it appears – there will be a lot more flu circulating," said Alisa Yaffa, a Menlo Park mother of two school-age children.

With the children of two of her good friends out sick, Yaffa was so anxious to get her children vaccinated that she has tried not only her pediatrician's office and Safeway, but also the Santa Clara and San Mateo county health departments – all to no avail.

Last week, as many as 179 people a day came to six hospital emergency rooms in Santa Clara County complaining of fever, one of the main symptoms of swine flu. Those patients are presumed to have swine flu, even without a test, because the H1N1 virus is the primary virus spreading now. Seasonal flu hasn't really kicked in yet.

"It reinforced the idea that we have H1N1 in our community, that we have a widespread outbreak of this infection and increasing numbers of people who are getting sick," Santa Clara County's public health officer, Marty Fenstersheib, said last week.

The string of five Gardner Family Health Network clinics in San Jose and Gilroy also saw a spike last week in people coming in with flulike symptoms, with 137 cases total. Gardner plans to offer vaccination clinics at its sites beginning Nov. 7, assuming it receives a sufficient supply by then.

"All our clinic managers have ordered" vaccines, said Kay Henderson, the quality improvement director for the clinics. "However, we've not received it."

San Jose Unified faced the same problem, forcing the 32,000-student district to delay its districtwide inoculation plans. Officials had hoped to start two vaccination pilot programs by Halloween, but will have to delay them by a couple of weeks though officials said the delay gives them extra time to plan.

Two weeks ago, the state shipped 14,100 doses of H1N1 vaccine to doctors offices, hospitals and clinics in Santa Clara County. Of that, Fenstersheib's office received 500 doses, and has already sent them out to a number of pediatricians' offices who either didn't receive any or were running low.

The next big shipment is expected at the end of October or early November, said Joy Alexiou, spokeswoman for the county health department.

"People need to be patient until more of the vaccine is provided," Alexiou said. "We will have missed the October time frame, but I don't think by October everyone will have gotten the flu. I think there will be a number of people whom this vaccine will protect this winter."

Foothill Community College in Los Altos Hills was hoping to get in front of the problem and prevent a big outbreak there. It planned to open a weeklong vaccine clinic starting Monday and inoculate as many as 1,000 students and employees a day. But a delay in vaccine shipments forced the school to cancel, even though two or three students a day enter the health clinic with flu-like symptoms.

"Like everyone in the health services right now, it's a frustrating situation to know that this vaccine could help prevent what we call a pandemic," Naomi Kitajima said, director of the campus health services center, who was shocked to learn from a county Web site that she might get less than half the vaccines she ordered. "I'm very anxious to get it."

Kaiser is using its limited supply of the vaccine for children who already have "well-child" appointments scheduled. When it receives more vaccine, expected later this week, it will start to expand the availability to a broader group of high risk people.

DERSTANDARD

Impfstoff unterwegs nach Österreich
Empörung über "Zweiklassenmedizin" in Deutschland

Der Sstandard, 19 Oktober 2009, 21:18
https://www.derstandard.at/story/1254311839355/impfstoff-unterwegs-nach-oesterreich

Wien/Berlin - Der von Österreich bestellte Schweinegrippe-Impfstoff ist bereits unterwegs, wurde Montagabend der Austria Presseagentur bestätigt. Gesundheitsprofessionisten sind die Ersten, die am 27. Oktober zur Massenimpfung antreten dürfen. Ab 9. 11. ist dann der Rest der Bevölkerung dran, zuerst werden chronisch kranke Personen und Schwangere bevorzugt. Die Kosten für die freiwillige Impfung übernehmen die Krankenversicherungen, bezahlt werden muss lediglich die Rezeptgebühr.

Für Politiker gibt es, im Gegensatz zu Deutschland, in Österreich keine Extrawürstel. In der Alpenrepublik gibt es ausschließlich den Baxter-Impfstoff Celvapan, bestätigte am Montag Thomas Geiblinger, der Sprecher von Gesundheitsminister Alois Stöger, auf Standard-Anfrage. Falls notwendig, können 16 Millionen Dosen geliefert werden. Celvapan kommt ohne verstärkende Zusatzstoffe aus, enthält dafür aber eine größere Konzentration an inaktivierten Schweinegrippe-Viren.

In Deutschland hingegen sorgt die Impfaktion gegen die Schweinegrippe für große Aufregung. Seit Montag werden bundesweit 50 Millionen Dosen Pandemrix, hergestellt von der Firma GlaxoSmithKline (GSK), an Ärzte und Gesundheitsämter ausgeliefert. Das ist das Serum für das "normale Volk" . Doch es gibt eben auch Celvapan aus dem Hause Baxter. Von diesem hat die Regierung 200.000 Dosen bestellt - für die Bundeswehr, für Beamte und für Politiker.

Regierung und Hersteller versichern zwar, dass beide Mittel den gleichen medizinischen Nutzen haben. Doch Celvapan, jenes für die "Elite" , hat angeblich weniger Nebenwirkungen. Laut Innenministerium der pure Zufall. Man sei gezwungen gewesen, bei Baxter einzukaufen, da der Bund mit der Firma seit mehreren Jahren einen Liefervertrag für Impfstoffe hat.

Zwar beteuert Kanzlerin Angela Merkel, auch sie werde das "Volks-Serum" nehmen, doch die Empörung ist groß. "Dieser Vorgang ist äußert unglücklich. Es entsteht der Eindruck einer Zweiklassenmedizin" , kritisiert SPD-Gesundheitsexperte Karl Lauterbach. "Zweierlei Impfstoffe für Regierung und Bevölkerung ist das falsche Signal" , sagt auch Ulrike Mascher, Chefin des Sozialverbandes VdK.

Als naturheilkundliche Alternative bieten Ärzte übrigens auch die Paracelsus-Grippe-Prophylaxe an. Diese immunstimulierende Spritze wirkt gegen alle infektiösen Krankheiten und muss im Lauf des Winters dreimal verabreicht werden. Allerdings ist sie nicht gratis. (Birgit Baumann/Michael Simoner/DER STANDARD, Printausgabe, 20.10.2009)

THE BUDAPEST TIMES

Robert Hodgson

New treatment in Flu vvaccine controversy

The Budapest Times, 20 October 2009
https://web.archive.org/web/20091027141008/http://www.budapesttimes.hu/content/view/13267/219/

A 64-year-old woman died last week just two days after receiving an inoculation against the new A(H1N1) influenza virus dubbed swine flu. The state medical service ÁNTSZ ordered an autopsy to establish whether there was any link between the vaccine and the death of the patient, who suffered from chronic, but mild, heart disease.

New fatality

Last week also saw Hungary’s fourth fatality attributed to A(H1N1) infection. A 47-year-old man who died in hospital was found to have been infected with the virus, health minister Tamás Székely told reporters last Thursday. The patient was being treated for pneumonia.

Hungary’s chief medical officer Ferenc Falus addressed a parliamentary Health Committee last Wednesday and urged Hungarians to get themselves vaccinated as quickly as possible. Falus had himself inoculated in front of reporters in a bid to quell public fears over the safety of the vaccine. The previous week, the manufacturer of Hungary’s A(H1N1) vaccine, Omninvest, had threatened to sue media for "scaremongering” by suggesting the vaccine could be ineffective or dangerous.

Winter epidemic possible

Meanwhile, the ÁNTSZ warned that infection could reach epidemic proportions by early next year following the onset of winter weather. Fewer than 300 cases of A(H1N1) infection have been confirmed in Hungary since the virus was first detected in humans. However, the week before last, some 16,000 cases of influenza were registered nationwide, and it is likely that a good deal, if not most, of these are down to the new variant virus.

Hungary's new flu vaccine not suitable for children, pregnant women, says health advisor

The vaccine against the new flu virus is not suitable for small children and pregnant women, a member of Hungary's Collegium for Infectology, an advisor to the Health Ministry, said in a television programme on TV2 on Sunday evening.

Pregnant women should instead be treated with antiviral products, of which there is not enough in the country, Andras Szalka said.

The Health Ministry responded that it had not to date received a statement from the Collegium to this effect, however, it added that Chief Medical Officer Ferenc Falus has called a meeting of the pandemic committee for Monday, where this matter would be discussed.

The fourth patient died in Hungary on Thursday associated with the new flu A/H1N1 virus. The virus had been revealed in 283 cases since it appeared in Hungary in May.

REUTERS

Swine flu vaccines delayed, CDC says

Reuters, 20 October 2009, 6:54 PM GMT+8
https://www.reuters.com/article/us-flu-vaccine-usa/swine-flu-vaccines-delayed-cdc-says-idUSTRE59F4VV20091017/

Washington (Reuters) – Delivery of some swine flu vaccines has been delayed because companies cannot make it as fast as they had hoped, just as the virus has really started to spread, the U.S. Centers for Disease Control and Prevention said on Friday.

The CDC's Dr. Anne Schuchat said that while 40 million doses had been anticipated for the end of October, only about 28 to 30 million doses would be available.

"Yields for vaccine are lower than would be hoped," Schuchat said in a telephone briefing. "We unfortunately won't have as much at the end of this month as we had hoped to."

She also said deaths from H1N1 swine flu were above the epidemic threshold in some U.S. cities and states. H1N1 flu activity was widespread in 41 states, she said.

"It is unprecedented for this time of year to have the whole country having such high levels of activity," Schuchat said.

"There are now a total of 86 children under 18 who have died from the 2009 H1N1 influenza virus," she added. Many had died in recent weeks and the number was now higher than the usual number of child deaths in an entire flu season.

"These are very sobering statistics ... 43 deaths in one month is a lot," Schuchat said. "Some of these children have been totally healthy."

Older children were hardest hit, she said, with 16 deaths among 5- to 11-year-olds and 19 deaths in 12- to 17-year-olds.

The new virus, which emerged in March and was declared a pandemic in June, does not seem any deadlier than seasonal influenza. But it attacks a different age group – older children and young adults, unlike seasonal flu, which affects mostly elderly people and kills up to 36,000 in a normal year.

And because hardly anyone has immunity, the H1N1 virus may infect far more people than seasonal flu does in a single season.

Bumpy Delivery

Schuchat said 15 percent to 20 percent of patients with H1N1 who needed to be hospitalized were requiring intensive care. "Influenza is widespread in the country and illnesses, hospitalizations and deaths continue to increase," she said.

The U.S. government has opted to roll out seasonal flu vaccine and H1N1 vaccines as they become available, which the CDC has said could make for a bumpy vaccination plan.

People need both vaccines to be protected from all the circulating viruses, although Schuchat says virtually all cases of influenza are due to the new H1N1 virus.

As of Wednesday, 11.4 million doses of H1N1 vaccine were available and 8 million had been ordered by states for distribution.

The U.S. government has ordered both types of flu vaccine from five companies: Sanofi-Aventis SA, CSL Ltd, Novartis AG, GlaxoSmithKline and AstraZeneca unit MedImmune.

Schuchat said 82 million doses of seasonal flu vaccine had been distributed, with a total of 114 million doses ordered. On Thursday CVS Caremark Corp said it would cut short its flu-shot clinics due to delivery delays.

"This is how influenza vaccine production often goes," Schuchat said. She said there should be widespread availability by November and advised people who wanted a vaccine but were having trouble finding one to keep trying.

The Washington Times

Ann Geracimos

Study: H1N1 vaccine too late to help most

The Washington Times, 20 October 2009
https://www.washingtontimes.com/news/2009/oct/20/study-swine-flu-vaccine-too-late-to-help-most/

The H1N1 vaccine will arrive too late to help most Americans who will be infected during this flu season, according to a study conducted by scholars at Purdue University.

The study also estimates that the virus – commonly referred to as the swine flu bug – will infect about 60 percent of the U.S. population, although only about 25 percent of Americans will fall ill.

Published Oct. 15 in Eurosurveillance, a scientific journal devoted to epidemiology and the surveillance and control of communicable diseases, the study was conducted by professors Sherry Towers and Zhilan Feng of, respectively, Purdue's statistics and mathematics departments.

"The model predicts that there will be a significant wave in autumn, with 63% of the population being infected, and that this wave will peak so early that the planned [U.S. Centers for Disease Control and Prevention] vaccination campaign will likely not have a large effect on the total number of people ultimately infected by the pandemic H1N1 influenza virus," the authors wrote in their study.

The authors said that this is the week, through Oct. 24, during which the greatest number of people would be infected. The vaccination program has barely started in the U.S.

"The model predicts that the peak wave of infection will occur near the end of October in week 42, with 8% of the population being infected during that week. By the end of 2009, the model predicts that a total of 63% of the population will have been infected," the authors wrote in a conclusion that ignored the effects of a CDC vaccination program.

But even "when the model was modified to include the effect of the planned vaccination scheme," that adjustment yielded only "a relative reduction of about 6% in the total number of people infected" by the end of the year 2009.

Ms. Towers cautioned in a phone interview with The Washington Times that while enough of the U.S. population probably won't get enough of the vaccine before or during the peak of the pandemic, that is no reason not to get protection.

"Based on our study alone it would be bad to discourage people from getting the vaccine, because what if our study is wrong," she said.

She called some comments in the press "a lot of hysteria. In reality, the overwhelming majority of people getting sick are going to have a mild illness."

The study cautioned that while a majority of the U.S. population would become infected by the virus, previous studies "showed that up to 60% of seasonal influenza infections are asymptomatic." That is, people became infected but showed no symptoms.

"If the same is true of the current pandemic influenza, about a quarter of the population will fall ill," the authors wrote.

Canada is in a much more dire straits on vaccination, Ms. Towers noted in her interview, because of relative slowness of the country's equivalent of the Food and Drug Administration (FDA) to approve the vaccine.

"They are more cautious and conservative and sitting on at least 1 million doses waiting for delivery. They won't begin vaccination until the first week of November," she said.

However, the study, which used data only though the week ending Aug. 22, assumed that "the planned CDC vaccination program against pandemic H1N1 influenza will begin with six to seven million doses being delivered by the end of the first full week in October."

That assumption turned out to be more optimistic about the program's numbers than turned out to be case – about 6.8 million doses were available and 3.7 million doses had been ordered, the CDC said on Oct. 9.

Shipments reported Friday were down by a quarter, because of a slowdown in production caused by difficulties of processing great numbers.

The study also assumed that all adults would achieve full immunity shortly after receiving inoculations and assumed that children and adults are equally responsive to the flu vaccine. Both assumptions are medically dubious, though hard to compensate for statistically.

All these statistical assumptions and prediction errors would lead the study to underestimate the number of infections.

The study was based on a statistical analysis of weekly reports from the CDC for a model derived from the observed spread of the H1N1 virus "during summer 2009 to predict the behavior of the pandemic during autumn 2009."

A White House scenario released in late August by a group of presidential advisers had predicted that anywhere from 30 percent to 50 percent of the population would get the novel virus strain, and an estimate on the number of deaths ranged from 30,000 to 90,000. The regular seasonal flu normally affects up to 20 percent of the population, with 36,000 deaths resulting.

Dr. Thomas Frieden, CDC director, cautioned at the time that such a prognosis was unlikely unless the virus changed and mutated into another form, which, to date, has not happened. Further estimates and availability of vaccine doses are due from CDC officials Tuesday.

But the Purdue scholars' study predicts a higher rate of infection and illness than previous projections because, the authors explained to The Washington Times in separate e-mails, they used a better formula - "a seasonally forced SIR model" that adjusts the rates of infection spread for the different times of the year.

"However, one aspect of influenza that needs to be added to the [SIR] model is its seasonal nature; it is more infectious in the fall and winter in the northern hemisphere than it is in the summer. We refer to this as 'seasonal forcing.' … Our model takes this seasonal forcing into account," Ms. Towers wrote.

THE IRISH TIMES

Concern in Germany as safety of swine flu vaccines questioned

The Irish Times, 20 October 2009, 01:00
https://www.irishtimes.com/news/concern-in-germany-as-safety-of-swine-flu-vaccines-questioned-1.759250

Germany's swine flu vaccination programme has been hit by public health concerns over the vaccines being used – one of which has been ordered by the Irish Government.

Germany's 16 federal states have spent a reported €600 million buying 50 million doses of the Pandemrix vaccine, produced by GlaxoSmithKline (GSK).

This new vaccine, one of two to be offered by Irish doctors, is the subject of controversy in Germany because it contains a "booster" substance known as an "adjuvant". This allows less virus material to be used per dose and, according to GSK, boosts the immune system's response to the jab.

Pandemrix was approved for use by the European Medicines Agency last month and has the approval of Germany's Paul Ehrlich Institute, which advises the government on vaccination matters. However, another government body, the Federal Vaccination Agency, has contradicted the institute and has advised against the use of vaccines containing adjuvants.

Concerns about Pandemrix's safety and efficacy have been raised by several German medical organisations, with warnings against using it to vaccinate high-risk groups such as pregnant women and children.

Dr Wolfram Hartmann, president of the German association of paediatricians, accused the federal government of "false testimony" for recommending Pandemrix for use on young children – six weeks after it issued advice to the contrary. – "The vaccine has not yet been tested on children under three, so the risk is simply too big to use on them without misgivings," he said.

The vaccine confusion grew over the weekend when it emerged that the German government and armed forces are to receive a different jab to the public. Celvapan, produced by drug company Baxter, is a traditional vaccine containing no booster substances.

The interior ministry in Berlin denied yesterday it was a case of two-tier medical care. A spokes-person said the federal government had a contract to buy Baxter flu vaccination products for state employees.

The Health Service Executive (HSE), now delivering the GSK vaccine to GPs and awaiting supplies of the Baxter one, said the safety data base for the GSK adjuvant includes more than 10,000 individuals.

"As with any vaccines, risks have to be balanced with the benefits and the authorities in Ireland are satisfied that the benefits from both vaccines outweigh any possible risks of side effects." The HSE said Ireland continues to see an increase in swine flu cases every week as well as fatalities associated with this virus. The fifth fatality was confirmed last night. The deceased, an adult male in the east, had an underlying medical condition. – "Vaccination is the most important tool we have to protect the Irish population," the HSE said.

Stirring things up even further in Germany yesterday, outgoing interior minister Wolfgang Schäuble said: "I'm not even sure if I will be getting vaccinated at all."

In an attempt to calm the situation, Chancellor Angela Merkel's spokesman said the German leader, if so advised by her doctor, would be vaccinated with Pandemrix.

Hamburger Abendblatt

Massenimpfung droht ein Millionen-Flop zu werden

Hamburger Abendblatt, 20 October 2009, 06:00 Uhr
https://www.abendblatt.de/politik/deutschland/article107577297/Massenimpfung-droht-ein-Millionen-Flop-zu-werden.html

Der Wirbel um eine angebliche Bevorzugung von Politikern bei der Schweinegrippe-Impfung wird laut Experten Folgen haben.

Berlin. Die Bundesregierung hat Vorwürfe zurückgewiesen, sie sichere sich bei der Schweinegrippe-Impfung die Versorgung mit einem besseren Impfstoff. Regierungssprecher Ulrich Wilhelm sagte, Meldungen, wonach für Politiker der Bundesregierung ein Sonderimpfstoff bestellt worden sei und es eine Zwei-Klassen-Versorgung gebe, entbehrten jeder Grundlage.

Richtig sei, dass die Bundesverwaltung bereits im vergangenen Jahr für Teile ihrer Angehörigen wie Soldaten, Bundespolizei und die fast 70.000 Mitarbeiter der Krisenstäbe einen eigenen Vertrag mit dem US-Hersteller Baxter abgeschlossen habe. Der Impfstoff Celvapan des Herstellers Baxter enthält im Gegensatz zum Mittel Pandemrix, das die Länder für die Bevölkerung bestellt haben, keinen Wirkverstärker und gilt deshalb als verträglicher.

Wilhelm betonte, es gebe "keinen besseren oder schlechteren Impfstoff". Alle zugelassenen Impfstoffe gegen die Schweinegrippe hätten die Kriterien erfüllt, die an "Wirksamkeit, Qualität und Unbedenklichkeit gestellt werden". Laut einem Bericht der "Bild"-Zeitung setzt Bundeskanzlerin Angela Merkel (CDU) trotz des für die Bundesregierung bestellten Impfstoffes auf ihren Hausarzt, von dem sie den Massen-Impfstoff Pandemrix bekommen soll.

Der Hallenser Virologe Alexander Kekulé befürchtet durch die nun entbrannte Debatte um zweierlei Impfstoffe für Bundesverwaltung und Bevölkerung, dass viele bislang unentschlossene Menschen aus Verunsicherung gar nicht mehr zur Impfung gehen wollen. "Und das ist eigentlich der höchste Preis, den wir zahlen können, wenn wir nämlich nicht mehr diese Chance haben, diese Pandemie durch eine allgemeine Impfung zu beenden", sagte Kekulé im NDR. Der Virologe hatte den Impfstoff Pandemrix wegen seiner Nebenwirkungen zuvor selbst heftig kritisiert.

Der Vorstandschef der Barmer Ersatzkasse, Johannes Vöcking, sagte, dass die gesetzlichen Kassen finanzielle Rückforderungen an die Länder stellen würden, wenn der georderte Impfstoff nicht verbraucht werde und sich nicht weiter verkaufen lasse. Die Kassen müssen die Kosten für die Immunisierung von 50 Prozent ihrer Versicherten tragen und haben dafür bereits 600 Millionen Euro vorgeschossen. Insgesamt kosten die bestellten 50 Millionen Dosen rund eine Milliarde Euro.

Am kommenden Montag läuft die freiwillige Massenimpfung gegen die Schweinegrippe in Deutschland an. Seit gestern wird der Impfstoff ausgeliefert. In der ersten Woche können sich zunächst allerdings nur Angehörige des sogenannten Schlüsselpersonals impfen lassen. Dabei handelt es sich um Beschäftigte in Gesundheitswesen und Wohlfahrtspflege, bei Polizei und Feuerwehr.

In der folgenden Woche, also ab 2. November, sind sogenannte medizinische Risikogruppen an der Reihe. Darunter versteht man Erkrankte beispielsweise mit schweren Atemwegsinfektionen oder Immunschwäche, die an der Schweinegrippe sterben könnten. Ab Mitte November kann sich dann jeder Interessierte impfen lassen. Zu diesem Zeitpunkt wird auch entschieden sein, ob zwei Impfdosen im Abstand von mehreren Wochen nötig sind, oder für Erwachsene unter 60 auch eine Dosis ausreicht.

SOS JUSTICE & DROITS DE L'HOMME

GrippeA/H1N1: Les vaccins en Zone défense, Loi martiale?

Dossiers SOS Justice, 20 Oktobre 2009.
https://web.archive.org/web/20091022172445/http://dossiers-sosjustice.hautetfort.com/archive/2009/10/20/grippea-h1n1-les-vaccins-en-zone-defense-loi-martiale.html

La campagne de vaccination contre le virus de la grippe H1N1 commence Mardi 20 Octobre 2009 pour le personnel hospitalier prioritaire, vacciné sur son lieu de travail, et "après les vacances de la Toussaint" pour les autres, a annoncé Lundi 19 Octobre le ministère de la Santé (1).

Les opérations de vaccination sont organisées en ZONES DE DÉFENSE sur le mode d'activation du dispositif ORSEC et le préfet prend la direction des opérations de secours (DOS).

A ce sujet, le Journal nice-matin du Vendredi 16 Octobre 2009 précise: Les vaccins en Zone de défense (2).

La France est sectorialisée en 7 *zones de défense* (Bordeaux, Lille, Lyon, Marseille, Metz, Paris et Rennes).

Un préfet délégué à la sécurité et à la défense, assisté d'un chef d'Etat Major, est nommé auprès du préfet de zone pour assurer la direction de l'Etat Major de Zone, du service de zone des systèmes d'information et de communication et du secrétariat général pour l'administration de la police (3).

Aussi, le Journal nice-matin du Vendredi 16 Octobre 2009 indique que les écoliers et la communauté éducative seront directement vacciner dans les établissements scolaires sans convocation. Nos enfants seront soumis à une vaccination *obligatoire*.

En plus, toujours d'après le Journal nice-matin du Vendredi 16 Octobre 2009, le dispositif peut être amené à évoluer. Il faut savoir que la mise en place des *zones de défense* permettent, avec l'Alerte de Niveau 6 et les directives de l'OMS, la Militarisation du territoire national et l'établissement d'un Véritable État d'exception.

A ce sujet, la circulaire du Préfet de la Marne du 12 Février 2006 concernant l'Action des maires dans la gestion d'une crise sanitaire majeure de type « pandémie grippale» est trés contraignante pour la population (4):
- la fermeture ou le contrôle des frontières
- l'arrêt des transports publics de passagers
- la restriction des déplacements (déplacements individuels, isolements, cordons sanitaires..)
- la suspension des rassemblements de population
- la fermeture des établissements scolaires et des crèches
- la limitation de toutes les manifestations (spectacles, rencontres sportives, foires et salons, (etc)

Aussi et pour information, les "Opérations funéraires" de cette même circulaire insiste sur:
- l'identification des sites pouvant recevoir des corps sans mise en bière (fosses communes)
- le recensement des sites de stockage de cercueils
- la réalisation d'un annuaire avec les coordonnées des entreprises de pompes funèbres

Une autre circulaire, plus récente, du 10 septembre 2009, adressée aux personnels civils et militaires de la gendarmerie nationale indique que les familles des personnels, comme les autres citoyens, seront convoquées pour la vaccinations (5).

Cependant, en Alerte Niveau 6, l'OMS peut prendre le Contrôle de la situation sanitaire avec les 7 *zones de défense* en France et peut imposer, suivant les cas, des mises en quarantaine et sûrement la vaccination forcée.

De plus, une Justice d'exception peut être mise en place.

Enfin, concernant la vaccination forcée et d'après le témoignage d'un ancien directeur du CNRS, M. JP Petit, les militaires français stationnés dans les territoires et département des DOM-TOM auraient reçu l'ordre de se préparer aux vaccinations forcées et aux arrestations de manifestants (6).

THE FLU CASE

Threat of martial law in France looms as "swine flu" jab campaign starts

The Flu Case, 21 October 2009, 12:31

https://web.archive.org/web/20091025043116/http://www.theflucase.com/index.php?option=com_content&view=article&id=1256:threat-of-martial-law-in-france-looms-as-qswine-fluq-jab-campaign-starts&catid=41:highlighted-news&Itemid=105&lang=en

Fears of the threat of martial law being implemented in the coming weeks in France are growing after the start of the mass "swine flu" vaccination campaign yesterday.

French group SOS Justice says that the organisation of the "swine flu" vaccination campaign has been shaped to increase the chances of the successful implementation of military rule.

The mass "swine flu" vaccination operation has been organised to fit the country's seven defence zones, set up to allow martial law to be imposed swiftly in the event of a national emergency such as a pandemic.

The zones – similar to the FEMA regions in the USA -- are Bordeaux, Lille, Lyon, Marseille, Metz, Paris and Rennes.

A document from 2006, says that the military will be able to close borders, shut down schools and stop public assemblies among other martial law style measures in the event of a national emergency such as a pandemic.

Furthermore, the same document contained plans for dealing with mass fatalities, specifically, the need to identify mass graves.

A former director of CNRS, J-P Petit has said that the French army belonging to overseas territories (DOM-TOM) has been told to prepare for mass forced vaccinations and to arrest protestors.

A French government document dated September 10th outlined plans for the compulsory vaccination of every single member of France's Gendamerie, a 100,000-strong military force charged with policing more rural parts of France.

The documents also foresaw the vaccination of all family members of the Gendamerie.

A report in Nice Matin dated October 16th indicated that the department Alpes Maritimes was planning to give the "swine flu" jab to every child at school without asking for parent's permission.

In the event of a pandemic level 6 emergency being declared by WHO – as happened in June – WHO is able to activate provisions in the International Health Regulations 2005 and the national pandemic plan in order to exercise authority over all public health and law enforcement services.

WHO is entitled to employ these "assets" to conduct forced quarantines and vaccinations.

Nurses to administer swine flu vaccine as GPs opt out

Irish Independent, 21 October 2009 at 12:00
https://www.independent.ie/life/health-wellbeing/nurses-to-administer-swine-flu-vaccine-as-gps-opt-out/26575289.html

Public health nurses may have to be drafted in to give the swine flu vaccine in some parts of the country. The nurses will also be used in Dublin because of a lack of GPs willing to take part in the scheme, it was learned last night.

The news came as health officials here insisted the vaccine is safe after fears were voiced in Germany about it.

It is understood that public health nurses in parts of north Dublin may have to give at-risk patients the jab instead of GPs who are have refused to sign up due to uncertainty over their indemnity cover.

According to the Health Service Executive (HSE), over 150 more GPs have signed up on top of the existing 1,800 who had indicated their intention to give the vaccine to at-risk patients.

The vaccine is being distributed to GPs taking part in the scheme over the next month and full-scale clinics are expected to be provided by doctors in the next fortnight.

It emerged on Monday that some GPs who had not indicated their willingness to take part in the vaccination had received vaccine. The HSE spokesman said that around 12 GPs who received the vaccine contacted the HSE saying they did not want it. The supplies are to be collected by the company distributing the doses.

Meanwhile, chief medical officer Dr Tony Holohan yesterday insisted the vaccine was safe despite fears expressed by medics in Germany.

The German controversy arose after it emerged that the Pandemrix vaccine, made by Glaxosmithcline, was being given to the general public, while the Baxter vaccine is to be administered to the German government and armed forces.

The Pandemrix vaccine is currently being distributed to GPs in this country although supplies of the Baxter vaccine are also due.

Dr Holohan said the Pandemrix vaccine contains an adjuvant to boost the immune system's response and the Baxter vaccine does not have this ingredient.

Safety

However, he said the adjuvants were used in other vaccines also and they had been tested in safety trials. He added: "We are quite happy that this vaccine, as with all other influenza vaccines, has a very good safety profile."

Both vaccines have been licensed by the European Medicines Agency and the Irish Medicines Board.

Children will need two jabs of Pandemrix spaced three weeks apart, because their immune systems do not respond as well as adults.

Five people have died from swine flu in Ireland, the latest being a man who passed away on Sunday. He had an underlying illness, as had the other victims.

Swine Flu Cases Overestimated?
CBS News Exclusive: Study of State Results Finds H1N1 not as Prevalent as Feared

CBS News, 21 October 2009
https://web.archive.org/web/20091022182003/http://www.cbsnews.com/stories/2009/10/21/cbsnews_investigates/main5404829.shtml

(CBS) If you've been diagnosed "probable" or "presumed" 2009 H1N1 or "swine flu" in recent months, you may be surprised to know this: odds are you didn't have H1N1 flu.

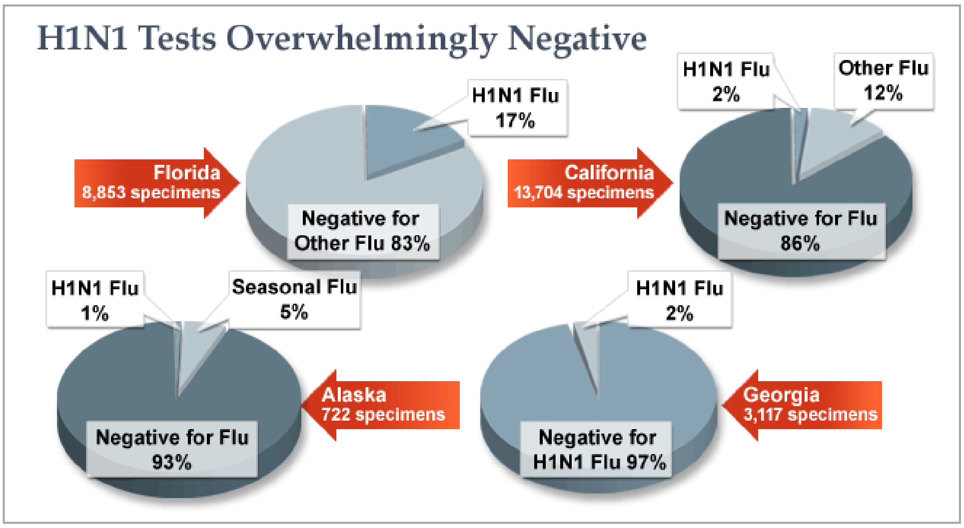
In fact, you probably didn't have flu at all. That's according to state-by-state test results obtained in a three-month-long CBS News investigation.

The ramifications of this finding are important. According to the Centers for Disease Control and Prevention (CDC) and Britain's National Health Service, once you have H1N1 flu, you're immune from future outbreaks of the same virus. Those who think they've had H1N1 flu – but haven't – might mistakenly presume they're immune. As a result, they might skip taking a vaccine that could help them, and expose themselves to others with H1N1 flu under the mistaken belief they won't catch it. Parents might not keep sick children home from school, mistakenly believing they've already had H1N1 flu.

Why the uncertainty about who has and who hasn't had H1N1 flu?

In late July, the CDC abruptly advised states to stop testing for H1N1 flu, and stopped counting individual cases. The rationale given for the CDC guidance to forego testing and tracking individual cases was: why waste resources testing for H1N1 flu when the government has already confirmed there's an epidemic?

Some public health officials privately disagreed with the decision to stop testing and counting, telling CBS News that continued tracking of this new and possibly changing virus was important because H1N1 has a different epidemiology, affects younger people more than seasonal flu and has been shown to have a higher case fatality rate than other flu virus strains.



CBS News learned that the decision to stop counting H1N1 flu cases was made so hastily that states weren't given the opportunity to provide input. Instead, on July 24, the Council for State and Territorial Epidemiologists, CSTE, issued the following notice to state public health officials on behalf of the CDC:

"**Attached are the Q&As**; that will be posted on the CDC website tomorrow explaining why CDC is no longer reporting case counts for novel H1N1. CDC would have liked to have run these by you for input but unfortunately there was not enough time before these needed to be posted

When CDC did not provide us with the material, we filed a Freedom of Information request with the Department of Health and Human Services (HHS). More than two months later, the request has not been fulfilled. We also asked CDC for state-by-state test results prior to halting of testing and tracking, but CDC was again, initially, unresponsive.

Watch CBS News Videos Online –
Video above: A CBS News producer asks the director of the CDC, Dr. Thomas Frieden, for this information at a press conference on Sept. 19.

While we waited for CDC to provide the data, which it eventually did, we asked all 50 states for their statistics on state lab-confirmed H1N1 prior to the halt of individual testing and counting in July. The results reveal a pattern that surprised a number of health care professionals we consulted. The vast majority of cases were negative for H1N1 as well as seasonal flu, despite the fact that many states were specifically testing patients deemed to be most likely to have H1N1 flu, based on symptoms and risk factors, such as travel to Mexico.

It's unknown what patients who tested negative for flu were actually afflicted with since the illness was not otherwise determined. Health experts say it's assumed the patients had some sort of cold or upper respiratory infection that is just not influenza.

With most cases diagnosed solely on symptoms and risk factors, the H1N1 flu epidemic may seem worse than it is. For example, on Sept. 22, this alarming headline came from Georgetown University in Washington D.C.: "H1N1 Flu Infects Over 250 Georgetown Students."

H1N1 flu can be deadly and an outbreak of 250 students would be an especially troubling cluster. However, the number of sick students came not from lab-confirmed tests but from "estimates" made by counting "students who went to the Student Health Center with flu symptoms, students who called the H1N1 hotline or the Health Center's doctor-on-call, and students who went to the hospital's emergency room."

Without lab testing, it's impossible to know how many of the students actually had H1N1 flu. But the statistical trend indicates it was likely much fewer than 250.

CDC continues to monitor flu in general and H1N1 through "sentinels," which basically act as spot-checks to detect trends around the nation. But at least one state, California, has found value in tracking H1N1 flu in greater detail.

"What we are doing is much more detailed and expensive than what CDC wants," said Dr. Bela Matyas, California's Acting Chief of Emergency Preparedness and Response. "We're gathering data better to answer how severe is the illness. With CDC's fallback position, there are so many uncertainties with who's being counted, it's hard to know how much we're seeing is due to H1N1 flu rather than a mix of influenza diseases generally. We can tell that apart but they can't."

After our conversation with Dr. Matyas, public affairs officials with the California Department of Public Health emphasized to CBS News that they support CDC policy to stop counting individual cases, maintaining that the state has the resources to gather more specific testing data than the CDC.

Because of the uncertainties, the CDC advises even those who were told they had H1N1 to get vaccinated unless they had lab confirmation. "Persons who are uncertain about how they were diagnosed should get the 2009 H1N1 vaccine."

That's unwelcome news for a Marietta, Georgia mom whose two children were diagnosed with "probable" H1N1 flu over the summer. She hoped that would mean they wouldn't need the hastily developed H1N1 flu vaccine. However, since their cases were never confirmed with lab tests, the CDC advises they get the vaccine. "I wish they had tested and that I knew for sure whether they had it. I'm not anxious to give them an experimental vaccine if they don't need it."

Speaking to CBS' "60 Minutes," CDC Director Dr. Frieden said he has confidence that the vaccine will be safe and effective: "We're confident it will be effective we have every reason to believe that it will be safe."

However, the CDC recommendation for those who had "probable" or "presumed" H1N1 flu to go ahead and get vaccinated anyway means the relatively small proportion of those who actually did have H1N1 flu will be getting the vaccine unnecessarily. This exposes them to rare but significant side effects, such as paralysis from Guillain-Barre syndrome.

It also uses up vaccine, which is said to be in short supply. The CDC was hoping to have shipped 40 million doses by the end of October, but only about 30 million doses will be available this month.

The Guardian

Swine flu mass vaccination programme launched
11m priority patients and frontline health workers offered jab in first phase

The Guardian, 21 October 2009, 14:52 BST
https://www.theguardian.com/world/2009/oct/21/swine-flu-mass-vaccination

The UK's mass vaccination programme against swine flu was launched today, targeting 11 million priority patients and frontline health workers in its initial phase.

Amid fears that there would be a low take-up among NHS staff, the prime minister, Gordon Brown, told the Commons that the country was "ahead of the world" in its fight against the potentially fatal infection.

Doses of the drug Pandemrix are being offered in hospitals from today and supplies are being delivered to GPs' surgeries from the beginning of next week. Medical officials fear that a post office strike could delay letters being sent out to patients calling them in for immunisation.

The health secretary, Andy Burnham, was at University College Hospital in London for the first vaccinations. He said: "The people today who are volunteering are showing real leadership, they are sending a clear message out to people working in the health service that it is the right thing to do."

"We are one of the first countries in the world to launch a vaccination programme and we are looking ahead to a very difficult winter in the NHS, there is still seasonal flu around and we have the added challenge of H1N1 swine flu."

Sir Liam Donaldson, the chief medical officer for England, said: "This is the first pandemic for which we have had vaccine to protect people. I urge everyone in the priority groups to have the vaccine - it will help prevent people in clinical risk groups from getting swine flu and the complications that may arise from it. It's important for frontline health and social care workers to have the vaccine.

"It will help prevent them and their families getting the virus from patients, it will stop them passing the virus on to their patients, it will potentially protect them from mutated strains and it will reduce the disruption to NHS services caused by people being absent due to illness."

NHS staff have traditionally been reluctant to participate in mass immunisations. Only around 20% normally receive the seasonal flu vaccination. In a bid to overcome suspicions, professional health organisations urged their members to be innoculated.

A joint statement was issued by the British Medical Association, the Royal College of GPs, Royal College of Midwives, Royal College of Nursing, Royal College of Psychiatrists, Royal College of Obstetricians and Gynaecologists and Royal Pharmaceutical Society of Great Britain, as well as the union Unison which represnets many health workers.

It declared: "By the nature of their work, many NHS staff come into close contact with patients and the public and have a higher risk of exposure to the virus."

"The vaccine has been thoroughly tested. All NHS organisations will be working hard to ensure that eligible staff are given access to the vaccination to protect themselves, their families and their patients from swine flu. We encourage staff to protect themselves with the swine flu vaccine, in addition to the seasonal flu immunisation."

The UK death toll from the H1N1 virus has risen to 108 so far, with more than 70 people being treated in intensive care wards around the country. The age profile of those succumbing to serious infections is different to normal seasonal flu. As many as 370,000 people are estimated to have contracted the virus so far in the UK.

Victims of swine flu have tended to be far younger. Pregnant women are recognised as being particularly at risk; six of the UK deaths have been of women in the later stages of pregnancy.

In west Wales, a primary school was closed following high levels of staff sickness. Pontyberem community primary school in Carmarthenshire is due to reopen after the half-term holiday.

It is no longer routine policy to close schools if individuals catch the virus. At the last weekly briefing, the chief medical officer, Sir Liam Donaldson, revealed that almost 150 schools had recorded outbreaks.

Swine flu vaccination gets underway in Europe

Reuters, 21 October 2009, 7:48//7:50 PM

https://www.reuters.com/article/governmentFilingsNews/idUSLL4304520091021?sp=true
https://web.archive.org/web/20091027172042/http://www.reuters.com/article/governmentFilingsNews/idUSLL4304520091021?sp=true

Oct 21 (Reuters) - European governments are starting to roll out mass vaccination programmes against H1N1 swine flu, with Britain the latest country to begin immunisation on Wednesday.

The European Medicines Agency has approved three H1N1 vaccines – GlaxoSmithKline's (GSK.L) Pandemrix, Novartis's (NOVN.VX) Focetria and Baxter International's (BAX.N) Celvapan – and others may yet be added to this list.

There have been a total of 230 deaths linked to H1N1 in Europe since April, with nearly half of them occurring in Britain, according to the Stockholm-based European Centre for Disease Prevention and Control.

Outside Europe, vaccination programmes are also underway in various countries, including the United States, China and Australia.

Here is a snapshot of vaccination plans in selected European countries:

BRITAIN
Nationwide vaccination programme launched on Oct. 21, starting with front-line health workers and hospital patients deemed to be at high risk. Family doctors will start immunising patients in priority groups from Oct. 26.

FRANCE
Vaccinations began on Oct. 20 for hospital staff. Shots will be offered to the general population starting from the first week in November.

GERMANY
Regional states will start a programme of vaccination on Oct. 26. The initial focus will be on healthcare workers, police and fire-fighters, plus people in at-risk groups and pregnant women.

ITALY
Doctors began H1N1 vaccinations on Oct. 14.

SWEDEN
First vaccinations were carried out on Oct. 12.

SPAIN
Vaccinations are expected to start in the second half of November.

NETHERLANDS
Officials expect to start vaccination of at-risk groups in the week starting Nov. 9.

IRELAND
A national vaccination programme will begin on Nov. 2.

SWITZERLAND
H1N1 vaccines still need to be approved by the country's own regulatory agency and immunisation is not expected to start until around the end of this month or the start of November.

CBC news

Antiquated Process Delays H1N1 Vaccines

CBC News, 21 October 2009, 9:00 PM EDT / AP
https://www.cbsnews.com/news/antiquated-process-delays-h1n1-vaccines/

The U.S. federal government originally promised 120 million doses of swine flu vaccine by now. Only 13 million have come through.

As nervous Americans clamor for the vaccine, production is running several weeks behind schedule, and health officials blame the pressure on pharmaceutical companies to crank it out along with the ordinary flu vaccine, and a slow and antiquated process that relies on millions of chicken eggs.

There have been other bottlenecks, too: Factories that put the precious liquid into syringes have become backed up. And the government itself ran into a delay in developing the tests required to assess each batch before it is cleared for use.

Special Report: H1N1 Virus

What effect the delays will have on the course of the outbreak is unclear, in part because scientists cannot say with any certainty just how dangerous the virus is, how easily it spreads, or whether it will mutate into a more lethal form.

"We're in this race against the virus, and only Mother Nature knows how many cases are going to occur over the next six to 10 weeks," said Michael Osterholm, a vaccine expert at the University of Minnesota.

In the meantime, many U.S. states have had to postpone mass vaccinations. Clinics around the country that managed to obtain doses of the vaccine have been swamped. And doctors are getting bombarded with calls from worried and angry parents.

"Nobody has it," said AnnMarie O'Connor, who waited more than four hours for the vaccine in Rockville, Maryland, standing in line with her two young children and about 1,000 other people. Health officials "said the shots would be here in early October. But where are they?"

Federal officials counsel patience, saying that eventually there should be enough of both vaccines for everyone who wants them.

"We wish we had better ways to produce vaccines perfectly predictably, but this is how influenza vaccine production often goes," Dr. Anne Schuchat, who heads the immunization and respiratory disease section at the Centers for Disease Control and Prevention, said last week.

The delays have led to renewed demands for a quicker, more reliable way of producing vaccines than the chicken-egg method, which is 50-year-old technology and involves injecting the virus into eggs and allowing it to feed on the nutrients in the egg white.

Since April, swine flu has killed more than 800 people in the U.S., including 86 children.

Federal health officials initially projected that as many as 120 million doses of the vaccine would be ready to dispense by mid-October. They later reduced their estimate to 45 million. As of Tuesday, only 12.8 million were available.

In a sign of how rapidly the virus is spreading, education officials said 198 schools in 15 states were closed Wednesday because of swine flu, with more than 65,000 students affected. That was up from 88 school closings the day before.

"Right now, the vaccine is in a race against the virus, and the virus is winning," Osterholm said.

The government now hopes to have about 50 million doses out by mid-November and 150 million in December, Dr. Nicole Lurie, assistant health and human services secretary for preparedness, told The Associated Press on Wednesday. – "By the end of November, I think we're going to be pretty well back on track," she said.

However, a study by Purdue University researchers said the vaccinations will probably come too late to significantly reduce the number of infections. The study, published last week, predicted that infections would peak in late October and that by the end of the year, 63 percent of the U.S. population will have caught the virus.

The blame for the delays has been placed in part on the chicken-egg technology. It is a slow process, and the pressure on manufacturers to produce two vaccines at the same time – for both swine flu and ordinary flu – has made it even slower.

Also, the virus on which the swine flu vaccine is based was found to reproduce very slowly in eggs – much more slowly than the ordinary flu virus. Health and Human Services Secretary Kathleen Sebelius, who on Wednesday was grilled about the delays by the Senate Homeland Security Committee, said the problem has been fixed.

The U.S. government is funding newer technologies that hold the promise of a more reliable and expandable vaccine supply. – "We need a man-to-the-moon effort for flu vaccine if we don't want to find ourselves in the same position in the future," Osterholm said.

Flu vaccines are not nearly as profitable as other kinds of drugs, and most of the biggest vaccine makers have little incentive to switch from a method with which they are familiar.

At its two plants in the Pocono Mountains town of Swiftwater, Sanofi Pasteur, the top U.S. supplier of seasonal vaccine, is churning out more than 75 million doses of swine flu vaccine and 50 million doses of the winter flu variety.

Sanofi spokeswoman Donna Cary said egg-based production of flu vaccine is "tried and true" and will probably remain the dominant method for years to come. – "If it weren't for the egg-based process, we wouldn't be able to respond to this pandemic," she said.

More than 30 farms in the eastern United States are under long-term contract to provide eggs for vaccines, tending 9 million to 12 million chickens.

Once the fertilized eggs arrive at the vaccine plant, the flu virus is injected into them and allowed to multiply for several days. Then the eggshells are cracked; the virus-laden fluid is extracted, the flu virus is killed and the substance is purified. The inactivated strain is tested to determine purity, potency and yield.

From start to finish, the process takes about six months. In normal years, that is usually enough time to get the vaccine to anyone who wants it. But in an all-out epidemic, egg-based production is incapable of producing huge batches quickly.

The government has awarded a $487 million contract to Novartis for a plant in North Carolina that will make flu vaccine by growing the virus inside animal cells, preferably from mammals. The plant is expected to be up and running by 2011 or 2012.

Also, Protein Sciences Corp. of Meriden, Connecticut, landed a five-year, $147 million contract to develop a vaccine using its recombinant technology – flu proteins grown in insect cells. The hope is that the first doses would be available within 12 weeks of the beginning of a pandemic. That is about twice as fast as flu vaccine produced from eggs. – "I think you're going to see these new technologies come on board rapidly, especially given what's happened this year," said Paul Radspinner, president and chief executive of FluGen Inc., a Madison, Wisconsin, company working on several new vaccine technologies of its own.

THE FLU CASE

Baxter in Austria rolls out "swine flu" jab at night in secret operation

The Flu Case, 21 October 2009

https://web.archive.org/web/20091025115216/http://www.theflucase.com/index.php?option=com_content&view=article&id=1251%3Abaxter-in-austria-rolls-out-qswine-fluq-jab-at-night-in-secret-operation&catid=41%3Ahighlighted-news&Itemid=105&lang=en

It happened in the middle of the night, yesterday, on Tuesday October 20th.

The security guard gave a signal and the barrier guarding Baxter's facilities surrounded by dense forests at Orth an der Donau was finally raised. Engines roared. Tyres screeched. Headlights flashed. Trucks carrying 500,000 doses of Baxter's "swine flu" jab Celvapan trundled past the barrier under the watchful eyes of security staff and police, and drove across the neon lit carpark.

Escorted by police vehicles, the trucks made their way down the icy country lane in the darkness. Reaching the motorway circling Vienna, the convoy split: some trucks headed to Salzburg, Voralburg and Tirol; othes headed south to Burgenland and Carinthia while still others headed north to Upper Austria.

Each palette in every lorry contained 240 boxes; each box in turn was packed with 20 vials of Celvapan; each of these 20 vials contained 10 doses of the toxic "swine flu" jab as the biggest ever mass vaccination campaign in the country's history got under way.

Baxter and government officials refused to reveal the destination of the vaccine material. The location at which the "swine flu" jabs are to be stored until they are distributed to "vaccine centers" and hospitals is to be kept top secret, according to the newspaper Österreich.

"Swine flu" jabs such as GlaxoSmithKline's Pandemrix are classified as bioweapons by EU and US regulators and they, therefore, have to be transported using especially tight security in conformity to EU and US rules on the transport of bioweapons.

These extra security precuations were very much evident in Austria as Baxter finally rolled out its Celvapan "swine flu" jab.

However, comparable security precuations were completely absent when 72 kilos of vaccine material contaminated with the live bird flu virus left Baxter's facilities in Orth an der Donau this January to be transported to a lab in Vienna called Avir Greenhill Biotechnology.

In spite of the fact, Baxter's ultra modern biomedical facilities in Orth an der Donau have to adhere to biosecurity level 3 regulations when handling the live bird flu virus – an artificial, lab engineered virus which Baxter should not have had in the first place – 72 kilos of pandemic material were not only manufactured in Baxter's facilities but also sent irradiated and with a false label to Avir and from there to 16 labs in Austria, Czech Republic, Slovakia and Germany.

If an alert member of staff at the Czech lab BioTest had not broken a seal of one of the packages and tested the "vaccine material" destined to be given to people as seasonal flu, and so discovered the live bird flu virus on February 6th, the world's population could by now have been decimated by a bird flu pandemic and forced vaccinations.

Jon Rappoport

CBS and the Swine Flu

Jon Rappoport's Blog, 22 October 2009
https://blog.nomorefakenews.com/2009/10/

Get this. The CDC stopped testing people for Swine Flu in July. Why? Because CDC assumed there was already an epidemic, and therefore more tests would be waste of time and money.

CBS has been trying to obtain state-by-state numbers for Swine Flu cases compiled, by the CDC, before the testing was stopped. The CDC has refused to come across with those numbers. It's been stonewalling CBS for the last three months.

Why? No answer from the CDC. But the truth is obvious. The actual Swine Flu case numbers don't begin to match the ominous pronouncements about Swine Flu from the CDC, and the case numbers certainly don't match the general press hysteria and fear-mongering.

But CBS didn't stop at the stone wall of the CDC. They went to individual states who continued to test patients for Swine Flu after July, and they obtained some very interesting figures. The figures show that all sorts of illness one might blithely assume was Swine Flu was not. Not Swine Flu.

In California, based on 13,704 tests for suspected Swine Flu, only 2% of the patients had Swine Flu. That's right. 12% had some other kind of flu. And a whopping 86% didn't have flu at all. What did the 86% have? Who knows? A cold? A brief cough? A case of fear generated by the CDC?

Boom. **In Florida**, based on 8,853 tests for suspected Swine Flu, only 17% had Swine Flu. 83% were negative for other flu. So 83% didn't have ANY kind of flu.

In Alaska, based on 722 tests for suspected Swine Flu, only 11% had Swine Flu.

In Georgia, based on 3,117 tests, only 2% had Swine Flu. 2%.

I have to mention that there are at least two problems, even when lab tests for Swine Flu ARE done. First, the so-called Rapid Test, according to the CDC itself, does not definitively identify H1N1. And two–and much more important – none of the usual Swine Flu tests assess the number of Swine Flu viruses in the body of a particular person. Why does that matter? Because you need millions of a particular virus chomping away to even begin to say that virus is contributing to illness.

So we can assume that the very low numbers of actual Swine Flu cases these states are reporting are even lower. Much lower. The degree of lying and obfuscation here is huge. The CDC has been caught with its pants down around its ankles. The "epidemic" is at best a trickle. The game is over.

But of course the hysteria will continue. The CDC will ignore these revelations. The vaccine campaign will continue. The utter bullshit will keep piling higher and higher. The drug companies will keep ringing up the cash register.

President **Obama**, whose cabinet post, Health and Human Services, is in charge of the CDC, will perhaps not even know what is going on. If he does figure it out, he'll do nothing. The train has already left the station. It's too late to suffer the level of executive embarrassment the truth would deliver.

Remember this moment. Remember it, because you know that, in the future, the CDC will be making announcements about other diseases. You'll be able to muster the amount of gargantuan doubt that the CDC deserves. Unless you like being fooled. Unless you like the fear. Unless you like having something, anything to believe in, regardless of the track record.

Hundreds throng US clinic for H1N1 flu vaccine

Reuters, 22 October 2009, 4:34 AM GMT+8
https://www.reuters.com/article/rbssHealthcareNews/idUSN2150410820091021/

Rockville, Maryland, Oct 21 (Reuters) – More than 1,700 people in search of H1N1 swine flu vaccine thronged the public health clinic in a Washington suburb on Wednesday, but in the end many at risk for severe infections were simply turned away.

The long lines support the Center for Disease Control and Prevention's assessment that Americans want the vaccine, despite some highly vocal critics who say they fear it may not be safe.

"They got in line as early as 10 o'clock last night. They were here at midnight. They were here at 5 a.m. The clinic started at 9 a.m.," said Montgomery County health officer Dr. Ulder Tillman. But within 90 minutes, the clinic was out of the injectable vaccine needed by many of those most vulnerable to swine flu: pregnant women and children or adults with underlying health conditions including asthma. "We are not able now to provide vaccine to pregnant women," Tillman told Reuters Television.

There was plenty of vaccine nasal spray from AstraZeneca's MedImmune unit, which is not suitable for some high risk people because of its formulation using a live but weakened form of flu virus.

But health officials had only 249 doses of injectable vaccine because of manufacturing problems that have prompted the U.S. government to cut its production estimates for October from 40 million doses to between 28 million and 30 million.

U.S. Health and Human Services Secretary Kathleen Sebelius told Congress on Wednesday that those problems have been overcome and that production is expected to be back on track early in November. [ID:nN21505080]

County spokeswoman Mary Anderson said local injectable vaccine supplies have been running significantly below expectations, perhaps by as much as 40 percent. "The injectable vaccine we had is what we got last week. We haven't had anything new since then," she said.

The U.S. government has ordered up to 250 million doses of H1N1 vaccine from five companies: AstraZeneca, Sanofi-Aventis SA, Novartis AG, GlaxoSmithKline PLC and CSL Ltd.

Flu vaccine is made using old technology that involves growing the virus in chicken eggs, and it takes months to make a new formulation to match circulating flu strains. Makers of injectable vaccine have had more problems than expected getting vaccine doses from eggs. There have also been problems with new production lines set up to meet the orders.

In suburban Maryland, people said they wanted the protection now because H1N1 is already widespread and expected to intensify as colder weather sets in. They came well-prepared for a long wait. Many dressed in layers against the October chill and brought snacks while some showed up with lawn chairs.

County officials expect to hold H1N1 clinics at public health offices every week and will soon begin vaccinations in local schools.

MailOnline

Swine flu: 'Millions at risk' as postal strike threatens vaccination programme

Daily Mail, 22 October 2009, 08:08 GMT
https://www.dailymail.co.uk/news/article-1221882/Swine-flu-Millions-risk-postal-strike-threatens-vaccination-programme.html

A mass swine flu immunisation programme was launched today as health bosses drew up emergency measures to protect patients ahead of the national postal strike.

Chief Medical Officer Sir Liam Donaldson said he was concerned that those eligible for the H1N1 jab – including those with serious medical conditions and all pregnant women – would not receive letters from their GPs. He said this could put millions of vulnerable people at risk.

It comes as the Communication Workers Union confirmed up to 120,000 members would stage a 48-hour strike from 4am tomorrow morning.
Hopes of a last-minute deal collapsed as the CWU accused Royal Mail and the Government of working together.

Warnings of further action over the Christmas period were also made as the union launched an extraordinary attack on Business Secretary Lord Mandelson, saying he was working 'hand in hand with the Royal Mail' to 'undermine the dispute'.

General secretary Billy Hayes accused him of being the 'minister without responsibility' and said Mr Mandelson 'needs to get his hands dirty'.
Sir Liam called the strike 'extremely unwelcome', adding: 'GPs need to send letters out to patients. We need to get people into GPs' surgeries to give them this life-saving vaccine'.

Hospitals and GP surgeries are looking at ways to minimise the disruption, including phoning people with appointment details and employing couriers to carry test results.
Doctors are also considering using text messages and emails to contact vulnerable patients due to have the swine flu vaccination next week.

Professor Stephen Field, president of the Royal College of General Practitioners, described the planned postal strike as 'extremely unhelpful'. He said: 'In the short term - if it's only for a day or two - we will manage but what will happen is we won't be able to get to people consistently and it will also mess up the system because we will be planning to bring people in in sequence, so we could do without that. – 'But we will get hold of patients because they are local.'

Urging people considered at risk to get the vaccine, Sir Liam said: 'This is the first pandemic for which we have had a vaccine to protect people. – 'I urge everyone in the priority groups to have the vaccine - it will help prevent people in clinical risk groups from getting swine flu and the complications that may arise from it. 'It's important for frontline health and social care workers to have the vaccine.

'It will help prevent them and their families getting the virus from patients, it will stop them passing the virus on to their patients, it will potentially protect them from mutated strains and it will reduce the disruption to NHS services caused by people being absent due to illness.'

GPs will begin receiving deliveries of the vaccine from Monday and will send appointment letters to patients classified as at risk.

Asked how they would get appointment letters to people if a strike goes ahead, Sir Liam said: 'By bundling the mail up and ensuring that it is delivered because some mail will still be delivered for urgent situations, so we are going to try and sort out that little glitch - which isn't a particularly welcome thing to happen in the middle of having this vaccine.'

The immunisation programme offering more than 11 million people the vaccine began with hospitals vaccinating frontline health care workers and their patients who fall into at risk categories against swine flu.

Around two million frontline health and social care workers will be offered the vaccine, as they are classified as at increased risk of infection and of transmitting the infection to susceptible patients.

The vaccination programme will be extended over the coming weeks.

The Department of Health said at-risk groups will be given priority in the following order: people aged over six months and under 65 years in current seasonal flu vaccine clinical at-risk groups; all pregnant women; household contacts of people with compromised immune systems; and people aged 65 and over in the current seasonal flu vaccine clinical at-risk groups.

The Department of Health said this did not include otherwise healthy over-65s, since they appeared to have some natural immunity to the virus.

Patients will be contacted by their GPs if they fall into one of the at-risk categories, the Department said.

The GSK vaccine Pandemrix will be offered to the 'vast majority', with most people needing only one dose of this vaccine for protection.

The campaign comes after Sir Liam announced last week in his weekly briefing that the number of deaths of people in the UK suffering from swine flu has passed 100.

Health Protection Agency estimates released last Thursday showed about 37,000 people have contracted the virus so far in the UK.

Health Secretary Andy Burnham, who was visiting University College Hospital in London to launch the campaign today, said: 'Our best line of defence against swine flu is the vaccine. – 'I'm very pleased to say that the UK is one of the first countries in the world to start vaccinating against this virus.

'The independent committee of experts in the UK has recommended that all those in the at-risk groups should be offered the swine flu vaccine.

'It is also being offered to frontline health and social care workers to protect them and their patients and ensure the NHS is staffed, should it come under pressure this winter.'

THE SCOTSMAN

Lyndsay Moss

First among millions: all Scots may get swine flu jab

The Scotsman, 22 October 2009
https://web.archive.org/web/20091027044629/http://thescotsman.scotsman.com/latestnews/First-among-millions-all-Scots.5755689.jp

The whole population could be offered the swine flu jab in the next six months, experts said yesterday, as the first vaccines were given to patients in Scotland. The H1N1 vaccination campaign began in Glasgow yesterday, with NHS staff and at-risk patients in hospital being given the first jabs.

Scotland's chief medical officer Harry Burns said it was possible that after priority groups were vaccinated, the rest of the population could be offered the vaccine. If this happens, a third wave of the pandemic could potentially be avoided, he said.

The vaccination programme began as a 17th death linked to swine flu in Scotland was announced; a 58-year-old woman from the Borders with significant underlying health conditions.

Health secretary Nicola Sturgeon urged everyone invited by their GP to take up the vaccine offer to help avoid tragedies like the latest death.

It has been estimated that in a worst-case scenario, about 2,000 people in Scotland could die during the swine flu pandemic. This was revised down from earlier assumptions that the figure could hit 5,000.

The Scottish Government said these assumptions did not take into account the effects of vaccination which, depending on uptake, could significantly reduce deaths even further.

Yesterday, Dr Burns and Ms Sturgeon were at the new Victoria Hospital in Glasgow to see patient Adeline Miskelly become the first person in Scotland to receive the vaccine. The 84-year-old, who is being treated on the hospital's rehabilitation ward, was given the jab alongside staff nurse Priscilla Carino. NHS staff are being urged to take up the vaccine.

Only about a fifth of NHS workers have the seasonal flu jab and surveys suggest some may also avoid the new jab. A decision has yet to be taken on whether the vaccine will be offered to others outside the current priority groups, which include people with chronic health problems and pregnant women.

UK governments have ordered enough vaccine to cover the whole population. A decision on further priority groups will be taken at a UK level.

But Dr Burns said it was "not an unrealistic proposition" that the vaccine could be offered to everyone by next May. He said a decision could be made within the next couple of weeks on future target groups. This could include younger people who have been more heavily affected than those in older groups. Some research has suggested young women may be particularly vulnerable.

Supplies of the vaccine have started to arrive in Scotland, with batches set to increase in the coming weeks.

Dr Burns said the NHS expected to have a significant amount of vaccine available for the next phase of the campaign, at the start of December.

"I can't imagine that we wouldn't offer it to healthy people," he said. "But you don't know what might evolve. It might just go away. That's unlikely; but genuinely we are watching an evolving situation."

Ms Sturgeon said it was "possible, perhaps even probable" that the vaccine would be extended to other groups, but a final decision had not yet been made.

Supplies of the vaccine have been distributed across Scotland. Next week, GPs will start inviting at-risk patients in for vaccination, with the hope of covering 1.3 million people by Christmas.

Dr Burns sought to reassure people who may have concerns about the safety of the vaccine.

Concerns have also been raised that the virus could mutate, making the current jab ineffective. But virologist Professor Hugh Pennington said there was no evidence of that happening at the moment.
He said: "There is always the possibility that the virus may suddenly lurch and change. But it has shown absolutely no sign of doing that."

Prof Pennington also said that so-called herd immunity – where larger parts of the population are protected once a significant proportion of people are vaccinated – would not be gained in the first phase of the vaccination campaign. "That is not really the aim. The aim of the exercise is to protect people."

Should my child have the vaccine?
Children in at-risk groups will be offered the vaccine. We encourage parents of these children to have them vaccinated. Swine flu seems to be affecting children and young adults in particular.

I am pregnant and worried about the effect the vaccine might have.
Pregnant women are four times as likely to develop serious complications from swine flu and four of five times more likely to require hospitalisation. Pregnant women would not normally be included in vaccination, but taking the evidence we have into consideration, we believe that pregnant women should be vaccinated.

What if I'm in a high-risk group and haven't heard from my doctor?
You won't have heard from your practice as they have not received supplies of vaccine yet so can't finalise dates for their vaccination clinics yet.

I think I have already had swine flu. Should I have the vaccine?
You should take the vaccine if it is offered. Many people who have been advised they have swine flu will not actually have had it, so it is important that they are vaccinated.

I have taken Tamiflu. Does that have any effect on the vaccine working?
People who have taken Tamiflu should still be vaccinated if they are in one of the at risk-groups or if they are a health or social care worker.

Do I still need to get my usual winter flu jab?
Yes. There is still some seasonal flu around, so take both vaccines if offered.

Is there going to be enough vaccine to cover everyone?
The government has ordered enough vaccine to vaccinate those who require it.

Could the virus mutate and mean that the vaccine is no longer effective?
One of the main worries doctors have is that the virus could mutate at some point. If it does, we will have to alter the vaccine to ensure that it is effective against any new virus that might develop.

Los Angeles Times

Kim Geiger

Sebelius calls for updated vaccine making process

Los Angeles Times, 22 October 2009, 12:00 AM PT
https://www.latimes.com/archives/la-xpm-2009-oct-22-na-swine-flu-health22-story.html

The Health and Human Services secretary says the U.S. is too dependent on foreign countries for production of vaccines, as shown by delays in the release of H1N1 flu shots.

Washington – Health and Human Services Secretary Kathleen Sebelius told Congress on Wednesday that delays in the release of H1N1 flu shots show that the United States is too dependent on other countries for the manufacture of vaccines and that the technology to make them must be improved.

Four of the five manufacturers of H1N1 vaccines are foreign companies – a fact that alarmed lawmakers, who expressed concern about the ability of the federal government to secure enough vaccine to prevent the spread of the virus, known as swine flu.

Some expressed even greater concern that the lag in vaccine production could mean the H1N1 flu shots would arrive too late to do any good, citing a recent study that predicted that swine flu infections would reach their peak this week.

The study by researchers at Purdue University in Indiana projects that 63% of the U.S. population will be infected by the end of this year, with 8% being infected this week.

"H1N1 is very contagious," said Sherry Towers, a Purdue graduate student in statistics and coauthor of the study.

Officials had originally projected that 40 million doses of the vaccine would be available by the end of October, but because of what Sebelius called "glitches" in manufacturing, just 11 million doses have been made available. Officials estimate that 28 million to 30 million doses will be available by the end of the month.

Sebelius said the U.S. is "at the front of the line" in getting the vaccines as they're produced but noted the country needs to expand its manufacturing capacity. – "We are still too dependent in the United States on vaccination production in other countries," Sebelius said at a hearing on the topic.

Vaccine manufacturers worldwide are "using old technology," Sebelius explained, stressing the need to convert from egg-based to cell-based vaccine development.

The good news, she said, is that original projections requiring 40 million doses of the vaccine were developed when scientists had expected that adults would need two shots. Since then, researchers have found that just one dose is required for people older than 10, meaning that the available doses will be spread across more of the population.

"There is enough vaccine, and will be, to vaccinate every American who wants to be vaccinated," Sebelius said. – Fewer than half of Americans get flu shots yearly, even though seasonal flu kills 36,000 people annually, she said.

She added that she expects the number of people getting vaccinated to increase this year because of high public awareness of the H1N1 virus. The flu, including cases involving H1N1, has been blamed in about 2,300 deaths in the U.S. since Aug. 30.

TIMES UNION

Rick Karlin, Scott Waldman

State ends flu shot mandate

Times Union, 23 October 2009
https://www.timesunion.com/local/article/state-ends-flu-shot-mandate-556872.php
Shortage of swine flu vaccine forces end to controversial rule

Gov. David Paterson attributed Thursday's decision to limited supplies of the H1N1 vaccinations, a number of doses far short of the federal government's expected delivery. The decision also tosses out mandated seasonal flu shots.

"Over the last week, the Centers for Disease Control and Prevention acknowledged that New York would only receive approximately 23 percent of its anticipated vaccine supply by the end of the month," Paterson said in a prepared statement. "As a result, we need to be as resourceful as we can with the limited supplies of vaccine currently coming into the state and make sure that those who are at the highest risk for complications from the H1N1 flu receive the first vaccine being distributed right now in New York state."

This summer, the federal government projected 120 million doses would be available by the end of October. This week, the CDC changed expected delivery to just 27.7 million doses. The CDC allowed the state to order only 146,300 doses of vaccine, even though New York's health providers requested more than 1,482,822 doses.

The order from Health Commissioner Richard Daines that health care workers who come in contact with patients, including employees of hospitals, receive the vaccine came earlier this fall and has resulted in at least two lawsuits and protests over what many workers claimed was an unfair intrusion on their freedom of choice.

Daines presented the measure as a simple matter of due diligence for health care workers, whose presence in hospitals and other facilities brought them into close contact with infants, the elderly and other people whose immune systems might be compromised.

Daines said Thursday that it was essential to first get the vaccine to those who need it most.

"We had told hospitals that if they had to choose between vaccinating patients or employees to vaccinate patients first," Daines said in a prepared statement. "This week, the CDC confirmed that most of the national supply of seasonal flu vaccine has been distributed, and that H1N1 vaccine distribution is far behind projections. New evidence is showing that H1N1 can be especially virulent to pregnant women and young people – so they should get vaccinated first."

One of the lawsuits led to a temporary injunction against the order, which mandated that all health care workers get the shot by Nov. 30 or risk losing their jobs.

Opponents of the mandatory shots said they were heartened by the news.

"They should" withdraw the mandate, said Kevin McCashion upon hearing the news. The Colonie businessman helped organize a local protest against the mandate.

Lorna Patterson, a nurse in the emergency room at Albany Medical Center Hospital, was among a group of health care workers who brought a lawsuit to fight the order. She said late Thursday that

she and her fellow nurses were just excited they could concentrate on nursing. She said Paterson recognized the importance of letting people make their own health care decisions.

"I'm just glad our health care organizations can function, knowing they have the stuff they need," she said.

Terence Kindlon, the Albany attorney who brought one of the lawsuits against the state, said the state decided to act in good faith. He said questions remain about whether or not there is even a health crisis. He said it was unfair to single out a small slice of the population upon which to force an untested vaccination.

"I think they tried to sneak this one under the radar," Kindlon said. "The lesson is it's better to play by the rule book."

Kindlon said he believes the decision to back off the mandate will end his court case, but some nurses want to prevent any future mandates, which the governor's office left open as a possibility.

Sue Field, a Poughkeepsie nurse who filed suit against the rule, said she wants to continue her case in order to get a court decision against the mandatory vaccine.

"This is encouraging, but I don't see that at this moment it would stop the lawsuit," she said.

Schweinegrippe: Massenimpfung in Deutschland beginnt

AFP Deutschland, 23 Octobre 2009.
https://www.youtube.com/watch?v=1R4tLJj3OKE

Am Montag beginnt in Deutschland die Massenimpfung gegen die Schweinegrippe. Die Bundesregierung ruft dazu auf, sich gegen das Virus impfen zu lassen. Bislang haben sich schon 25.000 Bundesbürger mit dem neuen H1N1-Erreger infiziert. Die Ansteckungsrate droht zu steigen. Zunächst werden bevorzugt Ärzte, Pfleger und Polizisten geimpft. AFPTV sprach mit einem Arzt, der Gesundheitssenatorin von Berlin und hörte sich in der Bevölkerung zum Impfverhalten um.

WELT

Jens Steffenhagen

Stell Dir vor, es gibt Impfungen und keiner geht hin

WELT, 23 Octobre 2009

https://www.welt.de/fernsehen/article4944364/Stell-Dir-vor-es-gibt-Impfungen-und-keiner-geht-hin.html

Montag beginnen viele Massen-Impfungen gegen die Schweinegrippe. Doch sollte man sich überhaupt impfen lassen? Oder fällt man damit nur auf eine weitere Kampagne der Pharmakonzerne rein? Darüber diskutierte Maybrit Illner mit ihren Gästen. Das Vertrauen in die Redlichkeit der Branche ist gering.

Stell Dir vor es gibt Impfungen – und keiner geht hin... Dieses Szenario könnte jüngsten Umfragen zufolge in der nächsten Woche durchaus eintreten: Mehr als die Hälfte der deutschen Bevölkerung hält es nicht für nötig, sich gegen das H1N1-Virus impfen zu lassen.

Und das trotz einer gewaltigen PR-Offensive seitens der Politik und der Arzneimittelindustrie. Denn spätestens seit die Weltgesundheitsorganisation (WHO) die höchste Pandemie-Warnstufe ausgerufen hat, stellen die Behörden in vielen Ländern Hunderte von Millionen Euro für Medikamente bereit.

Dazu überbieten sich die Boulevardzeitungen beinahe täglich mit neuen Horror-Zahlen: Bis zu 35.000 Menschen könnten in diesem Winter allein in Deutschland an der Schweinegrippe sterben, verkünden Experten – und sorgen mit solch düsteren Prophezeiungen für gesteigerte Auflagen und gigantische Umsätze der Pharmafirmen.

"Impfen. Spritzen. Schröpfen. Geht's ums Geschäft oder unsere Gesundheit?" fragte Maybrit Illner folgerichtig ihre Gäste. So ausladend wie der Titel es suggerierte wurden die Praktiken im Gesundheitswesen allerdings nicht unter die Lupe genommen – man blieb im Wesentlichen bei der Diskussion um die größte Massenimpfung in der Geschichte der Bundesrepublik.

Die stößt in den letzten Tagen auf immer offenere Kritik. Am Wochenende war bekannt geworden, dass die Bundesregierung, Bundesbeamte und Soldaten der Bundeswehr einen anderen Impfstoff bekommen sollen als Otto Normalverbraucher – der Tropfen, der die Kanüle zum Überlaufen brachte.

Das Misstrauen der Bürger ist dabei durchaus berechtigt, denn die Medikamente, die ab Montag eingesetzt werden, sind neu entwickelt worden. Eine Pharmakovigilanz, eine laufende und systematische Überwachung der Arzneimittel konnte nicht stattfinden. "Ein Medikament wird vor der Zulassung lediglich von einigen hundert Personen getestet. Ob die Impfstoffe sicher sind, wissen wir derzeit nicht.

Das Gegenteil zu behaupten, wie es einige Politiker jetzt tun, ist unseriös", meinte Wolf-Dieter Ludwig, Vorsitzender der Arzneimittelkommission der deutschen Ärzteschaft. Die ersten Patienten dürfen sich durchaus als Versuchskaninchen fühlen, wenn auch das Risiko schwerer unerwünschter Nebenwirkungen sehr gering ist.

Ludwig, der in Illners Runde die Fahne der Skeptiker hochhielt, wies zurecht darauf hin, dass der Krankheitsverlauf der Schweinegrippe ungefährlicher ist, als der einer normalen Influenza: Lediglich zwei der 23.000 erkrankten Deutschen starben schließlich an dem Virus.

Ist die Aktion also eher "eine neue Abwrackprämie für die Pharmafirmen ", wie ein Zuschauer mutmaßte? Nein, meinte Barbara Sickmüller vom Bundesverband der Pharmazeutischen Industrie: "Noch kann niemand vorhersagen, wie sich die Krankheit im Januar oder Februar ausbreiten wird. Wir sollten lieber den Beschäftigten danken, die Tag und Nacht gearbeitet haben, um so schnell wie möglich ein Medikament zu entwickeln." Der Bayerische Gesundheitsminister Markus Söder stieß ins gleiche Horn: "Wir dürfen nicht vergessen, welche Verdienste die Pharmaindustrie erworben hat."

Dass der medizinische Fortschritt unser Leben entscheidend verbessert, ist unbestritten. Diesen Industriezweig als karitative Vereinigung darzustellen, verklärt die Realität allerdings ganz gewaltig. Schließlich handeln die Firmen nach den gleichen Marktgesetzen von Angebot und Nachfrage wie jeder andere Wirtschaftszweig. Inwieweit sie diese sogar selber forcieren, verdeutlichte ein Einspieler, der das Budget der Pharmakonzerne anschaulich aufsplittete: Vierzig Prozent der aufgewandten Kosten gehen ins Marketing, lediglich zehn Prozent in die Forschung.

Kritik an der Geschäftspolitik der Arzneimittelhersteller gibt es seit vielen Jahren. Ebenso den Vorwurf, sie bringe aus ökonomischen Erwägungen Medikamente mit schweren Nebenwirkungen auf den Markt. Spektakuläre Fälle wie Contergan oder Lipobay sind noch jedem in Erinnerung. Den betroffenen Konzernen wohl auch: Die Bayer-Aktien sanken um fünf Milliarden Euro, nachdem man verkünden musste, dass der Blutdrucksenker Lipobay vom Markt genommen wird.

Laut Wolf-Dieter Ludwig liegt hier ein "Systemfehler" vor: Neue Medikamente würden oftmals extrem teuer angeboten, bevor ihre Verträglichkeit und Wirksamkeit in langen klinischen Studien bewiesen wurde. Die Firmen verdienen also besonders in den ersten Jahren an den Mitteln, bevor Konkurrenzprodukte die Preise verderben – ein riskanter Anreiz.

Auch jetzt macht die Branche ein ausgezeichnetes Geschäft mit der Unsicherheit: Insgesamt kosten die bestellten 50 Millionen Dosen Impfstoff rund eine Milliarde Euro. Der Umsatz mit Grippemitteln hat sich etwa beim Pharmariesen Roche in den letzten fünf Jahren verzehnfacht, wie eine Grafik der Illner-Redaktion verdeutlichte.

Die Frage, ob man sich nun gegen die Schweinegrippe impfen lassen soll oder nicht, konnte die Runde erwartungsgemäß nicht abschließend klären. Eine Entscheidung zwischen Pest und Cholera, wie es scheint – auch wenn wohl weder die Hysterie um eine bevorstehende Pandemie noch die übertriebene Angst vor einem neuen Contergan-Skandal berechtigt sind.

Erstklassig geschützt

Zeit, 23 Oktober 2009, 08:51 Uhr
https://web.archive.org/web/20091225125833/http://www.zeit.de/2009/44/01-Impfung-Schweinegrippe

Aller Aufregung zum Trotz: Die Impfung gegen die Schweinegrippe hilft – und die angeblich schlechtere ist die bessere.

Lange Zeit sah es so aus, als sei Deutschland auf eine mögliche Schweinegrippeepidemie bestens vorbereitet. Scheinbar weitsichtig, orderten die Bundesländer große Mengen Impfstoff, Experten klärten die Bevölkerung über die Grippegefahr auf, allen Unkenrufen zum Trotz wurde der Impfstoff rechtzeitig fertig. Seitdem aber bekannt wurde, dass für Bundeswehrsoldaten, Spitzenpolitiker und hohe Beamte 200.000 Dosen eines Sonderimpfstoffs bestellt wurden, ist alle Besonnenheit dahin.
=> Hartmut Wewetzer. Verstärkte Verunsicherung. – Zeit, 19 Oktober 2009, 10:28 Uhr
https://web.archive.org/web/20091230234109/http://www.zeit.de/wissen/2009-10/impfung-schweinegrippe-regierung

Die Bürger sind zu Recht verunsichert, es scheint, als ob für die herrschende Klasse nur das Beste, für die Massen das Zweitbeste gut genug sei. Dass unter solchen Umständen viele an der Impfung zweifeln, ist nur zu verständlich.

Damit ist all das in Gefahr, worauf Institutionen wie das Berliner Robert Koch-Institut oder das für Impfungen zuständige Paul-Ehrlich-Institut hingearbeitet haben: eine Impfkampagne, mit der sich zum ersten Mal ein Grippesturm im Ansatz stoppen ließe. Zwar ist es zurzeit noch relativ ruhig an der deutschen Grippefront. Aber in Ländern wie Argentinien und Australien konnte man bereits beobachten, wie heftig das neuartige Grippevirus H1N1/09 zuschlagen kann, wenn die Temperaturen sinken. Eine präventive Impfung wäre da der beste Weg, um eine Erkrankungswelle zu verhindern.
=> https://web.archive.org/web/20091227063441/http://www.zeit.de/2009/34/M-Grippe-Argentinien

Nun jedoch wird in Deutschland weniger über eine drohende Grippeepidemie, als vielmehr über eine Zweiklassenmedizin debattiert. Doch so nachvollziehbar der Vorwurf ist, so falsch ist er. Zunächst ist keineswegs klar, ob der für Politiker georderte Impfstoff, der keine sogenannten Wirkstoffverstärker enthält, wirklich der bessere ist. Es stimmt zwar, dass ein reiner Impfstoff ohne Verstärker auch weniger Nebenwirkungen hat; er ruft seltener Schmerzen an der Impfstelle, Schwellungen oder Fieber hervor. Doch die bessere Verträglichkeit wird mit einem schwerwiegenden Nachteil erkauft: Der angebliche »Premiumimpfstoff« führt zu einem schwächeren Impfschutz.

Der Massenimpfstoff mit den Wirkverstärkern dagegen, das legen Tierversuche nahe, schützt nicht nur vor H1N1/09, sondern voraussichtlich auch vor dessen Varianten. Sollte das zirkulierende Grippevirus tatsächlich eines Tages mutieren – was viele Experten befürchten –, wären gerade Soldaten, Politiker und Beamte, in deren Adern das Ausnahmevakzin zirkuliert, schutzlos.

Dazu kommt ein weiterer Aspekt: Ohne die viel geschmähten Zusatzstoffe wäre eine flächendeckende Impfung in Deutschland im Übrigen schlicht nicht realisierbar gewesen. Die Wirkverstärker dienen nämlich dazu, wie ihr Name sagt, die Wirkung des Impfstoffs zu verstärken. Erst durch ihren Einsatz

ließen sich innerhalb von fünf Monaten weltweit 440 Millionen Impfdosen herstellen – ohne Zusatz wären es nur 110 Millionen gewesen.

All das geht in der jetzigen Aufregung über die angebliche Zweiklassenmedizin unter. Kaum Gehör findet auch das Argument, dass es in solchen Fragen immer auch um die feine Balance zwischen individuellen Interessen und dem Wohl aller geht. Diese Grippe trifft, anders als die übliche Wintergrippe, vor allem die Jüngeren, die dann ein bis zwei Wochen im Beruf ausfallen. In Mexiko sank wenige Wochen nach Ausbruch von H1N1/09 das Bruttoinlandsprodukt um 0,5 Prozent. Je früher viele Menschen geimpft werden, desto besser. Davon profitieren letztlich auch jene, die sich der Impfung verweigern.

H1N1 vaccinations rolled out in UK

CNN, 24 October 2009, 14:32 GMT (22:32 HKT)
https://edition.cnn.com/2009/HEALTH/10/24/h1n1.flu.vaccinations/index.html

London, England (CNN) – A mass H1N1 immunization program began in the UK Wednesday, with the country's health minister urging all priority groups to take up the vaccine.

Health and social care workers are among those identified in the "priority" group given first access to the vaccine against the H1N1 virus, commonly known as swine flu.

Others include pregnant women, those over 65, people with asthma, diabetes and those having cancer treatment, the country's Department of Health has said.

From Monday, this group will be given appointments to visit doctors surgeries to receive the vaccine.

The vast majority of people will be offered GlaxoSmithKline's Pandemrix vaccination, which is effective after one dose but made using chicken eggs, according to the Department of Health.

Those allergic to eggs will instead be offered Baxter's Celvapan, which requires two doses three weeks apart.

The Department of Health says that it has placed enough orders for the entire UK population of 60 million to be vaccinated against H1N1 swine flu.

Health Secretary Andy Burnham said in a statement: "Our best line of defence against swine flu is the vaccine. I'm very pleased to say that the UK is one of the first countries in the world to start vaccinating against this virus."

The country's National Health Service (NHS) staff , who have in the past been reluctant to take the seasonal flu vaccines, were urged to take the swine flu jab.

Chief Medical Officer Sir Liam Donaldson said in a statement: "It's important for frontline health and social care workers to have the vaccine.

"It will help prevent them and their families getting the virus from patients, it will stop them passing the virus onto their patients, it will potentially protect them from mutated strains and it will reduce the disruption to NHS services caused by people being absent due to illness."

Nearly 400,000 people worldwide have contracted laboratory-confirmed cases of swine flu and more than 4,700 people have died from the illness since it was first identified in Mexico and the U.S. in April, World Health Organization said last week.

A total of 228 deaths have been reported in Europe since April, according to the European Centre for Disease Prevention and Control.

France started immunizing health-care workers against swine flu Tuesday. Germany will roll out its vaccine program next week and Ireland in early November, while Spain is expected to start vaccinating in mid-November.

the WHITE HOUSE
PRESIDENT BARACK OBAMA

Barack Obama
President of the United States of America

Declaration of a National Emergency with Respect to the 2009 H1N1 Influenza Pandemic

The White House, Office of the Press Secretary, 24 October 2009
https://obamawhitehouse.archives.gov/the-press-office/declaration-a-national-emergency-with-respect-2009-h1n1-influenza-pandemic-0

On April 26, 2009, the Secretary of Health and Human Services (the "Secretary") first declared a public health emergency under section 319 of the Public Health Service Act,42 U.S.C. 247d, in response to the 2009 H1N1 influenza virus. The Secretary has renewed that declaration twice, on July 24,2009, and October 1, 2009. In addition, by rapidly identifying the virus, implementing public health measures, providing guidance for health professionals and the general public, and developing an effective vaccine, we have taken proactive steps to reduce the impact of the pandemic and protect the health of our citizens. As a Nation, we have prepared at all levels of government, and as individuals and communities, taking unprecedented steps to counter the emerging pandemic. Nevertheless, the 2009 H1N1 pandemic continues to evolve. The rates of illness continue to rise rapidly within many communities across the Nation, and the potential exists for the pandemic to overburden health care resources in some localities.Thus, in recognition of the continuing progression of the pandemic, and in further preparation as a Nation, we are taking additional steps to facilitate our response.

NOW, THEREFORE, I, BARACK OBAMA, President of the United States of America, by virtue of the authority vested in me by the Constitution and the laws of the United States,including sections 201 and 301 of the National Emergencies Act (50 U.S.C. 1601 et seq.) and consistent with section 1135 of the Social Security Act (SSA), as amended (42 U.S.C. 1320b-5), do hereby find and proclaim that, given that the rapid increase in illness across the Nation may overburden health care resources and that the temporary waiver of certain standard Federal requirements may be warranted in order to enable U.S. health care facilities to implement emergency operations plans, the 2009 H1N1 influenza pandemic in the United States constitutes a national emergency. Accordingly, I hereby declare that the Secretary may exercise the authority under section 1135 of the SSA to temporarily waive or modify certain requirements of the Medicare, Medicaid, and State Children's Health Insurance programs and of the Health Insurance Portability and Accountability Act Privacy Rule throughout the duration of the public health emergency declared in response to the 2009 H1N1 influenza pandemic. In exercising this authority, the Secretary shall provide certification and advance written notice to the Congress as required by section 1135(d) of the SSA (42 U.S.C. 1320b-5(d)).

IN WITNESS WHEREOF, I have hereunto set my hand this twenty-third day of October, in the year of our Lord two thousand nine, and of the Independence of the United States of America the two hundred and thirty-fourth.

BARACK OBAMA

Chapter 7

Side effects:

Illnesses and Deaths presumably

Related to or Caused by

Swine Flu Vaccine

https://www.art-east.ru/2038466/

Could severe underlying medical conditions cause the death of a patient who got a vaccine?

Should a doctor recommend vaccination to a patient who presumably may die soon? Should a doctor recommend vaccination to a patient who may die in a week, or in a month, or during five-six months?

One may assume that if the patient's condition suggests his death within 5-6 months, his condition is an **absolute contraindication** for vaccination.

Thus, **any death** (excluding accidental death) that occurs within 5-6 months after vaccination is a consequence of the vaccination.

The unrecognized health condition of the patient, which, after vaccination, led to a death, depending on the case, is a sign of violation of the professional code of the doctor and, depending on the case, should entail administrative or criminal punishment.

SWINE FLU

Swine Flu Epidemic/ H1N1 Vaccine Deaths and Injuries

Swine Flu, 6 March 2009
http://vaccineriskawareness.com/swine-flu/

Now in April we are hearing of dozens of cases of people in Mexico, dying of 'swine flu'. I think the Baxter accident and the swine flu are related.

It's emerged that virulent H5N1 bird flu was sent out by accident from an Austrian lab last year and given to ferrets in the Czech Republic before anyone realised. As well as the risk of it escaping into the wild, the H5N1 got mixed with a human strain, which might have spawned a hybrid that could unleash a pandemic.

Last December, the Austrian branch of US vaccine company Baxter sent a batch of ordinary human H3N2 flu, altered so it couldn't replicate, to Avir Green Hills Biotechnology, also in Austria. In February, a lab in the Czech Republic working for Avir alerted Baxter that, unexpectedly, ferrets inoculated with the sample had died. It turned out the sample contained live H5N1, which Baxter uses to make vaccine. The two seem to have been mixed in error.

Markus Reinhard of Baxter says no one was infected because the H3N2 was handled at a high level of containment. But Ab Osterhaus of Erasmus University in the Netherlands says: "We need to go to great lengths to make sure this kind of thing doesn't happen."

Accidental release of a mixture of live H5N1 and H3N2 viruses could have resulted in dire consequences. While H5N1 doesn't easily infect people, H3N2 viruses do. If someone exposed to a mixture of the two had been simultaneously infected with both strains, he or she could have served as an incubator for a hybrid virus able to transmit easily to and among people.

PDS Pharmacoepidemiology & Drug Safety — ispe Official Journal of the International Society for Pharmacoepidemiology

Rue-Cover A, Iskander J, Lyn S, Burwen DR, Gargiullo P, Shadomy S, Blostein J, Bridges CB, Haber P, Satzger RD, Ball R, Seward JF.

Death and serious illness following influenza vaccination: a multidisciplinary investigation

Pharmacoepidemiol Drug Saf. 2009 Jun; 18 (6): 504-511
doi: 10.1002/pds.1743. PMID: 19373848 // https://pubmed.ncbi.nlm.nih.gov/19373848/

Abstract

Purpose: To evaluate a possible association between influenza vaccination and four deaths and four serious illnesses among 114 recent influenza vaccinees in a long-term care facility (LTCF) and two deaths from a nearby physician's office. All had received vaccine from the same lot (Lot A).

Methods: Field investigation including (1) a retrospective cohort study among LTCF residents who received Lot A or other influenza vaccine, (2) review of medical records of cases of death or serious illness, (3) active surveillance of deaths among 1500 community based Lot A vaccinees and (4) laboratory testing of vaccine from available Lot A vials.

Results: Medical record reviews showed no common clinical syndrome or cause of death. Laboratory testing of Lot A samples revealed no evidence of tampering and no differences compared to an unrelated lot. The risk of death or hospitalization was not significantly different between persons who received Lot A versus a comparison lot, Lot B (incidence rate ratio (IRR) = 0.9, 95%CI = 0.3-3.3).

Conclusions: There was no clinical or biological evidence pointing to inherent vaccine safety issues, nor was there a detectable increased risk of death or hospitalization among persons vaccinated with Lot A. Lot specific clustering of adverse events (AEs) may reflect medical events causally unrelated to vaccination. Rapid investigations of potential AEs are important to ensure vaccine safety and to maintain public and healthcare provider confidence in vaccines.

The Idaho Observer

Russell Blaylock

Vaccine May be more Dangerous than Swine Flu

The Idaho Observer, 1 July 2009
https://web.archive.org/web/20110106111319/http://proliberty.com/observer/20090723.htm
https://web.archive.org/web/20090711181633/https://www.newsmax.com/health/vaccine_swine_flu/2009/07/07/232717.html/

One can continue to believe that the global gurus of public health are responding appropriately to the swine flu emergency and willingly take the shot if they choose to do so. But such trust and complacency requires the omission of one key factiod: The vaccine contains an oil-based "adjuvant" containing "squalene." Adjuvants are used to boost an immune response. Squalene, which is a causal factor in Gulf War illness, causes crippling arthritis and premature death in about 100 percent of lab animals and has been associated with autoimmune diseases and premature death in people as well. Early reports of trials with the H1N1 vaccine show that the vaccine is already maiming and killing people. It appears certain that those who take the vaccine may not get the flu but can expect to die a painful and premature death – and WHO et. al know it.

An outbreak of swine flu occurred in Mexico this spring that eventually affected 4,910 Mexican citizens and resulted in 85 deaths. By the time it spread to the United States, the virus caused only mild cases of flu-like illness.

Thanks to air travel and the failure of public health officials to control travel from Mexico, the virus spread worldwide. Despite predictions of massive numbers of deaths and the arrival of doomsday, the virus has remained a relatively mild disease, something we know happens each year with flu epidemics.

Cases to date as of July 7, 2009

Worldwide, there have only been 311 deaths out of 70,893 cases of swine flu. In the United States, 27,717 cases have resulted in 127 deaths. Every death is a tragedy, but such a low death rate should not be the basis of a draconian government policy.

It is helpful to recall that the Centers for Disease Control, with the collusion of the media, constantly tell us that 36,000 people die from the flu each year, a figure that has been shown to be a lie. In this case, we are talking about 300 plus deaths for the entire world.

From whence this novel strain?

This virus continues to be an enigma for virologists. In the April 30, 2009 issue of Nature, a virologist was quoted as saying. Where the hell it got all these genes from we don't know. Extensive analysis of the virus found that it contained the original 1918 H1N1 flu virus, the avian flu virus (bird flu), and two new H3N2 virus genes from Eurasia. Debate continues over the possibility that swine flu is a genetically engineered virus.

Scandal.

Naturally, vaccine manufacturers have been in a competitive battle to produce the first vaccine. The main contenders have been Baxter Pharmaceuticals and Novartis Pharmaceuticals, the latter of which recently acquired the scandal-ridden Chiron vaccine company. Both of these companies have had agreements with the World Health Organization to produce a pandemic vaccine.

Contamination.

The Baxter vaccine, called Celvapan, has had fast track approval. It uses a new vero cell technology, which utilizes cultured cells from the African green monkey. This same animal tissue transmits a number of vaccine-contaminating viruses, including the HIV virus.

More contamination.

The Baxter company has been associated with two deadly scandals. The first event occurred in 2006 when hemophiliac components were contaminated with HIV virus and injected in tens of thousands of people, including thousands of children. Baxter continued to release the HIV contaminated vaccine even after the contamination was known.

Accidental release.

The second event occurred recently when it was discovered that Baxter had released a seasonal flu vaccine containing the bird flu virus, which would have produced a real world pandemic, to 18 countries. Fortunately, astute lab workers in the Czech Republic discovered the deadly combination and blew the whistle before a worldwide disaster was unleashed.

Despite these two deadly events, WHO maintains an agreement with Baxter Pharmaceuticals to produce the world's pandemic vaccine.

[Note: WHO announced that it would launch an investigation into Baxter's "accidental" release of H5N1-contaminated flu vaccine that killed lab animals (ferrets) in the Czech Republic. No investigation has ever been conducted. ~ DWH].

Squalene.

Novartis, the second contender, also has an agreement with WHO for a pandemic vaccine. Novartis appears to have won the contract, since their vaccine is near completion. What is terrifying is that these pandemic vaccines contain ingredients, called immune adjuvants, that a number of studies have shown cause devastating autoimmune disorders, including rheumatoid arthritis, multiple sclerosis and lupus.

Animal studies using this adjuvant have found them to be deadly. A study using 14 guinea pigs found that when they were injected with the special adjuvant, only one animal survived. A repeat of the study found the same deadly outcome.

So, what is this deadly ingredient? It is called squalene, a type of oil. The Chiron company, maker of the deadly anthrax vaccine, makes an adjuvant called MF-59 which contains two main ingredients of concern qualene and gp120. A number of studies have shown that squalene can trigger all of the above-mentioned autoimmune diseases when injected.

The MF-59 adjuvant has been used in several vaccines. These vaccines, including tetanus and diphtheria, are the same vaccines frequently associated with adverse reactions.

[Note: All higher organisms produce squalene. The squalene used as a vaccine adjuvant is a fish oil, particularly shark liver oil. The problem with injected squalene is that it signals the body to attack its own essential fatty acids. Combined with other vaccine ingredients, the result is autoimmunity, where the body begins attacking its own tissues. ~ DWH]

Questionable studies.

I reviewed a number of studies on this adjuvant and found something quite interesting. Several studies done on human test subjects found MF-59 to be a very safe immune adjuvant. But when I checked to see who did these studies, I found to no surprise that they were done by the Novartis Pharmaceutical Company and Chiron Pharmaceutical Company, which have merged. They were all published in prestigious medical journals. Also, to no surprise, a great number of studies done by independent laboratories and research institutions all found a strong link between MF-59 and autoimmune diseases.

Gulf War Illness.

Squalene in vaccines has been strongly linked to the Gulf War Syndrome. In August 1991, Anthony Principi, Secretary of Veterans Affairs admitted that soldiers vaccinated with the anthrax vaccine from 1990 to 1991 had an increased risk of 200 percent in developing the deadly disease amyotrophic lateral sclerosis (ALS), also called Lou Gehrig's disease. The soldiers also suffered from a number of debilitating and life-shortening diseases, such as polyarteritis nodosa, multiple sclerosis (MS), lupus, transverse myelitis (a neurological disorder caused by inflammation of the spinal cord), endocarditis (inflammation of the heart's inner lining), optic neuritis with blindness and glomerulonephritis (a type of kidney disease).

Brain inflammation.

Because squalene, the main ingredient in MF-59, can induce hyperimmune responses and induce autoimmunity, a real danger exists for prolonged activation of the brain's immune cells, the microglia. This type of prolonged activation has been strongly associated with such diseases as multiple sclerosis, Alzheimer's disease, Parkinson's disease, ALS and possibly vaccine-related encephalitis. It has been shown that activation of the systemic immune system, as occurs with vaccination, rapidly activates the brain's microglia at the same time, and this brain inflammation can persist for long periods.

So, how would the gp120 get into the brain? Studies of other immune adjuvants using careful tracer techniques have shown that they routinely enter the brain following vaccination. What most people do not know, even the doctors who recommend the vaccines, is that most such studies by pharmaceutical companies observe the patients for only one to two weeks following vaccination – these types of reactions may take months or even years to manifest.

The profit motive.

It is obvious that the vaccine manufacturers stand to make billions of dollars in profits from this WHO/government-promoted pandemic. Novartis, the maker of the new pandemic vaccine, recently announced that they would not give free vaccines to impoverished nations' everybody pays.

Grim reality.

One must keep in mind that once the vaccine is injected, there is little you can do to protect your-selves at least by conventional medicine. It will mean a lifetime of crippling illness and early death.

The best medicine.

There are much safer ways to protect oneself from this flu virus, such as higher doses of vitamin D3, selective immune enhancement using supplements, and a good diet.

Dr. Russell Blaylock, is a board certified neurosurgeon, author and lecturer. An expert on nutrition, aspartame, MSG and vaccines, he is also editor of the widely distributed Blaylock Wellness Report.

Note: The subheads and boldface preceeding certain paragraphs were added to the original text to highlight the ground Dr. Blaylock is covering in this brief article. Each point he makes could be books in themselves but his intent was to show that the much publicized "novel" flu strain was likely created in a lab by entities connected to the scandal-ridden pharmaceutical companies being rewarded with huge contracts to produce millions (billions) of vaccines that contain a specific ingredient known to cause chronic illnesses and early death.

The most comprehensive journalistic investigation on the politics and effects of squalene is "Vaccine A: The Covert Government Experiment That's Killing Our Soldiers and Why GIs Are Only the First Victims" by Gary Matsumoto (2004). The book can be ordered online or through your local bookseller.

David Icke

Flu is not the Biggest Danger ... It's The Vaccine!

David Icke.com, 26 July 2009
https://www.bibliotecapleyades.net/ciencia/ciencia_influenza32.htm
https://web.archive.org/web/20090730000644/http://www.daily.pk/7471/flu-is-not-the-biggest-danger-its-the-vaccine/

These are challenging times and we need to stay calm and think things through - not just panic and react. Fear, panic and emotional reaction got us into this mess and it is certainly not going to get us out of it. We also need to realize - here, now - that we have long crossed the line into a fully-fledged fascist dictatorship. It has hidden itself to most people this far, but it is about to lift the veil.

It is no longer an option to do nothing or passively acquiesce to authority out of fear or apathy. Or, at least, it's not if we care about our freedoms and, most importantly, those of our children and grandchildren who will have to live almost their entire lives under a global jackboot of sheer, undiluted evil.

The word 'evil' is much overused and I don't say it lightly; but we are dealing with evil in the sense that the word is the reverse of 'live'. Those behind the conspiracy to cull the human population and turn the rest into little more than computer terminals are anti-life. They have no respect for it and no empathy with those who suffer the consequences of their actions, no matter how appalling.

I have been warning of what was coming for nearly 20 years and it is not 'coming' any more - it's here. No more excuses from anyone, please. We have to deal with it. We have to draw a line in the sand and say no more.

Never was this more important than with the conspiracy to force swine flu vaccination upon the global population. The swine flu virus was created in a laboratory to generate mass panic with the specific intention of forcing everyone to have the vaccine. Problem-Reaction-Solution.

This 'natural' swine flu virus apparently contains genes from humans, birds and pigs from several continents. If you concoct and release a virus and then implement a clearly long-planned mass vaccination program, there can be only one sensible conclusion: swine flu is not the biggest danger here - it's the vaccine.

The scale and speed of the planned vaccination program is insane given that the overwhelming majority of those who have contracted the virus have had very mild symptoms.

Dr Peter Holden of the Rothschild-controlled British Medical Association said that although swine flu was not causing serious illness they were eager to start a mass vaccination campaign, beginning with 'priority groups'. Ugh?? This is not about public health and never was.

Those administering the vaccinations have no clue what is in them or their potential effect. They are just repeaters thinking what they are told to think and doing what they are told to do. Only those at the core of the conspiracy, and those who bother to research it, know what the game is.

The Austrian journalist, Jane Bürgermeister, has filed criminal charges with the FBI against, World Health Organization (WHO), United Nations, Barack Obama, a Rockefeller, a Rothschild and others, ...over a plot she uncovered to cull the population with a deadly swine flu vaccine.

She said that bird flu and swine flu have been developed in laboratories and released on the public with the aim of mass murder through vaccination. Her filed document is called Bioterrorism Evidence. She writes here about the United States, but what she says applies everywhere:

'There is evidence that an international corporate criminal syndicate, which has annexed high government office at Federal and State level, is intent on carrying out a mass genocide against the people of the United States by using an artificial (genetic) flu pandemic virus and forced vaccine program to cause mass death and injury and depopulate America in order to transfer control of the United States to the United Nations and affiliated security forces (UN troops from countries such as China, Canada, the UK and Mexico).

There is proof many organizations – World Health Organization, UN as well as vaccine companies such as Baxter and Novartis – are part of a single system under the control of a core criminal group, who give the strategic leadership, and who have also funded the development, manufacturing and release of artificial viruses in order to justify mass vaccinations with a bioweapon substance in order to eliminate the people of the USA, and so gain control of the assets, resources etc... of North America.

МИКРОБЫ И ПАРАЗИТЫ

Дэвид Айк

Не так страшен грипп, как его вакцина!
Перевод статьи Дэвида Айка о вакцине A/H1N1

Микробы и Паразиты
https://mikroby-parazity.ru/index.php?option=com_content&view=article&id=28&Itemid=34
http://www.kunpendelek.ru/library/westmed/articles-vakcination/not-bad-flu/
http://misto.zp.ua/article/partners3492.html

Мы живем в отчаянные времена, но не следует поддаваться панике. Прежде чем реагировать на происходящее, надо его спокойно и тщательно осмыслить. Страх, паника и чисто эмоциональные реакции ввергли нас в нынешний хаос и никоим образом не помогут нам выбраться из него. Мы также должны осознать, здесь и сейчас, что фашистская диктатура давным давно не угроза, а объективная действительность. До сих пор многие ее не замечали, но теперь не видеть ее попросту невозможно.

Бездействие и смиренная покорность властям из страха или апатии - больше не выход. По крайней мере это не выход, если наша свобода еще что-то значит для нас, а особенно свобода наших детей и внуков, которых мы обрекаем на жизнь под глобальным каблуком абсолютного, неприкрытого зла.

Слово "зло” мы сегодня слышим так часто, что почти забыли его значение. Зло - это антижизнь. В английском языке разница между словами "зло” (”evil”) и "жить” (”live”) только в порядке букв: зло - это вывернутая наизнанку жизнь. Конспираторы, вознамерившиеся сократить численность населения планеты в несколько раз и превратить оставшихся в нечто вроде компьютерных терминалов, выворачивают наизнанку само понятие жизни.

Они не испытывают ни малейшего уважения к ней и ни малейшего сострадания к жертвам их леденящих кровь преступлений.О том, что такое время настанет, я предупреждал в течение почти 20 лет. Сегодня предупреждать поздно: это время уже наступило. Поздно и искать оправдания. Теперь надо что-то с этим делать. Провести черту на песке и сказать: стоп!

Никогда прежде ситуация не была столь серьезной, как в связи с нынешним намерением провести принудительную вакцинацию всего населения планеты. Вирус свиного гриппа был создан в лаборатории с целью спровоцировать массовую панику и представить вакцину как единственное спасение. Проблема - Реакция - Решение. Якобы "натуральная” вакцина, о которой идет речь, содержит человеческие, свиные и птичьи гены с нескольких континентов.

Если вирус создается и выпускается на волю, а для борьбы с ним осуществляется программа вакцинации, спланированная многие годы назад, то разумный вывод напрашивается только один: по-настоящему опасен не свиной грипп, опасна вакцина!

Масштабы и быстрота осуществления запланированной программы вакцинации выглядят абсурдными в сравнении с легкими недомоганиями, отмеченными у пораженных вирусом. Д-р Питер Холден из контролируемой кланом Ротшильдов Британской медицинской ассоциации заявил, что, хотя свиной грипп не является серьезным заболеванием, массовую вакцинацию все же следует провести, начиная с "приоритетных групп”. Как вам это нравится?! О здоровье населения здесь речи нет и никогда не было.

Ответственные за проведение вакцинации не имеют никакого представления ни о составе вакцины, ни о ее возможных побочных эффектах. Они обычные исполнители, думающие то, что им сказано думать, и делающие то, что им сказано делать. Только ограниченному кругу людей, составляющих ядро конспирации, и немногочисленным исследователям-энтузиастам известны ставки в этой игре.

Австрийский журналист Джейн Бюргермейстер передала в Федеральное бюро расследований США досье с обвинением Всемирной организации здравоохранения (ВОЗ), Организации Объединенных Наций, Барака Обамы, кланы Рокфеллеров и Ротшильдов, а также несколько других учреждений и лиц, в организации заговора с целью уничтожения значительной части населения планеты путем введения людям смертельной вакцины якобы против свиного гриппа.

Она утверждает, что оба гриппа, куриный и свиной, были разработаны в лабораториях с целью массового уничтожения людей путем вакцинации. Папка с собранными ею документами озаглавлена: "Доказательства обвинения в биотерроризме". В нижеприведенном отрывке говорится о Соединенных Штатах, но написанное Джейн Бюргермейстер относится ко всем странам без исключения:

"Существуют документальные подтверждения того, что международный корпоративный преступный синдикат, проникший в высшие правительственные круги страны и отдельных штатов, намеревается осуществить акт геноцида против народа Соединенных Штатов путем использования искусственно (генетически) созданного вируса гриппа и программы принудительной вакцинации с целью массового уничтожения жителей, нанесения вреда их здоровью и депопуляции Америки с последующим переходом власти в Соединенных Штатах к Организации Объединенных Наций и силам безопасности под ее командованием (подразделения войск ООН из Китая, Канады, Великобритании и Мексики).

Документы свидетельствуют, что многие организации - Всемирная организация здравоохранения, ООН, а также компании - производители вакцин, такие как Baxter и Novartis - являются частями единой структуры под контролем преступной группы, определяющей стратегию и финансировавшей разработку, производство и распространение искусственных вирусов для обоснования массовой вакцинации с применением вещества, являющегося биологическим оружием, с целью уничтожения населения США и последующего завладения ценностями, ресурсами и т. п. Северной Америки.

Jo Macfarlane

Swine flu jab link to killer nerve disease: Leaked letter reveals concern of neurologists over 25 deaths in America

Daily Mail, 15 August 2009, 21:29 BST,
http://www.dailymail.co.uk/news/article-1206807/Swine-flu-jab-link-killer-nerve-disease-Leaked-letter-reveals-concern-neurologists-25-deaths-America.html

A warning that the new swine flu jab is linked to a deadly nerve disease has been sent by the Government to senior neurologists in a confidential letter.

The letter from the Health Protection Agency, the official body that oversees public health, has been leaked to The Mail on Sunday, leading to demands to know why the information has not been given to the public before the vaccination of millions of people, including children, begins.

It tells the neurologists that they must be alert for an increase in a brain disorder called Guillain-Barre Syndrome (GBS), which could be triggered by the vaccine.

GBS attacks the lining of the nerves, causing paralysis and inability to breathe, and can be fatal.
The letter, sent to about 600 neurologists on July 29, is the first sign that there is concern at the highest levels that the vaccine itself could cause serious complications.

It refers to the use of a similar swine flu vaccine in the United States in 1976 when:

- **More people** died from the vaccination than from swine flu.
- 500 cases of **GBS** were detected.
- The vaccine may **have increased the risk** of contracting GBS by eight times.
- The vaccine **was withdrawn** after just ten weeks when the link with GBS became clear.
- The **US Government was forced to pay** out millions of dollars to those affected.

Concerns have already been raised that the new vaccine has not been sufficiently tested and that the effects, especially on children, are unknown.
It is being developed by pharmaceutical companies and will be given to about 13million people during the first wave of immunisation, expected to start in October.

Top priority will be given to everyone aged six months to 65 with an underlying health problem, pregnant women and health professionals.
The British Neurological Surveillance Unit (BNSU), part of the British Association of Neurologists, has been asked to monitor closely any cases of GBS as the vaccine is rolled out.
One senior neurologist said last night: ‘I would not have the swine flu jab because of the GBS risk.’
There are concerns that there could be a repeat of what became known as the ‘1976 debacle’ in the US, where a swine flu vaccine killed 25 people – more than the virus itself.
A mass vaccination was given the go-ahead by President Gerald Ford because scientists believed that the swine flu strain was similar to the one responsible for the 1918-19 pandemic, which killed half a million Americans and 20million people worldwide.

The swine flu vaccine being offered to children has not been tested on infants

Within days, symptoms of GBS were reported among those who had been immunised and 25 people died from respiratory failure after severe paralysis. One in 80,000 people came down with the condition. In contrast, just one person died of swine flu.

More than 40million Americans had received the vaccine by the time the programme was stopped after ten weeks. The US Government paid out millions of dollars in compensation to those affected.

The swine flu virus in the new vaccine is a slightly different strain from the 1976 virus, but the possibility of an increased incidence of GBS remains a concern.

Shadow health spokesman Mike Penning said last night: ‘The last thing we want is secret letters handed around experts within the NHS. We need a vaccine but we also need to know about potential risks.

‘Our job is to make sure that the public knows what’s going on. Why is the Government not being open about this? It’s also very worrying if GPs, who will be administering the vaccine, aren’t being warned.’

Two letters were posted together to neurologists advising them of the concerns.

The first, dated July 29, was written by Professor Elizabeth Miller, head of the HPA’s Immunisation Department.

It says: ‘The vaccines used to combat an expected swine influenza pandemic in 1976 were shown to be associated with GBS and were withdrawn from use. ‘GBS has been identified as a condition needing enhanced surveillance when the swine flu vaccines are rolled out. ‘Reporting every case of GBS irrespective of vaccination or disease history is essential for conducting robust epidemiological analyses capable of identifying whether there is an increased risk of GBS in defined time periods after vaccination, or after influenza itself, compared with the background risk.’

The second letter, dated July 27, is from the Association of British Neurologists and is written by Dr Rustam Al-Shahi Salman, chair of its surveillance unit, and Professor Patrick Chinnery, chair of its clinical research committee.

It says: ‘Traditionally, the BNSU has monitored rare diseases for long periods of time. However, the swine influenza (H1N1) pandemic has overtaken us and we need every member’s involvement with a new BNSU survey of Guillain-Barre Syndrome that will start on August 1 and run for approximately nine months.

‘Following the 1976 programme of vaccination against swine influenza in the US, a retrospective study found a possible eight-fold increase in the incidence of GBS.

‘Active prospective ascertainment of every case of GBS in the UK is required. Please tell BNSU about every case. You will have seen Press coverage describing the Government’s concern about releasing a vaccine of unknown safety. If there are signs of a rise in GBS after the vaccination programme begins, the Government could decide to halt it.

GBS attacks the lining of the nerves, leaving them unable to transmit signals to muscles effectively.

It can cause partial paralysis and mostly affects the hands and feet. In serious cases, patients need to be kept on a ventilator, but it can be fatal.

Death is caused by paralysis of the respiratory system, causing the victim to suffocate. It is not known exactly what causes GBS and research on the subject has been inconclusive.

However, it is thought that one in a million people who have a seasonal flu vaccination could be at risk and it has also been linked to people recovering from a bout of flu of any sort.

The HPA said it was part of the Government’s pandemic plan to monitor GBS cases in the event of a mass vaccination campaign, regardless of the strain of flu involved. But vaccine experts warned that the letters proved the programme was a ‘guinea-pig trial’.

Dr Tom Jefferson, co-ordinator of the vaccines section of the influential Cochrane Collaboration, an independent group that reviews research, said: 'New vaccines never behave in the way you expect them to. It may be that there is a link to GBS, which is certainly not something I would wish on anybody. 'But it could end up being anything because one of the additives in one of the vaccines is a substance called squalene, and none of the studies we've extracted have any research on it at all.'

He said squalene, a naturally occurring enzyme, could potentially cause so-far-undiscovered side effects.

Jackie Fletcher, founder of vaccine support group Jabs, said: 'The Government would not be anticipating this if they didn't think there was a connection. What we've got is a massive guinea-pig trial.'

Professor Chinnery said: 'During the last swine flu pandemic, it was observed that there was an increased frequency of cases of GBS. No one knows whether it was the virus or the vaccine that caused this. 'The purpose of the survey is for us to assess rapidly whether there is an increase in the frequency of GBS when the vaccine is released in the UK. It also increases consultants' awareness of the condition.

Panic over? The number of swine flu cases has fallen sharply in the past few weeks

'This is a belt-and-braces approach to safety and is not something people should be substantially worried about as it's a rare condition.'

If neurologists do identify a case of GBS, it will be logged on a central database.

Details about patients, including blood samples, will be collected and monitored by the HPA.

It is hoped this will help scientists establish why some people develop the condition and whether it is directly related to the vaccine.

But some question why there needs to be a vaccine, given the risks. Dr Richard Halvorsen, author of The Truth About Vaccines, said: 'For people with serious underlying health problems, the risk of dying from swine flu is probably greater than the risk of side effects from the vaccine.

'But it would be tragic if we repeated the US example and ended up with more casualties from the jabs. 'I applaud the Government for recognising the risk but in most cases this is a mild virus which needs a few days in bed. I'd question why we need a vaccine at all.'

Professor Miller at the HPA said: 'This monitoring system activates pandemic plans that have been in place for a number of years. We'll be able to get information on whether a patient has had a prior influenza illness and will look at whether influenza itself is linked to GBS.

'We are not expecting a link to the vaccine but a link to disease, which would make having the vaccine even more important.'

The UK's medicines watchdog, the Medicines and Healthcare Products Regulatory Agency, is already monitoring reported side effects from Tamiflu and Relenza and it is set to extend that surveillance to the vaccine.

A Department of Health spokesperson said: 'The European Medicines Agency has strict processes in place for licensing pandemic vaccines.

'In preparing for a pandemic, appropriate trials to assess safety and the immune responses have been carried out on vaccines very similar to the swine flu vaccine. The vaccines have been shown to have a good safety profile.

'It is extremely irresponsible to suggest that the UK would use a vaccine without careful consideration of safety issues. The UK has one of the most successful immunisation programmes in the world.'

I couldn''t eat or speak... It was horrendous –

Victim: Hilary Wilkinson spent three months in hospital after she was diagnosed with Guillain-Barre Syndrome ...

When Hilary Wilkinson woke up with muscle weakness in her left arm and difficulty breathing, doctors initially put it down to a stroke. But within hours, she was on a ventilator in intensive care after being diagnosed with Guillain-Barre Syndrome.

She spent three months in hospital and had to learn how to talk and walk again. But at times, when she was being fed through a drip and needed a tracheotomy just to breathe, she doubted whether she would survive.

The mother of two, 57, from Maryport, Cumbria, had been in good health until she developed a chest infection in March 2006. She gradually became so weak she could not walk downstairs.

Doctors did not diagnose Guillain-Barre until her condition worsened in hospital and tests showed her reflexes slowing down. It is impossible for doctors to know how she contracted the disorder, although it is thought to be linked to some infections.

Mrs Wilkinson said: ‘It was very scary. I couldn’t eat and I couldn’t speak. My arms and feet had no strength and breathing was hard.

I was treated with immunoglobulin, which are proteins found in blood, to stop damage to my nerves. After ten days, I still couldn’t speak and had to mime to nurses or my family.

‘It was absolutely horrendous and I had no idea whether I would get through it. You reach very dark moments at such times and wonder how long it can last.

But I’m a very determined person and I had lots of support.’

After three weeks, she was transferred to a neurological ward, where she had an MRI scan and nerve tests to assess the extent of the damage.

Still unable to speak and in a wheelchair, Mrs Wilkinson eventually began gruelling physiotherapy to improve her muscle strength and movement but it was exhausting and painful.

Three years later, she is almost fully recovered. She can now walk for several miles at a time, has been abroad and carries out voluntary work for a GBS Support Group helpline.

She said: ‘It makes me feel wary that the Government is rolling out this vaccine without any clear idea of the GBS risk, if any. I wouldn’t wish it on anyone and it certainly changed my life.

‘I’m frightened to have the swine flu vaccine if this might happen again – it’s a frightening illness and I think more research needs to be done on the effect of the vaccine.’

Hotline staff given access to confidential records

Confidential NHS staff records and disciplinary complaints could be accessed by hundreds of workers manning the Government’s special swine flu hotline.

They were able to browse through a database of emails containing doctors’ and nurses’ National Insurance numbers, home addresses, dates of birth, mobile phone numbers and scanned passport pages – all details that could be used fraudulently.

And private and confidential complaints sent by hospitals about temporary medical staff – some of whom were named – were also made available to the call-centre workers, who were given a special password to log in to an internal NHS website.

It could be a breach of the Data Protection Act.

The hotline staff work for NHS Professionals, which was set up using taxpayers’ money to employ temporary medical and administrative staff for the health service.

The not-for-profit company runs two of the Government's swine flu call centres – with 300 staff in Farnborough, Hampshire, and 900 in Watford, Hertfordshire.

Shadow Health Secretary Andrew Lansley described the revelations as 'disturbing'.

Anne Mitchell, a spokeswoman for Unison, said: 'There's no excuse for such a fundamental breach of personal security. Action needs to be taken as soon as possible to make sure this does not happen again.'

A spokeswoman for NHS Professionals would not confirm whether access to the confidential files had been granted.

THE TIMES

Health Officials Warn of H1N1 Vaccine's Link to Deadly Nerve Disease

The Times, London, 16 August 2009
https://web.archive.org/web/20090904022432/http://www.foxnews.com/story/0,2933,539880,00.html
https://web.archive.org/web/20091108090613/http://www.timesonline.co.uk/tol/news/uk/health/Swine_flu/article6797993.ece

Hartford, Conn. – British health officials have warned doctors of possible similarities between the new H1N1 vaccine and a shot linked to 25 deaths in the U.S. in the 1970s.

The British government's Health Protection Agency (HPA), said in a letter to neurologists that they needed to look out for increases in cases of a brain disorder that might follow the launch of the immunization program.

The letter has been sent because of concerns sparked by studying of the swine flu vaccination campaign in the U.S.

In 1976, Washington rushed in a mass immunization program against a similar swine flu outbreak that was confined to a single military base.

Several hundred cases of a rare, lethal, paralyzing neurological disease called Guillain-Barré syndrome (GBS) were reported afterwards, and although no clear link was ever found to the vaccine, the incident made many mistrustful of immunizations.

Although the swine flu virus vaccine now close to completion is different from the one used in 1976, the HPA said the earlier incident nevertheless highlighted a possible area of concern.

"The vaccines used to combat an expected swine influenza pandemic in 1976 were shown to be associated with GBS and were withdrawn from use," Professor Elizabeth Miller, head of the HPA's immunisation department, wrote in the letter sent last month to neurologists.

"GBS has been identified as a condition needing enhanced surveillance when the swine flu vaccines are rolled out."

The Department of Health said: "Appropriate trials to assess safety and immune responses have been carried out on vaccines very similar to the swine flu vaccine. The vaccines have been shown to have a good safety profile."

The World Health Organisation has also said recently that the public should be "reassured" about the safety of the new vaccine. It acknowledged that "genuine adverse events directly caused by the vaccine may also occur, but cannot be predicted in advance".

The NHS will monitor any possible risks from the vaccine, including a possible connection with GBS.

GlaxoSmithKline is developing the vaccine in Germany for an immunisation programme due to start in October.

Some 9.4m people in England will receive the vaccine if they fall into priority groups, alongside 2.1m frontline health and social care workers. In Scotland 1.4m people in either at-risk groups or working in health and social care will get the jab.

Priority will be given to those aged six months to 65 years in high-risk groups – including those with asthma, diabetes, heart disease, renal disease or with a compromised immune system.

THE FLU CASE

Side effects of influenza vaccines
Report in Chinese on the "swine flu" jab risks

The Flu Case, 9 September 2009
https://web.archive.org/web/20090917131846/http://www.theflucase.com/index.php?option=com_content&view=article&id=535%3Areport-in-chinese-on-the-qswine-fluq-jab-risks&catid=1%3Alatest-news&Itemid=64&lang=en

Even influenza vaccines that do not contain squalene based adjuvants can cause side effects. CSL's seasonal influenza vaccine for winter 2009, "Fluvax", for example. Adverse reactions to the vaccine (according to the manufacturer's data sheet) include:

"Blood and Lymphatic System Disorders
Rare: Transient thrombocytopenia.

Immune System Disorders
Rare: Allergic reactions including anaphylactic shock.

Nervous System Disorders
Rare: Neuralgia, paraesthesia and convulsions.
Very rare: Encephalopathy, neuritis or neuropathy and Guillain-Barré syndrome.

Vascular Disorders
Very rare: Vasculitis with transient renal involvement.

Skin and Subcutaneous Tissue Disorders
Uncommon: Pruritus, urticaria and rash.

General Disorders and Administration Site Conditions
Very Common: Injection site inflammation.

Common: Influenza-like illness, Injection site ecchymosis and induration
Influenza-like illness may include pyrexia, chills, headache, malaise and myalgia.

Adverse event frequencies are defined as follows: Very common (≥ 1/10), common (≥ 1/100, < 1/10), uncommon (≥ 1/1,000, < 1/100), rare (≥ 1/10,000, < 1/1,000) and very rare (< 1/10,000)."

It is worth noting that according to the Datasheet, "Fluvax" does not contain either aluminium adjuvant or the mercury based preservative thimerosal (thiomersal). Influenza vaccines that do contain these ingredients could be reasonably expected to cause more serious side effects. =>

MERCOLA
Take Control of Your Health

Joseph Mercola

Flu Vaccine Exposed
Mercola, 26 September 2009
https://www.omeonet.info/articles/flu_vaccine.htm

Studies show that flu vaccines are unsafe and ineffective. This presentation by the Thinktwice Global Vaccine Institute includes a visual depiction of flu vaccine production - how the flu vaccine is made and what it contains.

Signs and Symptoms of Influenza

As most of you probably know, influenza is a contagious viral respiratory infection. Symptoms include:

- Fever
- Chills
- Runny nose
- Sore throat
- Cough
- Muscle aches
- Fatigue
- Decreased appetite

Mercola.com
https://articles.mercola.com › sites › archive › 2009/09/26
Flu Vaccine Exposed: How Effective Is ...
26 Sept 2009 — Mercola's latest position on any health topic. Studies **show that flu vaccines are unsafe and ineffective**. This presentation by the Thinktwice ...

Typically, the condition will improve after two to three days of bed rest, although some symptoms may persist for about a week. What many people do NOT know, however, is that death caused directly by the flu virus is very rare. The vast majority of so-called "flu deaths" are in fact due to bacterial pneumonia – a potential complication of the flu if your immune system is too weak. Other complications can include ear- or sinus infections, dehydration, and worsening of chronic health conditions.

The elderly and people with other pre existing medical conditions such as asthma, diabetes, or heart disease, are at higher risk of developing pneumonia after a bout of the flu. The Flu Vaccine does not Prevent the Flu, nor Protect Against the Vast Majority of Flu-Related Deaths.

The conventional treatment for bacterial pneumonia is an antibiotic, not a viral flu drug, so to think that taking a flu vaccine will prevent death from pneumonia doesn't really make sense.

"But the vaccine will prevent the flu, which will prevent the possibility of developing pneumonia," some might say.

That sounds good in theory, but the statistics simply do not support this assertion.

Because study after study, and master studies that compile the results from several studies to get a more objective result, keep coming to the same conclusion: Flu vaccines *do not work*, and in many cases do more harm than good. In fact, one shocking statistic brought to light in this video is that before the CDC advocated vaccinating children under the age of five, the number of children dying from the flu was very low, and on the decline.

Then, in 2003, just after children aged five and under started getting vaccinated, the number of flu deaths skyrocketed. The death toll was enormous compared to the previous year, when the flu vaccine was not administered en masse to that age group! How anyone can consider a strategy that yields a higher death toll to be a "success" is a mystery to me.

The Problem with Flu Death Statistics

However, as frightening as much of this may sound, it's important to keep things in perspective. According to the statistics shown in the video above, more Americans die from asthma, and even malnutrition each year, than the flu.

Unfortunately, the Centers for Disease Control and Prevention (CDC) grossly distort the facts about flu deaths, making the flu virus seem far more dangerous than is warranted. On the CDC's main flu page, they state that about 36,000 people die from the flu in the United States each year. But if you search a little harder, you can find the actual number of people who died from the flu in 2005 (this is the most recent data that's available) was 1,806. The remainder was caused by pneumonia. In 2004, there were just 1,100 actual flu deaths. The statistics the CDC gives are skewed partly because they classify those dying from pneumonia as dying from the flu, which is inaccurate.

How is the Flu Vaccine Made?

This is another area that many people do not understand or take into consideration before getting a seasonal flu shot.

In January or February of each year, health authorities travel to Asia to determine which strains of the flu are currently active. Based on their findings in Asia, they assume that the same strains of viruses will spread to the U.S. by fall.

At this point, U.S. vaccine manufacturers start making that season's flu vaccine, which will contain the strains found in Asia. However, if the viral strains circulating in the U.S. that season are not identical to those in Asia, the vaccine you receive is a complete dud. And to add insult to injury, you've just been injected with a laundry list of harmful ingredients.

What's in the Seasonal Flu Vaccine?

The flu strains selected are cultivated in chick embryos for several weeks before being inactivated with formaldehyde, which is a known cancer-causing agent. Then they're preserved with thimerosal, which is 49 percent mercury by weight.

Even many health care professionals are confused about this and are not aware that the preservative thimerosal is mercury. As a quick side note, one of my chief writers told me that, "the doctor's office told me the vaccine does not contain mercury, just something called thimerosal."

Please, don't be fooled by this incredible ignorance. If you have carefully studied this issue there is a great possibility you may know more than your physician about this topic. Don't back down if they tell you something you otherwise know to be true.

According to the CDC, the majority of flu vaccines contain thimerosal. Some contain as much as 25 mcg of mercury per dose. This means that it may contain more than 250 times the Environmental Protection Agency's safety limit for mercury. By now, most people are well aware that children and fetuses are most at risk of damage from this neurotoxin, as their brains are still developing. Yet the CDC still recommends that children over 6 months, and pregnant women, receive the flu vaccine each year.

In addition to mercury, flu vaccines also contain other toxic or hazardous ingredients like:

Aluminum -- a neurotoxin that has been linked to Alzheimer's disease
Triton X-100 -- a detergent
Phenol (carbolic acid)
Ethylene glycol (antifreeze)
Betapropiolactone - a disinfectant
Nonoxynol - used to kill or stop growth of STDs
Octoxinol 9 - a vaginal spermicide
Sodium phosphate

How Safe is the Flu Vaccine? *Serious reactions* to the flu vaccine include, but are not limited to:
Life-threatening allergies to various ingredients
Guillain-Barre Syndrome (a severe paralytic disease that is fatal in about 1 in 20 cases)
Encephalitis (brain inflammation)
Neurological disorders
Thrombocytopenia (a serious blood disorder)

How Effective is the Flu Vaccine?
Remember that the potential effectiveness of a flu vaccine is dependent on the ASSUMPTION, made nearly a year in advance, that Asia's viral strains will be the ones hitting the U.S. When they guess wrong, the vaccine is worthless from the very start.
But does that mean they withdraw the flu vaccine when they discover it contains the wrong strains? NO! They just keep giving it out anyway.

But even if they were to overcome that hurdle and actually select the correct strains, there's still no evidence that it does anyone any good to get a flu vaccine. Study after study comes back showing the same dismal results: the flu vaccines are not an effective method of prevention of the flu, and they do not save lives. As mentioned earlier, they may even be responsible for an increased death rate in some groups. Sometimes determining efficacy is as easy as reading the information coming straight from the vaccine manufacturer.

How about this quote taken directly from the flu vaccine FLULAVAL's package insert (which you likely never see when getting the flu shot) for the 2009-2010 formula:
"FLULAVAL is an influenza virus vaccine indicated for active immunization of adults 18 years of age and older against influenza disease caused by influenza virus subtypes A and type B contained in the vaccine. This indication is based on immune response elicited by FLULAVAL, and there have been *no controlled trials* demonstrating a decrease in influenza disease after vaccination with FLULAVAL."

That's right, NO controlled trials demonstrating ANY decrease in your risk of contracting the flu at all after vaccination! (It also states that each dose contains a total of 25 mcg of mercury.)

For those of you who are still unconvinced, know that there's plenty of scientific evidence available to back up the recommendation to avoid flu vaccines. In addition to studies mentioned in the video, here are several other examples showing that flu vaccines do not work for any age group:
A study published in the October 2008 issue of the Archives of Pediatric & Adolescent Medicine found that vaccinating young children against the flu had no impact on flu-related hospitalizations or doctor visits during two recent flu seasons. The researchers concluded that "*significant influenza vaccine effectiveness could not be demonstrated* for any season, age, or setting" examined.
See => doi: 10.1001/archpedi.162.10.943. PMID: 18838647

A 2008 study published in the Lancet found that influenza vaccination was NOT associated with a reduced risk of pneumonia in older people. This supports an earlier study, published in The New England Journal of Medicine. Research published in the American Journal of Respiratory and Critical Care Medicine also confirms that there has been no decrease in deaths from influenza and pneumonia in the elderly, despite the fact that vaccination coverage among the elderly has increased from 15 percent in 1980 to 65 percent now.

In 2007, researchers with the National Institute of Allergy and Infectious Diseases, and the National Institutes of Health published this conclusion in the Lancet Infectious Diseases: "We conclude that frailty selection bias and use of non-specific endpoints such as all-cause mortality,have led cohort studies to greatly exaggerate vaccine benefits."
=> https://pubmed.ncbi.nlm.nih.gov/17897608/

A large-scale, systematic review of 51 studies, published in the Cochrane Database of Systematic Reviews in 2006, found no evidence that the flu vaccine is any more effective than a placebo in children. The studies involved 260,000 children, age 6 to 23 months.

Last but not least, I think it says a lot that 70 percent of *doctors and nurses*, and 62 percent of other health care workers *do not get the yearly flu shot*. The reasons why they opted to not get vaccinated were:

- They didn't believe the vaccine would work
- They believed their immune systems were strong enough to withstand exposure to the flu
- They were concerned about side effects
- Might Influenza be little more than a symptom of Vitamin D deficiency?

Vitamin D, "the sunshine vitamin," may very well be one of the most beneficial vitamins there is for disease prevention. Unfortunately it's also one of the vitamins that a vast majority of people across the world are deficient in due to lack of regular exposure to sunshine. Published in the journal Epidemiology and Infection in 2006, the hypothesis presented by Dr. John Cannell and colleagues in the paper Epidemic Influenza and Vitamin D raises the possibility that influenza is a symptom of vitamin D deficiency. The vitamin D formed when your skin is exposed to sunlight regulates the expression of more than 2,000 genes throughout your body, including ones that influence your immune system to attack and destroy bacteria and viruses. Hence, being overwhelmed by the "flu bug" could signal that your vitamin D levels are too low, allowing the flu virus to overtake your immune system.

At least five studies show an inverse association between lower respiratory tract infections and 25(OH)D levels. That is, the higher your vitamin D level, the lower your risk of contracting colds, flu, and other respiratory tract infections. A 2007 study suggests higher vitamin D status enhances your immunity to microbial infections. They found that subjects with vitamin D deficiency had significantly more days of absence from work due to respiratory infection than did control subjects.

A 2009 study on vitamin D deficiency in newborns with acute lower respiratory infection (ALRI) confirmed a strong, positive correlation between newborns' and mother's vitamin D levels. Over 87 percent of all newborns and over 67 percent of all mothers had vitamin D levels lower than 20 ng/ml, which is a severe deficiency state. Newborns with vitamin D deficiency appear to have an increased risk of developing ALRI, and since the child's vitamin D level strongly correlates with its mother's, the researchers recommend that all mothers' optimize their vitamin D levels during pregnancy, especially in the winter months, to safeguard their baby's health. A similar Indian study published in 2004 also reported that vitamin D deficiency in infants significantly raised their odds ratio for having severe ALRI.

A 2009 analysis of the Third National Health andNutrition Examination Survey examined the association between vitamin D levelsand recent upper respiratory tract infection (URTI) in nearly 19,000 subjects over the age of 12. Recent URTI was reported by:

17 percent of participants with vitamin D levels of 30ng/ml or higher
20 percent of participants with vitamin D levels between 10-30 ng/ml.
24 percent of participants with vitamin D levels below 10ng/ml
The positive correlation between lower vitamin D levels and increased risk of URTI was even stronger in individuals with asthma and chronic obstructive pulmonary disease.

Another 2009 report in the journal Pediatric Research stated that infants and children appear more susceptible to viral rather than bacterial infections when deficient in vitamin D. And that, based on the available evidence showing a strong connection between vitamin D, infections, and immune function in children, vitamin D supplementation may be a valuable therapy in pediatric medicine.

How to Prevent the Flu without Getting a Flu Shot

For most people the flu shot does not make you healthy; it does just the opposite and weakens your immune system. If you follow a healthy lifestyle, you will not have to worry about getting the flu. Take it from me – I've never received a flu shot, and I haven't missed a day of work due to illness in over 20 years. The key steps that I follow to stay flu-free, which I suggest you follow too, include: Get plenty of sunshine, safe tanning bed exposure or supplemental vitamin D3; Eat right for your nutritional type, including avoiding sugar; Exercise; Get adequate sleep; Address emotional stress, ...

Study prompts provinces to rethink flu plan
Report suggests people who get vaccinated are more likely to catch H1N1

The Globe and Mail, 30 September 2009, 01:44 PM EDT
https://web.archive.org/web/20091001110114/https://www.theglobeandmail.com/news/technology/science/study-prompts-provinces-to-rethink-flu-plan/article1303330/

A "perplexing" Canadian study linking H1N1 to seasonal flu shots is throwing national influenza plans into disarray and testing public faith in the government agencies responsible for protecting the nation's health.

Distributed for peer review last week, the study confounded infectious-disease experts in suggesting that people vaccinated against seasonal flu are twice as likely to catch swine flu.

The paper is under peer review, and lead researchers Danuta Skowronski of the British Columbia Centre for Disease Control and Gaston De Serres of Laval University must stay mum until it's published.

Met with intense early skepticism both in Canada and abroad, the paper has since convinced several provincial health agencies to announce hasty suspensions of seasonal flu vaccinations, long-held fixtures of public-health planning.

"It has confused things very badly," said Dr. Ethan Rubinstein, head of adult infectious diseases at the University of Manitoba. "And it has certainly cost us credibility from the public because of conflicting recommendations. Until last week, there had always been much encouragement to get the seasonal flu vaccine."

On Sunday Quebec joined Alberta, Saskatchewan, Ontario and Nova Scotia in suspending seasonal flu shots for anyone under 65 years of age. Quebec's Health Ministry announced it would postpone vaccinations until January, clearing the autumn months for health professionals to focus on vaccinating against H1N1, which is expected to the more severe influenza strain this season.

"By the time the H1N1 wave is over, there will be ample time to vaccinate for seasonal flu," Dr. Rubinstein said.

B.C. is expected to announce a similar suspension during a press conference Monday morning.

Other provinces, including Manitoba, are still pondering a response to the research.

New Brunswick is a lone hold-out, announcing last week it would forge ahead with seasonal flu shots for all residents in October, as originally planned.

So far, the study's impact is confined to Canada. Researchers in the U.S., Britain and Australia have not reported the same phenomenon. Marie-Paule Kieny, the World Health Organization's director of vaccine research, said last week the Canadian findings were an international anomaly and could constitute a "study bias."

An international panel is currently scrutinizing the research data. "The review process has been expedited, so we're hoping for a response within days," said Roy Wadia, spokesman for the B.C. Centre for Disease Control.

Dr. Rubinstein, who has read the study, said it appears sound.

"There are a large number of authors, all of them excellent and credible researchers," he said. "And the sample size is very large – 12 or 13 million people taken from the central reporting systems in three provinces. The research is solid."

The vaccine suspensions do not apply for people over 65. Seniors are considered more susceptible to severe seasonal flu symptoms. At the same time, they carry antibodies from a 1957 pandemic that seem to neutralize the current version of H1N1.

Even if the statistical link is proven, the medical link between seasonal flu shots and H1N1 remains mysterious. One hypothesis suggests seasonal flu vaccine preoccupies the cells that would otherwise produce antibodies against H1N1.

But, according to Dr. Rubinstein, the research shows that people who received the seasonal shot during the 2007-08 flu season remained vulnerable to swine flu well into 2009 – an interval that should provide most immune systems ample restoration time.

"We don't understand the mechanism," Dr. Rubinstein said. "At the present time it is quite perplexing."

Presumably, they refer to the following studies:

Skowronski DM, De Serres G, Crowcroft NS, et al.
Association between the 2008-09 seasonal influenza vaccine and pandemic H1N1 illness during Spring-Summer 2009: four observational studies from Canada. PLoS Med. 2010 Apr 6;7(4):e1000258. doi: 10.1371/journal.pmed.1000258. PMID: 20386731; PMCID: PMC2850386.

Abstract
Background: In late spring 2009, concern was raised in Canada that prior vaccination with the 2008-09 trivalent inactivated influenza vaccine (TIV) was associated with increased risk of pandemic influenza A (H1N1) (pH1N1) illness. Several epidemiologic investigations were conducted through the summer to assess this putative association.

Studies included: (1) test-negative case-control design based on Canada's sentinel vaccine effectiveness monitoring system in British Columbia, Alberta, Ontario, and Quebec; (2) conventional case-control design using population controls in Quebec; (3) test-negative case-control design in Ontario; and (4) prospective household transmission (cohort) study in Quebec. Logistic regression was used to estimate odds ratios for TIV effect on community- or hospital-based laboratory-confirmed seasonal or pH1N1 influenza cases compared to controls with restriction, stratification, and adjustment for covariates including combinations of age, sex, comorbidity, timeliness of medical visit, prior physician visits, and/or health care worker (HCW) status. For the prospective study risk ratios were computed. Based on the sentinel study of 672 cases and 857 controls, 2008-09 TIV was associated with statistically significant protection against seasonal influenza (odds ratio 0.44, 95% CI 0.33-0.59). In contrast, estimates from the sentinel and three other observational studies, involving a total of 1,226 laboratory-confirmed pH1N1 cases and 1,505

controls, indicated that prior receipt of 2008-09 TIV was associated with increased risk of medically attended pH1N1 illness during the spring-summer 2009, with estimated risk or odds ratios ranging from 1.4 to 2.5. Risk of pH1N1 hospitalization was not further increased among vaccinated people when comparing hospitalized to community cases.

Conclusions: Prior receipt of 2008-09 TIV was associated with increased risk of medically attended pH1N1 illness during the spring-summer 2009 in Canada. The occurrence of bias (selection, information) or confounding cannot be ruled out. Further experimental and epidemiological assessment is warranted. Possible biological mechanisms and immunoepidemiologic implications are considered.

Janjua NZ, Skowronski DM, Hottes TS, et al.

Seasonal influenza vaccine and increased risk of pandemic A/H1N1 - related illness: first detection of the association in British Columbia, Canada. Clin Infect Dis. 2010 Nov 1;51 (9): 1017-27. doi: 10.1086/656586. PMID: 20887210; PMCID: PMC7107856.

Abstract

Background: In April 2009, an elementary school outbreak of pandemic H1N1 (pH1N1) influenza was reported in a community in northern British Columbia, Canada--an area that includes both non-Aboriginal and Aboriginal residents living on or off a reserve. During the outbreak investigation, we explored the relationship between prior receipt of trivalent inactivated influenza vaccine (TIV) and pH1N1-related illness.

Methods: A telephone survey was conducted from 15 May through 5 June 2009 among households of children attending any school in the affected community. Members of participating households where influenza-like illness (ILI) was described were then invited to submit blood samples for confirmation of pH1N1 infection by hemagglutination inhibition and microneutralization assays. Circulation of pH1N1 was concentrated among households of the elementary school and elsewhere-reserve to which analyses of TIV effect were thus restricted. Odds ratios (ORs) for the TIV effect on ILI were computed through logistic regression, with adjustment for age, comorbidity, household density, and Aboriginal status. The influence of within-household clustering was assessed through generalized-linear-mixed models.

Results: Of 408 participants, 92 (23%) met ILI criteria: 29 (32%) of 92 persons with ILI, compared with 61 (19%) 316 persons without ILI, had received the 2008-2009 formulation of TIV. Fully adjusted ORs for 2008-2009 TIV effect on ILI were 2.45 (95% confidence interval, 1.34-4.48) by logistic regression and 2.68 [95% confidence interval, 1.37-5.25) by generalized-linear-mixed model.

Conclusions: An outbreak investigation in British Columbia during the late spring of 2009 provided the first indication of an unexpected association between receipt of TIV and pH1N1 illness. This led to 5 additional studies through the summer 2009 in Canada, each of which corroborated these initial

Grippe A: un Français sur deux allergique au vaccin

28 septembre 2009 à 2h0
https://www.slate.fr/story/10861/grippe-un-francais-sur-deux-allergique-au-vaccin

Le gouvernement est confronté à une résistance vaccinale qu'il n'avait pas anticipée.

A-t-on jamais vu, en France, une situation à ce point paradoxale dans l'histoire de la médecine et de la santé publique? Résumons. Une pandémie grippale est annoncée depuis près de cinq mois. A Paris comme dans de nombreuses autres capitales des pays industriels les autorités sanitaires réactivent un plan de lutte contre une autre pandémie d'origine aviaire; une pandémie potentiellement redoutable, mais qui fort heureusement est pour l'heure restée dans les limbes. Le gouvernement de François Fillon décide de placer la barre préventive le plus haut possible et, notamment, de passer commande (pour environ un milliard d'euros) de près de cent millions de doses du futur vaccin contre l'infection causée par le nouveau virus A(H1N1). Objectif: disposer coûte que coûte d'un stock qui permettra, au total, de pouvoir immuniser la totalité de la population française.

Les multinationales concernées se lancent dans une course-poursuite sans précédent pour livrer au plus tôt l'outil protecteur en France comme dans tous les pays industriels qui, en urgence, leur en ont fait la demande. Dans l'Hexagone, à la demande des pouvoirs publics des dizaines d'éminents spécialistes se réunissent durant des jours et des nuits pour savoir qui pourra être vacciné en priorité. Conclaves successifs pour concilier au mieux santé publique, organisation sociale et principes éthiques.

Nous vécûmes l'été à ce rythme. Puis nous voici désormais fin septembre; ces millions de doses vaccinales vont sous peu commencer à être livrées, de multiples centres spécialisés dans cette vaccination spécifique vont devoir bientôt sortir de terre. Puis, brutalement ce tout récent sondage de l'Ifop selon lequel seul un Français sur deux (55%), déclare avoir l'intention de se faire vacciner contre la nouvelle grippe. Plus précisément seuls 29% expliquent qu'ils se «soumettront certainement» à cette prochaine vaccination. Et, sans doute plus étonnant encore: ces proportions sont respectivement de 61% et 38% chez les médecins généralistes?

Un sondage Ifop-«le Quotidien du Médecin» confirme les réticences des médecins exerçant dans le secteur libéral: 46% d'entre eux n'envisagent pas de se vacciner quand 52% indiquent qu'ils seront prêts, le moment venu, à le faire. Un généraliste sur deux réticent à l'immunisation, en somme. Pourquoi pas plus? Que répondront tous les praticiens choisissant de ne pas se faire vacciner à leurs patients qui leur demanderont conseil? D'autres sondages (TNS Sofres/Logica pour Europe 1) évoquent 65% de refus potentiels à la vaccination dans la population générale.

Quelles que soient les proportions exactes de refus et d'acceptation le fait est là: il existe en France une forme de résistance collective potentielle à la vaccination sur laquelle le pouvoir public n'avait pas tablé. Cette situation à la fois inédite et largement problématique fait que l'on phosphore aujourd'hui à très fortes doses dans les hautes sphères sanitaires et gouvernementales françaises. Questions, au choix. A-t-on eu raison d'effectuer de telles commandes vaccinales? Avait-on pris le pouls de l'opinion avant de prendre cette décision? Si oui qui l'a pris? Si non, pourquoi? N'aurait-il pas été plus judicieux de patienter? Fallait-il laisser à chacun la liberté d'agir? Aurait-on dû au contraire imposer coûte que coûte une obligation vaccinale aux professionnels de santé dont on estime (à juste titre) qu'il convient de les protéger pour eux-mêmes autant que pour ceux qu'ils sont amenés à prendre en charge?

Convaincre en somme, faute d'avoir imposé. François Fillon, il y a quelques jours, à l'issue d'un conseil interministériel consacré à ce sujet: *«Je veux rappeler que la vaccination* [contre la grippe A(H1N1] *n'est pas obligatoire, mais je fais appel à la responsabilité de chacun, et notamment, parce que c'est le plus important, à celle des personnels de santé. Nous avons besoin d'eux pour protéger l'ensemble des Français, nous avons donc besoin, naturellement, qu'ils soient vaccinés.*»

«Nous» avons besoin d'eux, certes; mais si «eux» ne répondent pas présents? En viendra-t-on (les textes existent) à l'injonction vaccinale? Sans doute pour mieux se faire comprendre M. Fillon a redit quelles étaient ici les priorités énoncées dans les recommandations du Haut Conseil de santé publique (HCSP): *«Le principe est simple,* a-t-il insisté*: les personnes prioritaires sont les personnes les plus vulnérables et ce sont les personnels de santé, parce que c'est naturellement sur eux que repose la santé de tous les autres.»* Plus précisément encore «prioritaires parmi les prioritaires»: les personnels de santé de réanimation, néonatale et pédiatrique, puis les personnels médical, paramédical et aide-soignant des établissements de santé, ainsi que les médecins et infirmiers exposés à des personnes infectées par le nouveau virus grippal.

Tout devrait ici être calé sur les volumes des livraisons progressives des doses vaccinales. Viendront ensuite les femmes enceintes puis les personnes de *«l'entourage des nourrissons de moins de 6 mois»*, les professionnels chargés de l'accueil de la petite enfance, les nourrissons de 6-23 mois avec facteur de risque, les sujets de 2 à 64 ans avec facteur de risque. Puis dans le grand ordonnancement jacobin, sanitaire et républicain: les autres professionnels de santé, les nourrissons de 6-23 mois sans facteur de risque, les personnels d'accueil des pharmacies, des personnels des établissements médico-sociaux. Enfin (vers le printemps?) les personnes de plus de 65 ans avec facteur de risque, les 2-18 ans sans facteur de risque et, pour finir (vers le prochain automne?) les personnes âgées de plus de 18 ans sans facteur de risque.

Tout cela est bel et beau mais repose, répétons-nous, sur le volontariat. Comment s'adaptera-t-on à la désaffection, désormais hautement prévisible, d'une fraction nullement négligeable des professionnels sanitaires officiellement désignés? Ministre de la santé chaque jour un peu plus confirmée - grâce à cette pandémie - dans ses fonctions Roselyne Bachelot ne cesse de rassurer: la technologie des vaccins est bien connue et les vaccins qui seront proposés auront *«évidemment satisfait à toutes les procédures de sécurité»*. L'OMS s'inscrit dans la même démarche incitatrice et rassurante, expliquant que *«les résultats des essais réalisés à cette date suggèrent que le vaccin pandémique est aussi sûr que les vaccins contre la grippe saisonnière, avec des effets secondaires «similaires». Mais qui aujourd'hui, sur fond d'anxiété diffuse et collective, est capable de préciser ce que sont ces «effets secondaires».*

Pour le reste la suite est d'ores et déjà annoncée. La France disposera sous peu d'environ un million de doses anti-A(H1N1), la multinationale britannique GlaxoSmithKline (GSK) ayant obtenu de l'agence européenne des médicaments les premières autorisations lui permettant de commercialiser son vaccin. Devraient ensuite arriver sur le marché les premières des 16 millions de doses commandées à Novartis. Plus précisément la France devrait disposer vers le 9 octobre de 1 à 1,2 million de doses de vaccins de GSK, les premières livraisons de Novartis dans l'Hexagone étant programmées fin octobre/début novembre. Les autres multinationales auxquelles la France a passé des commandes (Sanofi-Pasteur pour 28 millions de doses et Baxter) n'ont pas encore, pour diverses raisons, reçu l'aval des autorités européennes.

Quel usage précis sera fait de cette armada vaccinale sans précédent dans l'histoire de la grippe? Un premier élément de réponse nous est fourni par l'Ifop: «Malgré un discours médiatique anxiogène, la population française n'est pas gagnée par la peur de l'épidémie, nous assure l'Ifop. En juillet 2009, seuls 35% des Français se déclaraient inquiets. Le niveau d'inquiétude tend à décroître au fil des mois, en s'établissant à 32% en septembre, preuve que l'annonce des décès dus à la maladie (...) ne déclenche pas de crainte particulière au sein de la population hexagonale. A titre de comparaison, celle-ci ne se montre guère plus inquiète que lors de l'épidémie de grippe aviaire en 2006».

Dans le même temps, la menace de la grippe A(H1N1) est belle et bien devenue le premier sujet de conversation des Français, 80% d'entre eux l'ayant d'ores et déjà évoqué avec leurs proches. Faut-il y voir un paradoxe? Faut-il se souvenir (avant de la rappeler aux plus jeunes d'entre nous) de la fameuse histoire d'un certain Pierre; d'un certain Pierre et -dit-on- d'un certain loup?

Beipackzettel des H1N1 Impfst off warnt vor Gesundheitsschäden

Gesundheitliche Aufklärung, 30 September 2009
https://web.archive.org/web/20091003001100/http://www.gesundheitlicheaufklaerung.de/beipackzettel-des-h1n1-impfstoff-warnt-vor-gesundheitsschaden
https://web.archive.org/web/20091003001100/http://www.novartisvaccines.com/downloads/diseases-products/Fluvirin_PI_2009_2010.pdf

Der Beipackzettel für den H1N1 2009 Monovalent Impfstoff der von Novartis hergestellt wird ist im Internet veröffentlicht worden. Darin steht, der Impfstoff basiert auf einen Vorgänger genannt Fluvirin und kann eine ganze Reihe von erheblichen Nebenwirkungen und Gesundheitsschäden bewirken, wie das Guillain-Barre Syndrome, Vaskulitis, anaphylaktischer Schock und sogar den Tod.

Jeder der sich mit den Nebenwirkungen des Impfstoffs beschäftigt hat, weiß was dieser alles auslösen kann, aber das Besondere hier ist, nun führt der Beipackzettel der Schweinegrippeimpfung alle diese Schäden auch auf und Novartis gibt es damit zu. Auf dem Zettel steht als Datum September 2009, also ist es der neueste Stand der Information.

Influenza A (H1N1) 2009 Monovalent Vaccine. - Novartis Vaccines and Diagnostics Limited, BLA 1750, Sept 2009
https://web.archive.org/web/20091229040535/http://www.fluscam.com/Vaccine_Package_Inserts_files/Novartis_A-H1N1_2009_Monvalent_VaccinePackageInsert_BasedOn1980Approvalfor%20Fluvirin_UCM182242.pdf

Darin steht, für Kinder zwischen 4 und 8 Jahren werden zwei Injektionen a 0,5 ml mit einem Abstand von einem Monat gespritzt. Kinder ab 10 Jahren und Erwachsene bekommen nur eine Spritze a 0,5 ml.

Im Beipackzettel steht auch, die Dosis von 0,5 ml beinhaltet Thiomersal als Konservierungsmittel bestehend aus Quecksilber in einer Menge von 25 Mikrogramm. Quecksilber ist aber bekanntlich ein Nervengift und sollte deshalb vermieden werden. Wegen der kumulierenden Quecksilberbelastung von Kindern durch die routinemäßigen Kinderimpfungen wird vermutet, dass neurologische Störungen wie z. B. Autismus dadurch ausgelöst werden. (Siehe z.B. Artikel: Impfen macht krank!)

Wenn man sich die weiteren aufgeführten Nebenwirkungen ansieht, dann wird es einem ganz anders, wie zum Beispiel: Schmerzen an der Impfstelle, Ausschläge, Schwellungen, Schüttelfrost, Fieber, Müdigkeit, Asthenie, Gesichtsödeme, Störung des Immunsystem, Überempfindlichkeits-reaktionen die zu Schockzuständen und Tod führen können, Herz-Kreislaufstörungen, Vaskulitis, Ohnmachtsanfälle, Verdauungsstörungen, Durchfall, Übelkeit, Erbrechen, Bauchschmerzen, Blut- und Lymphstörungen bis hin zu Paralyse, Gehirnschäden und die Liste geht endlos weiter.

Da ist es ja viel vernünftiger die Grippe einfach durchzustehen und mit den üblichen Hausmitteln auszukurieren als sich diesen Giftcocktail reinspritzen zu lassen.

NBC NEWS

Minor side effects from early swine flu shots

NBC News, 6 October 2009, 10:46 PM +08
https://www.nbcnews.com/id/wbna33190473

Vaccine is the best tool against swine flu despite reports of a few minor side effects from the initial campaign in China, the World Health Organization said.

Four out of 39,000 people vaccinated against H1N1 in China have had side effects such as muscle cramps and headache, WHO spokesman Gregory Hartl said.

"Adverse events are fully to be expected, especially these mild types," Hartl said Monday, adding that this was particularly true in cases where very large numbers of people are being vaccinated.

The vaccination campaign will soon move to Australia, the United States and parts of Europe, he said, encouraging people – especially health care workers – to be vaccinated.

"The vaccine is the single most important tool that we have against influenza," Hartl said. "For certain groups such as health care workers, it's doubly important to get vaccinated because health care workers have the ability to protect both themselves and to protect others by getting vaccinated."

The U.S. government will be tracking possible side effects when mass flu vaccinations begin this month in hopes of quickly detecting any rare problems that are actually caused by the vaccine and not pure coincidence.

U.S. health authorities hope to give swine flu vaccinations to more than half the 300 million-plus population in just a few months.

The last mass inoculations in the United States against a different swine flu, in 1976, were marred by suggestions of a link in some cases to a rare paralyzing condition, Guillain-Barre syndrome.

Scientists never could prove that the vaccine really was linked to the syndrome, an often reversible but sometimes fatal paralysis.

Korea JoongAng Daily

Deaths in Korea from Flu Vaccination

Korea Joong Ang Daily, 15 October 2009, 19:21:25
https://web.archive.org/web/20091019040029/http://www.theflucase.com/index.php?option=com_content&view=article&id=1100:deaths-in-china-from-flu-vaccine&catid=41:highlighted-news&Itemid=105&lang=en

Five people have died after being vaccinated against seasonal influenza since the nation's health authority began providing free shots on the first day of this month.

Yesterday, an 80-year-old woman died slightly more than one hour after receiving the seasonal flu shot in Ulsan, according to the public health center in the northern part of the port city. On her way from the center in the morning, she experienced a breathing problem and fell to the ground, her daughter-in-law reported.

She was immediately moved to a nearby emergency room but died 75 minutes later. She was diabetic, according to the health center. The center is currently investigating whether the shot played a role in her death. Having secured 3.93 million doses of seasonal flu vaccine, the centers are providing free vaccines to people 65 years and older and to the needy residing in government-provided welfare facilities.

A fourth death of a flu shot recipient involved a 51-year-old man from Gyeonggi. Since he was not eligible for the free vaccination due to age, he paid for the shot. He died Oct. 9, two days after the vaccination.

The Health Ministry said an autopsy showed he died of hardening of the arteries, not from side effects from the vaccination. However, he had not been treated for heart disease before the shot.

The first three deaths occurred three days in a row beginning Oct. 5 – all involving people over 80 years old. Without elaborating further, the Health Ministry said is looking into the "possible link between the deaths and the vaccine."

This is not the first time that deaths have followed flu vaccinations. The largest tally came in 2005 at six, followed by three last year. Of the 3.93 million government-offered free vaccines doses, 3.44 million are from the Green Cross, a local pharmaceutical manufacturer.

As a follow-up measure against the recent deaths, the Korea Centers for Disease Control and Prevention, an agency under the ministry, advised that those with abnormal physical conditions should postpone the shot even if they are given notice of a free vaccination. They can reschedule later, the agency said.

The health agency noted that the seasonal flu shot "won't prevent the A(H1N1) influenza," which was originally known as the swine flu.

The agency said "healthy adults" need to give preference to senior citizens 65 and older for the seasonal flu vaccine.

Huliq News

Desiree Jennings, Cheryl Phillips

NFL Cheerleader Suffers Irreversible Dystonia after Flu Shot

Huliq News, 15 October 2009
https://web.archive.org/web/20091202080352/http://www.huliq.com/8059/87650/nfl-cheerleader-suffers-irreversible-dystonia-after-flu-shot

The debate over how safe the flu shot is appears in the news several times a week. In general, there are more risks in getting the flu itself than there are in the vaccine. However, the news that NFL cheerleader, Desiree Jennings, now suffers from a neurological condition brought on by the flu shot is causing fear in many people.

The fact that Desiree Jennings had a terrible reaction to the seasonal flu shot she received in August does not mean that everyone will have the same reaction. In reality, it may be a one in a million shot that the flu shot would cause a rare neurological disorder called dystonia. This is what Doctors at Fairfax Inova and Johns Hopkins diagnosed the NFL cheerleader with and they think it was caused by a severe reaction to the flu shot.

Dystonia is a neurological movement disorder in which sustained muscle contractions cause twisting and repetitive movements or abnormal postures. The disorder may be inherited or caused by other factors such as birth-related or other physical trauma, infection, poisoning or reaction to drugs.

Desiree Jennings, 26 was the picture of health prior to the flu shot she received on August 23. She is a Washington Redskins cheerleader and an avid runner. Ten days after receiving the flu shot, she came down with the flu. After that, her health got worse and she was hospitalized twice for seizures. Finally, she was diagnosed with dystonia and the doctors speculated that it was the flu shot that caused it.

Dystonia has been completely disabling for Desiree. She can’t walk forward, only backward. She can whisper but has difficulty speaking. Noises can cause convulsions. Her resting heart rate is 90. When she runs her blood pressure dips to 58. She gets exhausted walking a few steps but she could run for hours. Jennings now has difficulty speaking, walking, and even eating. She also experiences frequent seizures.

Desiree reported her health problems to the Food and Drug Administration (FDA) in case there was an issue with the vaccine. The FDA reported no problems with the vaccine she received and they have no other reports of adverse reactions from the lot.

NFL cheerleader Desiree Jennings, who had flu shots in 2007/2008 with no reaction, is aware that Dystonia is a rare reaction to the flu vaccine. Dystonia is an irreversible condition.

Although Desiree Jennings life is now completely changed, this reaction to the flu shot is very rare. Not getting a flu shot could have adverse affects as well, especially for those with chronic health problems.

EXPRESSEN

Svenskar drabbade av allergi efter vaccinet

Expressen, 16 Oktobre 2009
https://web.archive.org/web/20091019091129/http://www.expressen.se/halsa/1.1745698/svenskar-drabbade-av-allergi-efter-vaccinet

Tusentals svenskar har redan vaccinerats mot svininfluensa.

Nu kommer nya rapporter om biverkningar. Tre svenskar har drabbats av allergireaktioner av vaccinet.
- Det är reaktioner som tryck över bröstet, tungt att andas och rodnad på bröstet. Alla tre har tillfrisknat, säger Gunilla Sjölin Forsberg vid läkemedelsverket.

Hittills har 70 000 doser av svininfluensavaccinet Pandemrix distribuerats bara i Skåne. Ett trettiotal biverkningsrapporter har kommit till läkemedelsverket från Skåneregionen, enligt ett pressmeddelande från myndigheten. Läkemedelsverket utreder nu vilka biverkningar som har ett troligt samband med vaccinet.

Troligt samband

Hittills har myndigheten fått rapporter om tre personer som drabbats av allergiska reaktioner av vaccinet. Myndigheten har hunnit ta ställning till två av fallen, och menar att de har troligt samband med svininfluensavaccinet.

– Reaktionerna kom inom en kort tidsrymd, inom en timme från vaccineringen. Det var besvär som rodnad på bröstet, klåda, utslag och tungt att andas. Den ena personen, som fick mer uttalade besvär, fick behandling med kortison och antihistaminer. Men besvären var övergående, säger Gunilla Sjölin Forsberg, chef vid enheten för läkemedelssäkerhet vid Läkemedelsverket till Expressen.

Feber och frossa

Utöver de allergiska reaktionerna har biverkningar som smärta i armen vid stickstället, huvudvärk, feber och frossa rapporterats. Gunilla Sjölin Forsberg tycker att de rapporterade biverkningarna är lindriga och väntade och liknar de man kan få vid vaccinering mot vanlig säsongsinfluensa.

– Med tanke på att 70 000 vaccindoser distribuerats i Skåne är jag inte förvånad över antalet inrapporterade biverkningar, säger hon.
Att feber och frossa är tämligen vanligt är i linje med tidigare studier av vaccinet, som visat att mer än var tionde får övergående feberreaktioner.
För att ovanliga och allvarliga biverkningar ska kunna upptäckas måste väldigt många vaccineras. En mycket ovanlig biverkan, som alla vaccin har, är Guillain-Barrés syndrom. Det är autoimmun nervsjukdom som kännetecknas av förlamningar. I majoriteten av fallen går förlamningen tillbaka.

"Svårt fastställa samband"

Men man kan få syndromet även om man inte vaccinerar sig, exempelvis av infektioner. Antalet drabbade är mellan 0,4 och 4 på 100 000, berättar Charlotta Bergquist, vaccinexpert på Läkemedelsverket.
– Jag förväntar mig att vi kommer att få in även sådana rapporter, eftersom så många ska vaccineras. Men det blir svårt att fastställa ett samband eftersom Guillain-Barrés syndrom också kan utlösas av en infektion.

THE FLU CASE

Vaccine "side effects" reported in Sweden

The Flu Case, 17 October 2009
https://web.archive.org/web/20091021081614/http://www.theflucase.com/index.php?option=com_content&view=article&id=1125:vaccine-qside-effectsq-reported-in-sweden&catid=1:latest-news&Itemid=64&lang=en

The mass vaccination with the so called "swine flu" vaccine has started in Sweden and already some reports of side effects are becoming public. In an article in today's Expressen, it becomes clear that the strategy to deny any link between the damages made by the vaccine and the severe reactions in many victims is already in use: "Hard to establish a connection".

The cases reported by the newspaper are "allergic reactions" like pressure over the chest, difficulty breathing and redness over the chest area. The three most severe reported cases are supposed to be "well again now".

It is said that over 70 000 doses have been distributed but it is unclear how many have really received the shot so far. The thirty or so reported cases are the ones where the victim actually took the time to make the report or even had to be brought in to a hospital for treatment. The vast majority of cases though are not reported and people instead stay at home trying to cope with the "side effects".

Part from the more severe reported allergic reactions, the victims are reporting severe pain where the needle was injecting the fluid and headaches, fever and shivering.

According to the article, it is expected that more than 10% of everyone getting the shot will experience a reaction with fever involved. It is also said "To be able to discover unusual and severe side effects, very many individuals will need to be injected". The article states that the Guillain-Barrés syndrom is a disease that is known to be a side effect with every vaccine.

Since this syndome can occur in other ways, there is always the possibility to consider it not related to the vaccination to help adjust the statistics

In the Swedish Blogosphere, many report about their "side effects".

Anders Nilsson is starting to collect side effect experiences which he finds reported by bloggers in Sweden.
https://web.archive.org/web/20091019071338/http://www.andersnilsson.name/2009/10/manga-rapporterar-biverkningar-av.html

Mia says: "The night was a pain to go through, the whole arm was numb and I could not sleep" "I felt numbness and a prickly feeling all day and an undescribable pain. I have taken pain killers like candy today." "At around 6 pm, I started to feel really dizzy, my legs started shaking and I felt incredibly tired and felt so sick I just wanted to die."
https://web.archive.org/web/20111120210750/http://frukenob.blogspot.com/2009/10/svininflensan.html

A mother of three writes: "Woke up this morning with severe pain in my arm, like pain after a workout, felt headache and nausea", "at work I could no longer bear the headache, it pounded like h*ll and I felt a fever coming …. at lunchtime I could no longer take it so I reported sick and will do so also for tomorrow. On the way home I puked as crazy."

Manda writes: Vaccines suck. My arm hurts like h*ll, I have a fever and coldsweats, feeling sick and puke and on top of that I almost faint every now and then."
https://web.archive.org/web/20091022183537/http://mandascrazythoughts.bloggproffs.se/2009/10/14/uff/

Jennely writes: "Stayed home from work today since I did not get many minutes of sleep last night, could hardly stand up this morning because my head felt like it was spinning and I started to feel very nauseous. All due to the pain in my arm after the vaccination, having so much pain that it is unbelievable.", "Never thought one could be in such pain from a small little vaccination, have had vaccinations before which I never felt."
https://web.archive.org/web/20091022133352/http://blogg.vk.se/nenny/2009/10/15/aj-aj-141294

If you have received the "swine flu" shot, it is important that you report any side effects - no matter if they show up directly after the vaccination or weeks after. The long term effects will not be known until they are properly researched.

Woman Disabled by this Years Flu Shot
10 days after vaccination

Russia Today (RT), 18 October 2009
https://www.youtube.com/watch?v=1FrbhM05Wi4

A shocking side effect to a routine vaccination this started a flu shot you heard her right a regular flu shot gone horribly wrong tonight the warning this woman wants everyone to hear good evening everyone I'm Brian Bolter and I'm sea yansy a few weeks ago Desiree Jennings was training for a half marathon tonight she's struggling to walk talk even eat left disabled by a very rare reaction to a seasonal flu shot plenty of coffee has more on this serious side effect the vast majority of doctors say flu shots are safe in this case the FDA says they found nothing wrong with this particular batch but sometimes there are complications and that's apparently what happened to Desiree Jennings and now her life will never be the same here 26-year-old Desiree Jennings is the picture of health she's a Redskins cheerleader Ambassador and an avid Runner her life changed Forever on August the 23rd when she says she got a seasonal flu shot ... 190-tal biverkningar av vaccinet

DN.se, 21 October 2009, 22:01
https://web.archive.org/web/20091025161907/http://www.dn.se/nyheter/vetenskap/190-tal-biverkningar-av-vaccinet-1.979474

Från och med torsdagen lägger Läkemedelsverket varje vecka ut alla rapporterade biverkningar av vaccinet mot svin-influensan på sin hemsida. Hittills har ett 190-tal biverkningar anmälts till myndigheten.

Mer än en halv miljon doser av influensavaccinet Pandemrix har skickats till landstingen. Flera tusen svenskar har fått vaccinet och nu kommer anmälningar om biverkningar till Läkemedelsverket.

Hittills har myndigheten fått in mer än 190 rapporter från både sjukvården och privatpersoner. Allra vanligast är smärta i armen. Sen kommer milda influensasymtom som feber, muskelvärk, magont, huvudvärk, yrsel och trötthet.

– Det är vanliga biverkningar efter influensavaccin och det är vad vi hade väntat oss, säger Gunilla Sjölin Forsberg som är chef för läkemedelssäkerhet på Läkemedelsverket.

Enligt vaccintillverkaren Glaxo-smithkline får ungefär en av tio vaccinerade besvär, vilket är något fler än för vanligt säsongsinfluensavaccin. Det beror på ett ämne i vaccinet som triggar i gång immunförsvaret.

Läkemedelsverket utreder också ett dödsfall som har skett efter en vaccination.

– Det är en hjärtsjuk person i Västernorrland som har fått en misstänkt hjärtinfarkt. Hittills har vi inte hittat något stöd för att dödsfallet har samband med vaccinsprutan, säger Gunilla Sjölin Forsberg.

THE FLU CASE

Johan Niklasson

Nurses got sick from the "swine flu" vaccine in Sweden
update - 1 suspected death

The Flu Case, 21 October 2009, 16:45
https://web.archive.org/web/20091024040135/http://www.theflucase.com/index.php?option=com_content&view=article&id=1268:they-got-sick-from-the-vaccine-in-sweden&catid=1:latest-news&Itemid=64&lang=en

Yesterday 30 people had been reporting to the authorities in Sweden that they experienced such severe side effects that they felt the need to contact a hospital. Today the number is 140. The swedish newspaper *Expressen* is the only one in Sweden reporting on these cases and as usual this is most likely only the tip of a rather large iceberg.

Update: According to ***Dagens Nyheter***, the number of reported side effects are now a few hours later 190.
See above: Anna Bratt. **190-tal biverkningar av vaccinet.** – DN.se, 21 October 2009]
https://web.archive.org/web/20091024055129/http://www.dn.se/nyheter/vetenskap/190-tal-biverkningar-av-vaccinet-1.979474

1 person dies after the injection but "no direct relation with the injection has been established". The biggest medical scandal in the history of Sweden has just started.

Even so, Annika Linde, director of The Swedish Institute for Infectious Disease Control (SMI) manages to spin this into something positive by stating "*The vaccine has more side effects than the normal flu vaccine. It is a sign that proves that it gives an effective protection.*"

Thousands of Swedes have been vaccinated so far and the reports of side effects are "flooding in" to The Swedish Institute for Infectious Disease Control (SMI). Annika Linde: "It is obviously so that the vaccine against the swine flu results in more side effects than the normal flu vaccines. That is because the swine flu vaccine contains adjuvants, shark liver oil, which triggers the immune defense to respond. That also results in that the protection against the virus becomes better."

Several severe cases of allergic reactions are reported to the unit for medicinal safety. "So far the reported side effects are not unexpected", says Gunilla Sjölin Forsberg. This unit has now asked some of the many units that vaccinate to report side effects to better get a grip on the situation. This statement alone is shocking since according to normal practice, all side effects should automatically be reported - right?

A nurse who took the shot on wednesday last week is still feeling sick. She got high fever and shivers from the swine flu shot. "*I was shaking in my whole body. It was so sever that I could not even hold a glass of water in my hand*", **Lotta Lindström** says. "*I am now thinking about what it is I have been injected with. I really was affected. It feels really unpleasant*."
See: Anna Bäsén, Nathalie Joo. **De blev sjuka av vaccinet**. - Expressen.se, 24 oktober 2009
https://web.archive.org/web/20091024055220/http://www.expressen.se/halsa/1.1750592/de-blev-sjuka-av-vaccinet

Maria Strindlund is not so sure she made the right choice to tae the shot. She also got a severe fever and shivering reaction. "*Since I work as a nurse, I decided it was the best thing to do*.", she says. At first she felt nothing from the vaccinaton, but a few hours later the side effects kicked in. "*I got a extreme pain in my arm. I could no longer lift it*." The came the fever and the shivering. "*I was lying in bed shivering and was feeling very cold and stood in a hot shower to get warm*." She says many colleguse who also took the vaccine have had similar reactons. She has been taking many vaccines in the past without any reactions whatsoever.

See: Nathalie Joo. **Maria, 27: "Fick fruktansvärt ont"**. – Expressen.se, 24 oktober 2009
https://web.archive.org/web/20091024075950/http://www.expressen.se/halsa/1.1750595/maria-27-fick-fruktansvart-ont

Rebecka Andersson was the first person to get the shot in Sweden. She became feverish and felt sick to her stomach from the shot. "*I lost all energy*", she says. "*I am normally never sick so I understood it must be the vaccine*." Her class mates was vaccinated at the same time and she states that five out of nineteen also got sick from the swine flu vaccine.

See: Nathalie Joo. **Rebecka, 32: "Jag blev orkeslös"**. – Expressen.se, 24 oktober 2009
https://web.archive.org/web/20091024075956/http://www.expressen.se/halsa/1.1750598/rebecka-32-jag-blev-orkeslos

Lotta Lindström, a nurse, states that she got the shot a week ago and still is not well. "*It feels very worrying*", she says. "*I did not sleep anything the night after the shot since the pain in my arm was so severe*." The day after, at work, the fever came. She later had headaches. She still today, a week after the shot feels sick.

See: Nathalie Joo. **Lotta, 49: "Jag sov inte något på natten"**. – Expressen.se, 22 oktober 2009
https://web.archive.org/web/20091022155329/http://www.expressen.se/halsa/1.1750596/lotta-49-jag-sov-inte-nagot-pa-natten

Another nurse, **Jennely**, could hardly walk five meters after she got sick from the "*swine flu" vaccination. She was completely healthy when she got the shot but the day after she had 39 degrees centigrade fever* (102.2 F). "*I could hardly walk the five meters I had to the bathroom*", she says. The fever lasted for three days. sevreal of her colugueges at work had similar experiences. "*I know of at least ten that got fever , we are about 80 people at my workplace*."

See: Nathalie Joo. **Jennely, 26: "Orkade knappt gå fem meter".** – Expressen.se, 22 oktober 2009.
https://web.archive.org/web/20091022194101/http://www.expressen.se/halsa/1.1750600/jennely-26-orkade-knappt-ga-fem-meter

EXPRESSEN

Anna Lindström, Behrang Behdjou

Två personer avled kort efter vaccinering

Expressen, 22 Oktobre 2009
https://web.archive.org/web/20091025035951/http://www.expressen.se/Nyheter/1.1752585/tva-personer-avled-kort-efter-vaccinering

Två svårt sjuka människor har avlidit efter att ha fått vaccin mot svininfluensan.

Nu utreds dödsfallen av Läkemedelsverket.
- Vi vet ännu inte om det finns något samband, säger Lennart Waldenlind som är docent vid Läkemedelsverket.

En av den avlidna, en man som var i 55-årsåldern vaccinerades på morgonen fredagen 16 oktober. Tolv timmar senare avled han.
- Han var svårt hjärtsjuk och hade svikt även i andra vitala organ, uppger Hans Boman, smittskyddsläkare i Västernorrland, för Expressen.se.

Bör man vaccinera sig då?
- Ja, för då tillhör man en riskgrupp och det var därför han gick och vaccinerade sig.

Boman säger att han inte tror att dödsfallet har samband med svininfluensan.
- Min bedömning är att det har ett slumpmässigt samband till vaccinationen, men vi måste avvakta utredningen.

"Bedöms på nationell nivå"

Mannen har obducerats och primärvården har beställt in hans journaler och biverkningsrapporten.

Är det möjligt att ni vidtar åtgärder om dödsfallet har samband med vaccinationen?
- Det får bli en bedömning på nationell nivå hur man ska ställa sig, men det är ett enda dödsfall av hundratusentals vaccinationer. Det är knappast troligt att det har något samband.

Lennart Waldenlind som är docent vid Läkemedelsverket säger att det på torsdagseftermiddagen rapporterades in ytterligare ett misstänkt dödsfall.
- En svårt muskelsjuk kvinna i 60-årsåldern avled plötsligt i sitt hem två dygn efter att ha fått vaccin mot svininfluensa. Vi skall nu utreda de båda dödsfallen för att se om det finns något samband med vaccinet, säger han och tillägger:
- Det skulle kunna vara så att febern som kan uppstå efter vaccinet blir en för stor påfrestning för redan svårt sjuka då detta vaccin är starkare än vanligt influensavaccin. Men det är så klart omöjligt att vara Gud Fader själv och ha alla svar från början. I bland kan det vara så att man förstår ett samband först efter ett tag.

THE FLU CASE

Johan Niklasson

First deaths in Sweden from "swine flu" vaccine

The Flu Case, 22 October 2009
https://web.archive.org/web/20091026142132/http://www.theflucase.com/index.php?option=com_content&view=article&id=1281:first-deaths-in-sweden-from-qswine-fluq-vaccine&catid=1:latest-news&Itemid=64&lang=en

We have already reported about the over 200 official cases of "side effects" from the "swine flu" mass vaccination that is taking place in Sweden. => https://web.archive.org/web/20091026142132/http://www.theflucase.com/index.php?option=com_content&view=article&id=1268%3Athey-got-sick-from-the-vaccine-in-sweden&catid=1%3Alatest-news&Itemid=64&lang=de

So far, only the so called "risk groups" are targeted, people who are sick, work in hospitals or are pregnant(!). Historically, the reports of side effects are normally just the tip of an iceberg and if the past is any guide, no more than a maximum of 10% of all cases are reported. Officials even make statements to the effect that it is unusual to report side effects. It has been said from the authorities in Sweden that "we now will begin to ask people to report serious side effects, those who are not already known." With such strategy, very few cases will even be considered to be reported and to reveal that it is normal to not consider the already known damages is shocking.

Today, Aftonbladet reveals that two Swedes have died from the Pandremix "swine flu" shot. => http://www.aftonbladet.se/nyheter/article6001249.ab

Media in Sweden have consistently been promoting the mass vaccination and have systematically blocked any debate or critical voices from being published. Vaccinations have just begun but already they have killed more than the so called "swine flu" has done in Sweden. The propaganda have constantly repeated that "we need to get vaccinated to avoid to infect others and to save society from the economic loss if many are sick at the same time. The flu will kill many more than the vaccine ever will." Another blatant lie to add to the numerous others.

In what seems to be the first signs of taking a different stance towards the vaccines, Aftonbladet today reveals that two elderly citizens who took the vaccine died shortly after. They were both already sick or had serious health problems. One of them was an elderly man who died of what looks like a heart attack. The other one was a woman aged 65 who was found dead in her home two days after she got vaccinated. It is said she suffered from a "muscle condition".

Even though it is obvious that the vaccination is causing severe side effects, including death, health officials deny the connection. Lennart Waldelind who works for The Medical Products Agency says "It is very hard to judge. It is a matter of personal preference how one declares this."

In Expressen he says about damages from vaccines: "Sometimes one can only realize a connection after a while." => https://web.archive.org/web/20091025035951/http://www.expressen.se/Nyheter/1.1752585/tva-personer-avled-kort-efter-vaccinering

It can not have come as a surprise to the Swedish authorities that this vaccination would lead to enormous problems, there have been more than enough warnings sent in from hundreds if not thousands of concerned individuals.

Lennart Waldelind explains that warnings directed to elderly people regarding the "swine flu" vaccine are now being formulated and prepared by The Medical Products Agency. It will be very interesting to see who will take the responsibility for this large scale deadly testing of a new vaccine on a defenseless and misinformed public.

The headline in Aftonbladet reads: "The flu vaccine may be too strong".

The biggest medical scandal in the history of Sweden has just started.

AFTONBLADET

Jessica Balksjö

"Influensavaccinet kan vara för starkt"
Elderly seriously ill people may be advised against vaccination

Aftonbladet, 22 October 2009
http://www.aftonbladet.se/nyheter/article6001249.ab

Äldre allvarligt sjuka kan avrådas från vaccination

Två allvarligt sjuka personer har hittills dött efter att de fått vaccinet mot svininfluensan.

Läkemedelsverket utreder nu om det kan krävas nya rekommendationer som avråder äldre och sjuka att vaccinera sig.

– I de kliniska testerna som görs inför en vaccination så finns det få av de här ovanliga patienterna representerade, säger Lennart Waldenlind, läkare på Läkemedelsverket.

Två allvarligt sjuka personer har hittills dött efter att de fått influensavaccinet. En av dem är en man i Västernorrland som fick en hjärtattack. Läkemedelsverket kan ännu inte säga om hans dödsfall är en reaktion på vaccinet. En obduktion ska göras för att reda ut orsaken till hjärtattacken.

– Det är mycket svårt att bedöma. Någon kan göra bedömningen att det inte finns ett samband. Det är en personlig sak hur man bedömer, säger Lennart Waldenlind, läkare på Läkemedelsverket.

En allvarligt lungsjuk kvinna i 65-årsåldern från Stockholmsområdet hittades död två dagar efter att hon hade fått vaccinationen. Det fallet kommer också att utredas av Läkemedelsverket.

Borde allvarligt sjuka personer avstå från att vaccinera sig?

– Det är en adekvat fråga och något vi jobbar på att utreda. Vid de kliniska studier som görs inför vaccinationer så finns det ofta inte så många av de här ovanliga patienterna representerade. Erfarenheten av hur de reagerar kommer senare. Vi jobbar just nu med varningar om försiktighet, säger Lennart Waldenlind.

Vaccinet mot svininfluensan skiljer sig från vanligt influensavaccin genom att delen så kallad adjuvans är högre. Det är den komponenten som sätter igång immunförsvaret hos personen som får det.

– Det här kan förklara att man kan se lite kraftigare reaktioner än på ett vanligt vaccin. Har man väldigt många riskfaktorer som gör att man kan må dåligt av febern som uppkommer så kan det kanske vara så att man ska avstå. Det verkar ju dessutom som att äldre sällan insjuknar i influensan. Det här är något vi utreder och det finns ingen tidsplan över när vi vet svaret, säger Lennart Waldenlind.

ALEX JONES' INFOWARS.COM BECAUSE THERE IS A WAR ON FOR YOUR MIND

Deaths from Swine Flu Vaccine reported in Europe
Vaccine manufacturer attributes high rate of side effects to novel adjuvants

Infowars, 23 October 2009

https://web.archive.org/web/20091026154337/http://www.infowars.net/articles/October2009/231009Vaccinations.htm

As European governments forge ahead with mass swine flu vaccination programs, reports out of Hungary and Sweden suggest that some people have died shortly after taking the H1N1 vaccine.

The Budapest Times is reporting that a 64-year-old woman has died just two days after receiving the H1N1 shot.

An autopsy has been scheduled to determine if there is a link between the vaccine and the death of the patient, who suffered from chronic, but mild, heart disease, according to the article.

So far just 4 people have died from swine flu in Hungary.

The country's H1N1 vaccine is being supplied by local vaccine manufacturer Omninvest. The government there has ordered six million doses cover about 60% of Hungary's population of 10 million.

Omnivest's vaccines are egg grown and adjuvanted with aluminum phosphate. The company says that only one dose of their H1N1 vaccine is required. Though they have conducted limited trials with the H1N1 virus, their vaccine, is based on tests with the avian flu strain.

According to the Budapest Times report, Omnivest has threatened to sue over allegations that its swine flu vaccine may be dangerous. However, a leading advisor to the Health Ministry in Hungary, last week suggested that the vaccine is not suitable for small children and pregnant women, in spite of the fact that the shot is being offered to free of charge to those "at risk" groups.

Reports are also emerging out of Sweden that suggest more deaths have occurred.

According to the Swedish newspaper Aftonbladet, medical experts have said that a man in his fifties died of a suspected heart attack 12 hours after receiving the Pandemrix shot, which is manufactured by GlaxoSmithKline.

The newspaper also reported that a 65-year-old women died two days after receiving the jab, she is reported to have suffered from a "muscle condition".

Here is a rough translation of the article via Google translator: [an original text is above]

Flu vaccine may be too strong

Mature, seriously ill can be dissuaded from vaccination

Two seriously ill persons have so far died after receiving the vaccine against swine flu.

MPA is now investigating whether it may require new recommendations advise against the elderly and sick to immunize itself.

Two seriously ill persons have so far died after receiving flu vaccine. One of them is a man of Västernorrland who had a heart attack. MPA can not say if his death is a reaction to the vaccine. An autopsy will be done to clarify the cause of heart attack.

"It is very difficult to assess. Someone may consider that there is a connection. It's a personal thing how to assess," says Lennart Walden Lind, doctors at the MPA.

A severe consumptive woman in the age of 65 from the Stockholm area, was found dead two days after she had received the vaccination. The case will be investigated by the MPA.

Should seriously ill people not to vaccinate themselves?

"There is a proper question, and we're working on something to investigate. In the clinical studies performed before vaccination, there is often not so many of these rare patients are represented. The experience of how they react will come later. We are working right now with warnings of caution," said Lennart Walden Lind.

The vaccine against swine flu differs from ordinary flu by most so-called adjuvants are higher. It is the component which triggers the immune system of the person receiving it.

"This can explain that one can see a bit stronger reactions than on a conventional vaccine. If you have many risk factors that allows one to feel bad by fever arising as it may be that you should abstain. It seems besides, as the elderly often fall ill in flu. This is something we are investigating and there is no timetable on when we know the answer," says Lennart Walden Lind.

Other reports out of Sweden suggest that 190 people, including many nurses have reported suffering side effects from the vaccine to the medical authority (MPA).

"So far, the authority has received more than 190 reports from both health care and private individuals. By far the most common are pain in the arm. Then mild flu symptoms like fever, muscle pain, stomach pain, headaches, dizziness and fatigue." reports Swedish news website DN.se.

The report goes on to state that GlaxoSmithKline is attributing a higher than normal rate of side effects to the adjuvants in the vaccine:

"According to vaccine manufacturer GlaxoSmithKline may be about one in ten vaccinated trouble, which is slightly more than the usual seasonal influenza vaccine. This is because a substance in the vaccine that triggers immune response in time." the translation reads.

GlaxoSmithKline’s Pandemrix vaccine contains the adjuvant squalene.

Vaccinations began throughout Europe a little over a week ago. Sweden was one of the first countries to begin vaccination on October 12.

According to the Stockholm-based European Centre for Disease Prevention and Control, there have been a total of 230 deaths linked to H1N1 in Europe since April, with around 50% of those occurring in the UK.

Grippe: Vaccin mortel Retour aux dépêches
Quatre décès après une vaccination contre la grippe ont provoqué la panique à Israël

Synt-L'Economiste/AFP, 23 Octobre 2009, 14h47
(https://www.leconomiste.com/ xxx)

Agées de 53 à 75, les victimes ont toutes été vaccinées au même endroit, au cours des huit derniers jours. Le ministère de la Santé israélien a annoncé dimanche dernier les 4 décès, ordonnant la suspension de toutes les vaccinations contre la grippe.

L'affaire a éclaté lorsqu'une infirmière de Kiryat Gat (sud d'Israël) a informé les autorités que 3 de ses patients étaient morts après avoir reçu le vaccin anti-grippe mis au point par le groupe français Sanofi-Aventis. Une autre victime a été déplorée plus tard.

Le groupe pharmaceutique a annoncé lundi 23 octobre avoir mobilisé ses spécialistes en pharmacovigilance pour examiner les circonstances des décès. A noter que Sanofi-Aventis Maroc n'était pas joignable en cette période de fête.

Quant aux responsables à l'Institut Pasteur, ils ne sont pas "au courant de cette affaire". Contacté par L'Economiste, le Pr Abdelaziz Agoumi, directeur des médicaments et de la pharmacie au ministère de la santé a indiqué que la campagne anti-grippe se déroulait "sans incidents" chez nous.

Israel Suspended Swine Flu Jabs after Four Deaths

The Flu Case, 28 November 2009, 10:23
https://web.archive.org/web/20100102051316/http://theflucase.com/index.php?option=com_content&view=article&id=2099%3Aisrael-suspended-swine-flu-vaccination-campaign-on-october-22nd-following-four-deaths&catid=41%3Ahighlighted-news&Itemid=105&lang=en

Israel suspended its swine flu vaccination campaign on October 22nd following the deaths of four people, according to a report from Synt-L'Economiste/AFP.

Four people aged between 53 and 75 years old died during the last eight days after being given a swine flu jab by Sanofi Aventis at the same place.

A nurse at Kiryat Gat in southern Israel informed the authorities that 3 patients had died after receiving the swine flu jab. The fourth person died later.

Sanofi Aventis has said it is investigating the deaths.

Two people drop dead in Sweden after Swine Flu Shot
Tip of the Iceberg

The Flu Case, 23 October 2009
https://web.archive.org/web/20091026145017/http://www.theflucase.com/index.php?option=com_content&view=article&id=1311:two-people-drop-dead-in-sweden-after-swine-flu-shot-tip-of-the-iceberg&catid=41:highlighted-news&Itemid=105&lang=en

Two people have dropped dead in Sweden after taking the "swine flu" vaccine, the Swedish newspaper Aftonbladet reported yesterday.

Gunillla Sjolin-Forsberg from the Sweden's Medical Product's Agency (Läkemedelsverket) said that a man in his fifties died 12 hours after receiving the Pandemrix "swine flu" shot, which is made by GlaxoSmithKline.

A 65-year-old women died two days after receiving the "swine flu" jab, according to Aftonbladet.

The deaths were reported within days of the launch of the country's mass "swine flu" vaccination programme.

GlaxoSmithKline's Pandemrix vaccine, which contains the adjuvant squalene, is classified as bioweapon by EU and US regulators according to a biopharma databas.

According to the Swedish newspaper Expressen, 190 nurses reported suffering serious side effects after receiving the "swine flu" shot. Side effects reported include extreme pain in the arm at the point of injection, an inability to sleep after injection; profuse and continuous nausea and vomiting; falling blood pressure, severe headaches, fainting, fevers, muscle aches.

A Swedish nurse who took the shot Wednesday a week ago told Expressen:. "My whole body was shaking. It was so bad I couldn't even hold a glass of water in my hand."

Another nurse, Jennaly, could hardly walk five meters after being sick following the "swine flu" vaccination. She was completely health before taking the shot but the following day she had a fever of 39 degrees.

"I could hardly go five meters to the bathroom," she said.

The fever lasted three days. Many of her colleagues who took the jab suffered from similar side effects. "I know of at least ten who got fever. We are 80 people where I work."

Rebecka Andersson, the first person in Sweden to be vaccinated, said she got a fever and felt sick. "I lost all my strength," she said. "I am never sick so it was the vaccine in my case. Her classmates were vaccinated at the same time. Five of the 19 became sick through the "swine flu" jab.

Sjolin-Forsberg said in a phone interview with theflucase today, Friday, that the agency had officially received only100 reports from doctors and another 100 from patients so far about side effects, but she admitted that the agency's data on side effects were not up to date and collected on a weekly basis and that the agency relied on "spontaneous" reports.

Six of these reports were classified by the agency as serious, she said. Among this group were people who were hospitalised as a result of allergic reactions to the jab.

She indicated that the "swine flu" jab was not responsible for the death of the man in his fifties but that heart disease was.

However, the jab was targetted at sick people on the grounds that it is supposed to help people not kill them.

There is no clinical data on the impact of the jab on pregnant women and children even though these are also target groups.

It is not clear how many people in Sweden have received the swine flu jab so far.

Sjolin-Forsberg said that 500,000 doses of the vaccine had been delivered, but that the agency had no data on how many "swine flu" shots had actually been administered.

The Swedish infectious disease control agency, SMI, responsible for collecting the data of vaccinations said that their system for tracking vaccinations, Svelak, covered only some hospitals, and there was, therefore, no system in place for collecting comprehensive data.

The SMI press spokesperson Aase Sten could not be reached by phone at the time of writing this report. Pandemrix, like all other swine flu jabs, has been given approval by the EMEA under special emergency pandemic regulations that do not require the drug to be tested for "safety and efficacy" before it is administered as long as studies are carried out after it is administered.

The absense of data concerning how many "swine flu" shots have been administered means that the frequency of side effects in relation to the number of shots administered cannot be accurately calculated.

Accurate data on the frequency and severity of the side effects are, however, key to determine whether the vaccine is safe and efficacious and also as to whether to continue with the programme.

The Swedisch governmnent is required by law to have in place a study to monitor the side effects of the "swine flu jab".

However, there is no formal mechansm or requirement for reporting reactions to the "swine flu" jab in Sweden even though the vaccine campaign is now underway,

Sjolin-Forsberg confirmed the agency has been relying on "spontaneous" reports from doctors and patients. She said the agency was not currently conducting any study into side effects, but that a study is being planned. She was not able to give specifics about this study, and advised www.theflucase.com to contact the pharamceutical companies to find out more information about studies underway to monitor the side effects of the vaccines.

The newspaper Aftonbladet reported that the authorities are only now going to ask some vaccine centers to report "side effects."

The failure of the Swedish government to put in place adequate monitoring systems will fuel fears that the number of people suffering death and damage as a result of the swine flu shot in Sweden reported by the medical product's agency is only the tip of the iceberg.

BILD.de-Moderatorin Hadnet Tesfai (30) noch immer müde

Nu är den stora influensavågen här

Aftonbladet, 23 Oktober 2009
http://www.aftonbladet.se/nyheter/article6007590.ab

Rekordmånga bekräftade fall förra veckan

Nu har den stora vågen av svininfluensa slagit till.Rekordmånga bekräftade fall av svininfluensa rapporterades i förra veckan– och allt talar för att det blir värre.

Idag meddelades också ett tredje dödsfall som kan ha koppling till vaccinet.

I förra veckan nåddes en toppnotering på antalet bekräftade fall av svininfluensa. 198 nya fall rapporterades. Veckan dessförinnan var motsvarande siffra 93. Bara under vecka 35 har siffrorna varit i närheten, då var det 167. Troligen är detta den stora vågen av svininfluensan.

– Allt talar för att det här är den stora vågen, det andra var bara en sockertopp, säger Annika Linde, smittskyddsläkare på Smittskyddsinstitutet.

Över strax innan jul

Den stora vågen brukar öka under tre veckor. När den har nått toppen har man tre toppveckor.

– Om det här är början på den stora vågen borde den vara över strax före jul, säger hon.

Det kan bli ytterligare en topp i april, beroende på hur vaccineringen går.

Varför slår svininfluensan till med full kraft just nu?

– Det är dags. Vi har hela tiden räknat med det. Vädret är det som påverkar mest. När det är kallt innehåller luften mindre fukt. Då börjar viruset spridas flygande istället för som tidigare via droppar.

– Alla trodde att faran var över efter första puckeln men det är den inte, säger Annika Linde.

Sprids värst i skolorna

Det är framför allt i skolorna som smittspridningen har tagit fart.

– Det börjar i skolorna sen kommer barnen hem och smittar sina föräldrar och småsyskon. Det här är klassisk influensaspridning.

Varför är det värre i skolan än på arbetsplatsen?

– På skolorna är det intimt på ett sätt som det inte är på arbetsplatserna, och vuxna är ofta mindre känsliga för influensor. Men man är lika intim i hemmen som i skolorna och det är där de vuxna kommer att smittas.

Novemberlovet som är för skolbarnen i nästa vecka kan avstanna spridningen.

– Lovet kommer minska spridningen eftersom skolorna stänger. Men det är inte lika effektivt som ett sommarlov för många barn kommer ändå vara på fritids.

Tre misstänkta dödsfall

Nu utreds ett tredje dödsfall som kan ha koppling till vaccinet mot svininfluensan. En 74-årig kvinna avled i Sollefteå fyra dagar efter det att hon hade vaccinerat sig. Kvinnan tillhörde riskgrupperna, hon led av bland annat hjärtsjukdom och KOL.

Sedan tidigare utreds två dödsfall med misstänkta kopplingar till vaccinet.

– Det är viktigt att säga att det är patienter med komplicerande sjukdomar. Vi vet inte ännu om dödsfallen har något samband med vaccineringen, säger Gunilla Sjölin Forslund på Läkemedelsverket till TT

=>

[**Third "Swine Flu" vaccine death reported in sweden**. – The Flu Case, 23 October 2009]

In an article in the Swedish Aftonbladet, it is stated that a third death is investigated as likely to be due to vaccination with the "swine flu" vaccine. The woman was 74 years old and died 4 days after she got the flu shot. She had a heart disease and lung problems and was therefor part of the so called risk group which is the first to get the "swine flu" shot in Sweden.

THE FLU CASE

Fourth "Swine Flu" vaccine death reported in Sweden

The Flu Case, 24 October 2009, 10:28

https://web.archive.org/web/20091028005358/http://www.theflucase.com/index.php?option=com_content&view=article&id=1350:fourth-vaccine-death-reported-in-sweden&catid=41:highlighted-news&Itemid=105&lang=en

Dagens Nyheter reports that a fourth case of death caused by the "swine flu" shot has occurred in Sweden. A very old woman, 90 years old, died a few days (yesterday) after she received the "swine flu" Pandemrix shot. This is the fourth death suspected to be a direct result, or so called "severe side effect" of the new untested and adjuvant spiced injection. The levels of squalene in the Swedish shots are many thousand times higher than in those vaccines that caused the Gulf War Syndrome which so far has killed or severely damaged over 30.000 American soldiers.

Sweden had a contract with GlaxoSmithKline which forced Sweden to purchase a certain amount of vaccines (18 million doses ordered) in the event of a Pandemic level 6 declaration from WHO.

The vaccine manufacturer and other manufacturers are advisors to the WHO regarding pandemic declarations. The Swedish authorities have recently had to admit to parts of the still secret contract with the vaccine manufacturer - that they indeed were bound to order the vaccine.

The Pandemic level 6 definition was changed earlier this year by WHO so that the lower level of severity would include every "normal influenza" for the last 30 years. Earlier a pandemic also had to cause many deaths which the "swine flu" so far has not. Now, any flu would cause a pandemic level 6 declaration.

Swedish authorities keep stating that the people now getting the vaccine are often already sick, they are part of a so called "risk group" with weakened immune systems. Strangely, perfectly healthy pregnant women are part of this group. No abortions due to the vaccine are reported so far but are expected. Authorities makes statements to the effect that the recent deaths have nothing to do with the vaccination. "These individuals had pre-existing health problems, it is just coincidence they died now." In swedish media, and also in many other countries, any case where someone have had the "swine flu" and died, has been declared as an direct cause of the "Swine flu", no matter if the real cause of death was pneumonia or bacterial infection or a pre-existing condition. This comment from one of our readers sums it up well: "*Funny how when someone dies of swineflu with a pre-existing condition they died from swineflu - no question. And if someone dies from the vaccine with a pre-existing condition they died from the pre-existing condition - no question*." There are fears that any investigations into these deaths will be resulting in reports that are lying about the cause of death so to not disturb the ongoing mass vaccination of the Swedish population, a campaign which so far still is volontary for most people. Sweden can force vaccinate everyone in the country if it is deemed necessary by the authorities. The problem is that everyone in a leading position in Sweden are believers in vaccines and their alleged effect and many of them also have ties to the pharma industry. The vaccine maffia rules the nations health care policies.

Reports of new outbreaks of "swine flu" litters the news papers in Sweden, as if they have to beat the drum to scare more into taking the vaccine now when doubts about the safety of the untested and poisinous drug Pandemrix is spreading. The fact that tests are very unreliable (9 in 10 show the false result) does not appear anywhere in these articles and that other forms of flu now spread as usual is also not mentioned.

The question of responsibility when it comes to severe side effects including death is still unclear. Swedish authorities have earlier officially stated that there is no immunity for the vaccine manufacturers but after receiving a direct question from us, they removed that information from their web site and have not replied to our inquiry further. The fact that the European parliment have passed laws which gives the vaccine manufacturers complete immunity has not been reported in Swedish media. Who then will have to take responsibility seem to be completely unclear in Sweden.

REUTERS

WHO probes study seasonal shot may raise H1N1 risk

Reuters, 24/25 September 2009, 12:28 am
https://www.reuters.com/article/idUSWEA2303/

GENEVA, Sept 24 (Reuters) - The World Health Organisation said on Thursday it was looking into an unpublished Canadian study indicating that a seasonal flu shot could increase the risk of catching the H1N1 virus.

Marie-Paule Kieny, director of the WHO's initiative for vaccine research, said no other researchers had presented similar findings and it could be a "study bias", although the Canadian investigators were well known and capable.

"The reason why this may be different in Canada and in this particular study than in other places of the world is not yet identified. It may be a study bias, it may be that something is real," Kieny told a teleconference from the WHO headquarters.

She said all drug manufacturers who produced seasonal influenza shots will be able to make H1N1 vaccine, for a total annual output of 3 billion doses. Health workers, who make up 2 percent of the world's population, should be a priority. (Reporting by Stephanie Nebehay; editing by Andrew Dobbie)

INFORMATION LIBERATION

Steve Watson

Deaths From Swine Flu Vaccine Reported in Europe
Vaccine manufacturer attributes high rate of side effects to novel adjuvants

Information Liberation, 25 October 2009
https://www.informationliberation.com/?id=27733

As European governments forge ahead with mass swine flu vaccination programs, reports out of Hungary and Sweden suggest that some people have died shortly after taking the H1N1 vaccine.

The **Budapest Times** is reporting that a 64-year-old woman has died just two days after receiving the H1N1 shot.
=> https://web.archive.org/web/20091023073237/http://www.budapesttimes.hu/content/view/13267/219/

An autopsy has been scheduled to determine if there is a link between the vaccine and the death of the patient, who suffered from chronic, but mild, heart disease, according to the article. So far just 4 people have died from swine flu in Hungary. The country's H1N1 vaccine is being supplied by local vaccine manufacturer **Omninvest**. The government there has ordered six million doses cover about 60% of Hungary's population of 10 million.

Omnivest's vaccines are egg grown and adjuvanted with aluminum phosphate. The company says that only one dose of their H1N1 vaccine is required. Though they have conducted limited trials with the H1N1 virus, their vaccine, is based on tests with the avian flu strain.

According to the Budapest Times report, Omnivest has threatened to sue over allegations that its swine flu vaccine may be dangerous. However, a leading advisor to the Health Ministry in Hungary, last week suggested that the vaccine is not suitable for small children and pregnant women, in spite of the fact that the shot is being offered to free of charge to those "at risk" groups.
Reports are also emerging out of Sweden that suggest more deaths have occurred.

According to the **Swedish newspaper Aftonbladet**, medical experts have said that a man in his fifties died of a suspected heart attack 12 hours after receiving the Pandemrix shot, which is manufactured by GlaxoSmithKline.
=> https://www.aftonbladet.se/nyheter/a/4dEw7V/influensavaccinet-kan-vara-for-starkt

The newspaper also reported that a 65-year-old women died two days after receiving the jab, she is reported to have suffered from a "muscle condition".

Here is a rough translation of the article via Google translator:

Flu vaccine may be too strong

Mature, seriously ill can be dissuaded from vaccination. Two seriously ill persons have so far died after receiving the vaccine against swine flu. MPA is now investigating whether it may require new recommendations advise against the elderly and sick to immunize itself.

Two seriously ill persons have so far died after receiving flu vaccine. One of them is a man of Vasternorrland who had a heart attack. MPA can not say if his death is a reaction to the vaccine. An autopsy will be done to clarify the cause of heart attack.

"It is very difficult to assess. Someone may consider that there is a connection. It's a personal thing how to assess," says Lennart Walden Lind, doctors at the MPA.

Fem har dött efter vaccination

Aftonbladet, 27 Oktober 2009
https://web.archive.org/web/20091029222230/http://www.aftonbladet.se/nyheter/article6026728.ab

Fortfarande oklart om det finns samband

En miljon svenskar har vaccinerats mot svininfluensan.

Fem av dem har dött kort efter vaccineringen.

Nu utreds frågan av Läkemedelsverket.

– Inget pekar på att det finns ett samband, säger Jan Liliemark, på Läkemedelsverket.

Flera personer har dött kort efter att de vaccinerats mot svininfluensan.

De har avlidit mellan 12 timmar och fyra dygn efter att de fick en dos pandemrix insprutat i en muskel.

Nu har siffran stigit till fem.

– Det kommer att tillkomma nya dödsfall, säger Jan Liliemark, professor på Läkemedelsverket.

Fallen utreds

Alla personerna tillhörde någon av riskgrupperna.

Läkemedelsverket håller nu på att gå igenom fallen.

– Vi letar efter mönster, om de har något gemensamt. Vi har inte hittat några tydliga samband mellan dem än.

Inget samband än

Man har ännu inte hittat något som visar att dödsfallen kopplas till vaccineringen.

– Det vi sett hittills visar inga misstankar om samband, säger han.

Men utredningen är inte avslutad. Först om två veckor kommer de ha fått in alla uppgifter de behöver.

Det behöver inte finnas ett samband. Ett antal hundra i riskgrupperna dör inom fyra dygn oavsett om de vaccinerats eller inte.

Allvarlig allergisk reaktion

Det har kommit in ett 100-tal rapporter om biverkningseffekter till Läkemedelsverket.

– Det står inget oväntat i rapporterna. Det är kända och förväntade biverkningar.

Man har däremot fått in ett allvarligt fall.

– En kvinna fick en svår allergisk reaktion i samband med vaccineringen. Eftersom många som inte brukar arbeta med vaccinering gör det nu måste man vara extra noggranna med säkerheten så att de klarar av att häva en sådan allergisk reaktion, säger Jan Liliemark.

Dubbelt så många sjuka

198 personer hade bekräftat svininfluensan vecka 42. En vecka senare var siffran dubbelt så hög.

Nu är det skollov och troligtvis kommer smittspridningen i skolan tillfället stoppas.

– Men det kommer sprida sig i familjen och till föräldrarna, säger Johan Carlson, generaldirektör Smittskyddsinstitutet.

THE FLU CASE

Fifth "swine flu" vaccine death in Sweden - vaccinations still go ahead as planned!

The Flu Case, 27 October 2009 12:50
https://web.archive.org/web/20091029221850/http://www.theflucase.com/index.php?option=com_content&view=article&id=1416:fifth-qswine-fluq-vaccine-death-in-sweden-vaccinations-still-go-ahead-as-planned&catid=41:highlighted-news&Itemid=105&lang=en

Media in Sweden is having a tough time maintaining the propaganda as more and more people question the reasons for the mass vaccination. Now, authorities say that if not "80% of the population takes the shot, we risk 100 deaths from the swine flu". Most Swedes know that a normal flu season see several thousand dead from complications from the seasonal flu so the proportions of the propaganda coming from media and the government has caused a growing revolt against the massive attempts to scare people to take the poisonous injection.

We have earlier reported on the first death, the second death (also here), the third death and the fourth death in Sweden from the poisonous Pandemrix vaccin shot.

Today, Svenska Dagbladet reports that over 350 cases of side effects from the Pandemrix "swine flu" shot, has been recorded so far.
=>https://web.archive.org/web/20100131225841/http:/www.svd.se/nyheter/inrikes/artikel_3712585.svd

It has also become clear that this shot contains the most deadly mix of substances of all the known vaccines manufactured against the so called "swine flu" H1N1 influenza. The official number of deaths from the "swine flu" vaccine is now five. And that is only those who have strong immediate reactons, the long term effects are usually never even investigated. If you would die from the shot two weeks after you took it, your death would not be considered to have anything to do with the vaccination. Severe health problems years after will of course be very hard to link to the poisonous injection. Even if these five official cases died within days, the official story is of course as expected: "none of these deaths has been confirmed to be linked to the vaccine".

In Aftonbladet, Jan Liliemark from The Swedish Institute for Infectious Disease Control (SMI) says: "- Nothing points to a connection.
=> https://web.archive.org/web/20091029222230/http://www.aftonbladet.se/nyheter/article6026728.ab

There will be more deaths. We are looking for a pattern, if the cases have something in common. We have so far not found any clear connections between them yet." Officially 198 cases of confirmed "swine flu" exist in Sweden today among a population of over 9 million. How these cases have been tested and determined is not clear.

As always with statistics like this, historically we know that very few of all real side effects are actually reported. Optimistically, up to ten per cent would be reported. It is also highly likely that deaths are being kept secret by the authorities so that the massive and hugely expensive vaccination program will not come to a complete stop. Too many have put their job, reputation and title at stake for the truth to be reported and published.

So far, three people have been reported dead from complications from getting the H1N1 virus. Five dead from the flu shot before the real vaccination campaign has even started should be an indication to question the vaccine and the strategy chosen but the authorities have so much prestige invested that it is unlikely it will ever happen - no matter how many will die from the poisonous injections.

The Swedish public are being kept in the dark about the most simple facts about the vaccinations. The questionable protection against the virus will only be for this present strain - any new mutations would immediately require a new vaccine for that strain. The new second wave of the new mutation is exactly what authorities warn about and use as an argument to take the poisonous injection.

Authorities are running out of arguments and completely idiotic arguments have been published the last week in Sweden. "There is less mercury in the shot than you get from eating mercury contaminated fish", "You might get sick from the vaccine but you should take that risk to ´save" someone who could die from getting the H1N1 infection from you", "It would be like killing someone to not take the shot out of solidarity" and "Mercury is not dangerous and also squalene is not dangerous, there is nothing called the Gulf War Syndrome and if there is, it has nothing to do with squalene because there was no squalene in the vaccines the US troops got", "German politicians will not get a different flu shot than the rest of the German population".

The number of flat out lies are so many, it is hard to keep track of them all.

The chief of The Swedish Institute for Infectious Disease Control (SMI), Annika Linde, says in the article: "- The Vaccine is principally natural to the body. The mercury was necessary but the amounts are very small. There are many who have been making statements without qualified knowledge. It is of course good that this type of matter is debated but some of the reporting is rather devastating for the possibility to vaccinate the whole population." You are welcome Mrs Linde.

The official line in Sweden is bordering to madness and the biggest medical scandal in the history of the nation has just started.

Two more bad reactions to the H1N1 vaccine

VacThruth, 28 October 2009, 1:00 am
https://vactruth.com/2009/10/29/two-more-bad-reactions-to-the-h1n1-vaccine/

The H1N1 vaccine isn't for everyone.

Since the mass immunization began in Winnipeg Monday, two people have had rare allergic reactions to it, according to the Winnipeg Regional Health Authority.

"We have had two incidents involving some allergic-type symptoms," said Dr. Sande Harlos, a WRHA medical officer of health. "This is what we're prepared to deal with."

The maker of the H1N1 vaccine, GlaxoSmithKline, warns that up to one in 1,000 doses may result in an allergic reaction leading to a "dangerous decrease of blood pressure."

"That's why you're asked to wait 15 minutes afterwards," Harlos said. A severe reaction will happen within minutes of getting the shot.

By 3 p.m. Tuesday, 15,695 Winnipeggers had been immunized without incident. When someone reacts badly to the vaccine, there are medical staff on hand to help, Harlos said. The vaccine recipient is taken to hospital to be kept under observation. Harlos said the two people who reacted badly to the vaccine – one on Monday and one on Tuesday – are OK. "They left in good condition."

Meanwhile, Winnipegger Janice Dehod is worried about her allergy to the mercury-based preservative thimerosal used in the vaccine. "I know if it is in eye drops or contact lens preserver, it will make my the skin around my eyes puff up and swell in a really ugly way," she said. "I am not sure what thimerosal will do in my veins."

Harlos said unless someone has a severe egg or thimerosal allergy, they shouldn't have a severe reaction to the vaccine. "Some people have a mild reaction when it's used topically. That isn't the same as a systemic whole-body reaction," Harlos said.

A severe allergic reaction is an anaphylactic response – the throat closes, blood pressure plunges and airways tighten, said Dr. Joel Kettner, Manitoba's chief medical officer of health.

Dehod said she has had an adverse reaction to a flu vaccine in the past, but doesn't know if it contained thimerosal. She wishes Manitoba would obtain vaccine without thimerosal. "I don't want to be one of those people that falls through the cracks and gets H1N1 because Manitoba Health did a pretty good job for most people and gambled with the health of those that are a little more sensitive to preservative."

Mercury downplayed

Thimerosal is a mercury-based preservative. In large concentrations, or over extended periods of exposure, mercury can cause damage to the brain and kidneys. However, the Public Health Agency of Canada says the amount of mercury in the H1N1 flu vaccine is significantly less than in a can of tuna.

The National Advisory Committee on Immunization has recommended a long-term goal of removing thimerosal from vaccines, provided that safe alternatives to this preservative can be found. "This will help to reduce unnecessary environmental exposure to mercury."

CDC States H1N1 Vaccine May Maim and Kill 30,000 Americans, FDA Requires Minimal Efficacy

Global Research, 29 October 2009
https://web.archive.org/web/20091029070249/http://www.globalresearch.ca/index.php?context=va&aid=14950

CDC says to assume 1 in every 100,000 vaccine recipients will suffer serious side effects, FDA only requires vaccine be effective.

The Center for Disease Control and Prevention (CDC) has officially stated that there will be as many as 30,000 serious, potentially lethal adverse reactions to the novel H1N1 vaccine, while the FDA guidelines for the novel H1N1 vaccine only require that it work in 3 out of every 10 recipients.

Last Saturday, I attended one of 10 "public engagement" meetings the CDC is holding across the country, utilizing a new model of public engagement designed to provide a public viewpoint or societal perspective on the topic at hand (mass vaccination) to the sponsor (in this case, the CDC).

Part of the process entails the sponsor (CDC) providing the following: "Information on the many sides of an issue is provided to the participants in a fair and balanced manner so that all participants become well-informed, and the overall group process is convened and managed in a neutral, respectful fashion."

This requirement is met by providing an oral presentation in easy to understand language, a booklet summarizing the key facts needed and a discussion guide summarizing the choices faced.

The assembled group of 80 participants was shown a video, given a brief oral presentation and a printed discussion guide. We were asked to accept several assumptions in considering the topic. We were asked to assume that the severity would be similar to what had already been observed in the spring of 2009; we were told to assume that the vaccination program would be voluntary, not mandatory; we were told to assume that initial vaccine supplies will be available in October but supply would be limited through February 2010.

The most disturbing assumption we were asked to accept dealt with the safety of the novel H1N1 vaccine. In the video, the CDC spokesperson explained that during the 1976 mass vaccination campaign, 1 in every 100,000 recipients of the vaccine developed Guillain Barré syndrome (GBS), a disorder in which the body's immune system attacks the peripheral nervous system often leading to paralysis and death. There is no known cure for GBS.

In 1976 roughly 40 million Americans received the vaccine and some 4,000 developed GBS.

The printed material that was distributed reiterated these horrific statistics and we were asked to accept the assumption that, "the estimated risk for more serious reactions (e.g. Guillain Barré syndrome) is between 1-10 per million persons vaccinated".

This is a less direct way of stating that the risk is about the same as existed during the 1976 mass vaccination attempt and that as many as 1 in every 100,000 recipients will develop GBS or some other

serious adverse reaction. The CDC is setting up a new intensive surveillance system with which to monitor and track GBS cases that result from the novel H1N1 vaccine.

Merriam-Webster defines assumption as a fact or statement taken for granted and assumed to be true. If we accept the documented assumption presented by the CDC, we are to consider it a fact that 1 in every 100,000 vaccine recipients will suffer a serious adverse effect such as GBS.

This means that if the entire U.S. population is vaccinated (a stated goal of the CDC), we are to assume as a fact that 30,000 Americans will suffer debilitating or lethal side effects. Apparently the CDC considers this an acceptable level of collateral damage.

As unthinkable as this is (destroying or ending the lives of as many as 30,000 Americans), that is only part of the story.

The novel H1N1 vaccine being developed must adhere to guidelines set forth by the U.S. Food and Drug Administration (FDA). The FDA has announced that a vaccine will be accepted if it creates antibodies in 4 out of 10 recipients (40%), with at least 70 percent of those 4 achieving an antibody level believed to provide benefit. This means that an acceptable vaccine candidate would provide "protection" for 28% of vaccine recipients (70% of the 40%), or less than 3 in 10 recipients. The requirement drops to 18% efficacy for those over 65 years of age (60% of 30%).

So here are the facts, as documented by the CDC and the FDA:

As many as 30,000 Americans will be harmed by the novel H1N1 vaccine.

The vaccine may be ineffective in more than 7 out of 10 recipients.

And in case you think I am alone in my concerns, here is what several vaccine experts associated with the CDC and the U.S. government say on the subject.

"I am very skeptical of finishing vaccine before we know the appropriate dose to be included in each inoculation, before immunogenicity studies are complete, or before safety assessments have been finished," William Schaffner, MD, Chairman of the Department of Preventive Medicine at Vanderbilt University and a member of the CDC Advisory Committee on Immunization Practices (ACIP), wrote in an recent e-mail.

"We have assured both the profession and the public that the H1N1 vaccine will be evaluated with the same rigor that is applied to seasonal vaccine. We should NOT make vaccine available before the trials are complete and the results carefully assessed."

Others are worried about a repeat of the last swine flu "pandemic," now regarded as a public health and public relations debacle.

"I fear that a rush towards vaccinating the population without completing trials risks leading to the harmful outcome that we witnessed during the 1976 swine flu scare, where the government advocated rapid production and vaccination of the population without adequate safeguards, which led to an unexplained increase in cases of Guillain Barré syndrome (GBS), amongst other complications, and massive liability for the government," wrote Amir Afkhami, MD, PhD, of George Washington University, an international expert on the 1918 Influenza pandemic and an advisor to the U.S. State Department, the U.S. military, and the World Bank on issues pertaining to infectious diseases, public health and, mental health.

"I think in this regard, we must learn from lessons of the past and be mindful of not jumping from the proverbial frying pan into the fire by putting people's health at risk without adequate production and safety monitoring of the vaccines."

THE FLU CASE

Johan Niklasson

More unconfirmed deaths from the "swine flu" vaccine

The Flu Case, 30 October 2009

https://web.archive.org/web/20091104054807/http://www.theflucase.com/index.php?option=com_content&view=article&id=1515:more-unconfirmed-deaths-from-the-qswine-fluq-vaccine&catid=41:highlighted-news&Itemid=105&lang=en

We keep getting reports from severe side effects from people who have been injected with the poisonous "swine flu" vaccines.

In Sweden, media is now no longer reporting on side effects and the recent deaths of several "swine flu" vaccination victims are being completely blacked out from the daily reporting on the "horrible swine flu".

We just received this e-mail, one of several similar we receive every day now:

My bestfriends husband just died
We were telling him not to take the flu shot or the h1n1 shot and he did take the shot this am today oct 29th 2009 9.30 est died at apx 4.00pm cant confirm nothing yet but im just passing this along... I just wish he would of not taken it everyone told him not too!!! Pretty sure it was just the flu shot so they say..not certain on that will be investgating as best as i can,
Take care be safe .. K

It is highly likely that the massive propaganda campaigns now underway in many countries intentionally clock any news on negative side effects and deaths - it is a logical part of the propaganda campaign and since almost no news papers report on these many cases, it is clear the reporting is strictly controlled from "above". We have also received unconfirmed information of several more deaths in Sweden (part from the five already reported).

The Telegraph

Rebecca Smith and Kate Devlin

People will die after swine flu vaccine - but it's just coincidence

Telegraph, 31 October 2009, 8:00 AM.
https://web.archive.org/web/20091103014827/https://www.telegraph.co.uk/health/swine-flu/6467984/People-will-die-after-swine-flu-vaccine---but-its-just-coincidence.html

Six people in Britain can be expected to die suddenly after having the swine flu vaccine but it will just be coincidence, researchers have said.

With millions of people being vaccinated against the virus there is a real risk that coincidental events will be seen as reactions to the jab, a paper in The Lancet said.

Experts at Cincinnati Children's Hospital in America calculated the background rate of conditions that may be mistaken for vaccine reactions and warned that there is a risk people will shun the jab needlessly.

Only if these background rates are exceeded will it point to a potential problem with the vaccine.

Medical experts have been told to watch for any cases of Guillain-Barré syndrome during the flu pandemic as some research suggested there was a link between a flu vaccine used in America in 1976 and the condition, in which the body's immune system mistakenly attacks part of the nervous system and can be fatal in rare cases.

However flu itself it also linked to the condition and about one in every 100,000 people a year.

Dr Steven Black and colleagues calculated that if 10 million people in Britain were vaccinated there would be around 22 cases of Guillain-Barré syndrome and six cases of sudden death would be expected to occur within six weeks of vaccination as coincident background cases.

Just over nine million people in priority groups, such as pregnant women and those with long-term illnesses, and another two million front line health and social care workers will be offered the vaccine in Britain over the next two months.

Decisions will be taken soon over whether to offer the vaccine more widely.

The research also suggested that 397 per one million vaccinated pregnant women would be predicted to have a spontaneous abortion within one day of vaccination.

But this is the rate of spontaneous abortion that would occur on any given day out of a group of one million pregnant women during a vaccination campaign or not.

Dr Black wrote: "Misinterpretation of adverse health outcomes that are only temporally related to vaccination will not only threaten the success of the pandemic H1N1 influenza vaccine programme, but also potentially hinder the development of newer vaccines.

"Therefore, careful interpretation of vaccine safety signals is crucial to detect real reactions to vaccine and to ensure that temporally related events not caused by vaccination do not unjustly affect public opinion of the vaccine.

"Development and availability of data banks that can provide locally relevant background rates of disease incidence are important to aid assessment of vaccine safety concerns."

The researchers said although scientists know that events connected only be time does not prove cause and effect, the cases 'nonetheless raise public concern'.

Prof David Spiegelhalter, Winton Professor of the Public Understanding of Risk, University of Cambridge and Co-Director of Straight Statistics, said: "What a fine paper. If millions of people are vaccinated then just by chance we can expect bad things to happen to some of them, whether it's a diagnosis of autism or a miscarriage.

"By being ready with the expected numbers of chance cases, perhaps we can avoid overreaction to sad, but coincidental, events. And why don't we ever see a headline 'Man wins lottery after flu jab'?"

Professor Robert Dingwall, University of Nottingham, said: "The difference between cause and coincidence is difficult enough for specialists to grasp, let alone the wider public.

"However, this paper is very important in spelling out the fact that just because two events happen at the same time, they are not necessarily related. There is a background rate of death, disease and accidents that happen all the time regardless of what medical interventions are going on.

"Confusing cause and coincidence may lead to serious policy mistakes that put people unnecessarily at risk.

"I am sure that some coincidences will emerge from a high-profile vaccination campaign and we must be careful not to be misled by them."

Meanwhile the World Health Organisation said that pregnant women could be immunised with any of the vaccines licensed for use against swine flu.

Dr Marie-Paule Keiny, from the WHO, said: "Sage (the Strategic Advisory Group of Experts) has concluded that the safety profiles are good and recommend that pregnant women can be immunised with any of the licensed vaccines.”

The WHO also recommended that one dose was sufficient to immunise children.

WAZ

Fünf Tote in Schweden nach Schweinegrippe-Impfung

The Westdeutsche Allgemeine Zeitung (WAZ), 31 October 2009, 21:32
https://www.waz.de/panorama/fuenf-tote-in-schweden-nach-schweinegrippe-impfung-id42855.html

Frankfurt/Main. Nach Berichten über tödliche Folgen der Schweinegrippe-Impfung haben schwedische Behörden erstmals einen Bericht dazu veröffentlicht. Demnach starben dort bis dato fünf Personen nach einer Impfung. Bei 37 Patienten wurden allergische Reaktionen gemeldet, 15 davon waren schwer.

In Schweden wird nach Angaben des Paul-Ehrlich-Instituts (PEI) seit dem 12. Oktober mit dem auch in Deutschland verwendeten Schweinegrippe-Impfstoff Pandemrix geimpft. Inzwischen hat die schwedische Arzneimittelbehörde Informationen zu den bisher gemeldeten Verdachtsfällen von unerwünschten Nebenwirkungen der Impfung veröffentlicht.

Pandemrix steht in der Kritik, weil es Adjuvanzien, also Wirkstoffverstärker, enthält, um das Immunsystem noch mehr anzusprechen und mehr Dosen aus derselben Menge Material zu erhalten. Wegen der Substanzen kommt es häufig zu Nebenwirkungen wie Schmerzen an der Injektionsstelle, Hals- und Kopfschmerzen, Schwindel, übermäßiges Schwitzen, Gelenk- oder Muskelschmerz, Schüttelfrost, Ermüdung und Fieber.

Fünf Tote nach Impfung

Nach Angaben des PEI, das in Deutschland für die Impfstoffzulassung zuständig ist, wurden in Schweden bisher etwa 1,4 Millionen Dosen Pandemrix ausgeliefert, wieviele davon bereits verimpft wurden, teile die schwedische Behörde nicht mit. Insgesamt habe die Behörde bisher 600 bis 700 Meldungen von Verdachtsfällen unerwünschter Nebenwirkungen erhalten. Dabei weiche das Spektrum von Nebenwirkungen nicht von dem Spektrum ab, das in klinischen Studien beobachtet wurde.

Im zeitlichen Zusammenhang mit der Impfung starben demnach fünf Patienten, derzeit gebe es aber keine Hinweise auf einen ursächlichen Zusammenhang mit der Impfung. Zwischen Impfung und Tod hätten je nach Fall zwölf Stunden bis vier Tage gelegen. Alle fünf Patienten hatten demnach chronische Erkrankungen, drei waren älter als 74, die anderen beiden zwischen 54 und 65 Jahre alt. Weitere Informationen zu den Todesursachen werden demnach eingeholt.

Auch anaphylaktische Reaktionen

Als beachtenswert bezeichnet das PEI, dass bei 37 Patienten allergische Reaktionen gemeldet wurden, 15 davon waren schwerwiegend. Nach Angaben der schwedischen Behörde habe es vier anaphylaktische Reaktionen in ursächlichem Zusammenhang mit der Impfung gegeben, in einem fünften Fall sei kein ursächlicher Zusammenhang festgestellt worden. In keinem Fall aber sei es zu einem anaphylaktischen Schock gekommen. Bei zwei Patienten sei eine Allergie gegen Hühnereiweiß bekannt gewesen, dabei habe es zumindest bei einem Fall eine anaphylaktische Reaktion gegeben.

Unter einer anaphylaktischen Reaktion versteht man eine schwere allergische Sofortreaktion, die meist überraschend als Überreaktion bei Kontakt mit einer Allergie auslösenden Substanz auftritt. Laut PEI sind solche Reaktionen nach Impfungen ausgesprochen selten, man schätzt, dass pro einer Million Dosen ein bis zehn Fälle auftreten.

Die Umstände der einzelnen Fälle müssten weiter abgeklärt werden, empfahl das PEI. Zudem solle bei Personen mit bekannter Hühnereiweißallergie die Indikation einer Impfung gegen Schweinegrippe sehr sorgfältig gestellt werden. (ap)

Protecting its patients from the flu at health facilities is more important than the personal health choices and privacy of its health care personnel at those facilities. Even assuming health care personnel compliance *is* established, it will be reluctant, and at a cost. Deviance can be expected in terms of receiving the vaccination due to diminished appraisals of legitimacy of the state and those institutions cooperating with the policy. This law simply cannot produce enough positive consequences to outweigh the effort and side effects required to sustain it.

In sum, these four components render New York's recent public health law as *health promotion theater,* an illusionary solution to a socially constructed health problem. The law is correctly labeled by its authors as an "emergency regulation," because it is a reactionary response to the moral panic created by the H1N1 virus. Devoid of any precedence, it sprang up with overwhelming public support and acceptance, and policymakers pushed forth until its adoption. It undoubtedly appeals to various mythical narratives, such as life, good health, survival, self-preservation, and saving lives. Lastly, its overall success is unforeseeable. It will likely fail on account of unexpected consequences; such as noncompliance, high monetary costs associated with the manpower necessary to sustain it, and the negative effect it may produce on the work cultures where implemented.

Alternative Solutions

Given the above mentioned issues with the new law, a false illusion of health care promotion is created. As with any social issue that leads to *health promotion theater*, there are no easy solutions. However, if New York officials are adamant about vaccinations being the solution to the influenza problem, they ought to consider alternative ways of achieving their ultimate goal of vaccinating health care personnel. New York, as well as other states considering following suit, ought to consider implementing these more effective alternatives that do not result in high monetary costs, unnecessary manpower, and negative changes in the work culture. To our knowledge, the alternatives suggested below are not currently practiced in any health setting for the purpose of increasing vaccination rates. However, they have succeeded in motivating behavior change in other settings, as reported by each of the respective references.

Making vaccinations optional and offering rewards for those health care personnel who receive vaccinations could boost vaccination rates without the negative effects described above. Such voluntary recruitment attempts are certainly not a novel idea, and many have been utilized by officials in the past without significant effect.[1] However, the method suggested here is based on two of the six most powerful principles of influence: reciprocation and consistency.[2] Tendencies toward reciprocation, the first principle, are observed across all societies. Reciprocation is the normative gesture of repaying what one has received, be that a reciprocal exchange of gifts, favors, or invites. The reciprocation principle does not only refer to tangible items. Consistency is the second principle, introduced as the notion that public commitments predict future action. Even minor verbal agreements positively influence the likelihood of following through on intentions. These two principles can be merged in such a way as to significantly boost health care personnel vaccination rates.

Traditionally, when offering rewards to people, individuals are asked to *first* meet a requirement (i.e., getting the vaccine) *in order to* get a promised reward. Building off of reciprocation research,[3] however, it is worth trying the opposite; *first* giving individuals a reward or gift and then anticipating their reciprocation (seeking vaccinations). To buffer the vaccination success rate, health facilities should also utilize the second principle of influence, consistency. This principle can be employed simply by asking for commitments, especially public commitments or promises, prior to distribution of the reward/gift stating that the individual *does* plan on following through with his/her vaccination

(as a sort of oath to reciprocating the gift). As this will take place in a public setting, the personnel will be held accountable to each other in following through on their commitment. Thus, no oversight is necessary (as people will be socially motivated and held accountable by those whom they care to preserve their reputation in front of).

This method is quite simple. An announcement could be made during a staff meeting about the importance of vaccination, asking the group to seek the shots. The announcement would be followed by asking for an informal public agreement/confirmation succeeded by the distribution of a small in-advance thank you gift to those present. Although there is a gift involved, the focus is on fulfilling the commitment and the gift's reciprocation. Yet, there are no "one-size-fits-all" rewards that will equally motivate all health care personnel to take the effort of seeking vaccinations. Thus, luring personnel with the promise of delivering a gift *upon* their vaccination is a less appealing and less effective method, as it is contingent on the gift's value to each individual. Utilizing this principle, however, the focus is not on the reward, but on enforcing the socially accepted norms of reciprocation and consistency (to which there is generally a stronger pull towards than there may be to an arbitrary gift). With that said, it matters very *little* what the actual rewards are. Each facility could come up with its own reward ideas. The rewards could be low-cost items such as holiday items, movie tickets, gift cards, or items donated by a company. Such prizes would be less costly than the manpower required by the law to ensure that each staff member is up-to-date on his or her annual vaccinations. Additionally, as opposed to feeling forced to seek vaccination, employees would feel rewarded for doing so.

Health related incentives would be another appropriate means of encouraging health care personnel to seek vaccinations. These incentives could include offering lower insurance co-pays or deductibles for those health care personnel who choose to get vaccinated. Granted, this solution would also require some manpower, but the anticipated satisfaction and positive attitudes among health care personnel in response to these incentives would far outweigh the energy required to sustain such a program. Given that more than three out of four people report being dissatisfied with the cost of health care,[4] this type of incentive has never been more appropriate than now. Given these attitudes, it is likely that health care related incentives would motivate many to seek vaccinations.

Lastly, an entirely free way to promote influenza vaccinations would be to provide seemingly small *group* enticements that are tailored to be meaningful to each individual health care institution. Sometimes motivators targeted at the individual may not be as effective as creating a competitive group atmosphere where *groups*, rather than *individuals*, are challenged with a task. Research on social identity theory shows that intergroup behavior is motivated by an effort between groups at promoting and protecting their positive distinctiveness from other groups, which ultimately leads to secure a positive social identity.[5] This phenomenon occurs because group membership leads to an evaluation of individuals' selves through their social identity, and that often translates to heightened self evaluations as a result of the group experience. This principle can be applied to boost vaccination rates.

Groups need not be artificially created, as various groups (e.g., different specializations, shifts, floors, sections, and units) already exist at health facilities. Upon drawing a criterion that divides the facility into any given number of groups or teams, the goal must be stated (the highest percentage of group member vaccinations). Then there needs to be an established prize for the winning group/team that ought to be meaningfully tailored by each facility. For example, if employee parking happens to be a hassle, whichever group obtains the highest vaccination rate could be assigned closer parking spaces for a limited time. Other rewards could include relaxed dress codes, longer lunch breaks, or donations to the group's choice of charities. These options constitute a low-effort, fun, and enjoyable means of promoting higher vaccination rates *alongside* of building team morale and social validation among the health care personnel.

All of these proposed rewards, incentives, and enticements would achieve the law's goal of increasing the number of vaccinated personnel, *without* negatively impacting the work atmosphere or diminishing the perceived choice over their personal health. Rather, these suggested alternatives would build group solidarity alongside of health awareness, ultimately leading to more satisfied employees and better-served patients.

Avoiding Health Care Promotion Theater

The suggestions above can help promote flu vaccinations within facilities. However, the broader issue is the general prevention of laws that are mere *health promotion theater.* In other words, the question at hand is, "How can we prevent health care policies that only *appear* to tackle an issue, but do little to actually solve it?" The primary way to do this is by educating policymakers, as they are the ones who ultimately create mandates and laws. It is unreasonable to expect politicians to be experts in all fields. Therefore, the responsibility of disseminating applicable knowledge and new research falls on experts in all disciplines. Cynical researchers and experts in all fields ought to not only speak up, but should contact their policymakers. When an issue or "moral panic" arises, academics and experts in that discipline should write letters, initiate dialogue, and publish their research through venues accessible to the target politicians. This may mean launching interdisciplinary dialogue and networking outside of comfort zones. Experts on a hot-topic issue that is on the brink of causing social alarm ought to be proactive in contacting, and even trying to meet officials for the purpose of disseminating their knowledge. For many in academia, this translates to a shift from policy critiquing to active involvement in policy formulation. All of this ought to be done in a timely matter, *during* rather than after policy formulation, as hindsight criticism does little to impact policy.

Public policy centers can also help by sponsoring seminars which provide neutral, unbiased research for policymakers. This could be modeled after 'family impact seminars,' which have successfully educated policymakers about a wide range of issues in various states.[6] Experts from around the country would gather and present their research in order to help policy makers make the best possible decisions. While policy making bodies likely do some sort of cost/benefit analysis for most mandates and laws, such seminars will provide an unbiased, broad, and multi-disciplinary array of monetary, as well as intangible research-based costs and benefits. Likewise, it would be appropriate for public policy centers, research institutes, or special interest groups to create public service announcements about potentially alarming issues that may be blown out of proportion by the public, triggering hasty legislation. For example, had a union or association of nurses or physicians sought out a way to thwart the inflation of public concern about H1N1, Subpart 66-3 may not have been implemented. Educating the public along with policymakers is the ideal way to craft policy.

Unless experts speak up in time, *health promotion theater*-like policies will continue emerging out of reactionary responses, and premature actions will be utilized to address pertinent issues. Legislation ought to be based on facts and research, not emotion. Weighing the costs and benefits ought to take place with qualified experts involved. Ideally, policymakers ought to be the ones calling in the experts and initiating the necessary partnerships; however, this does not always happen, especially in emergency situations. Therefore, the broader message that this article seeks to advance is the importance of researchers and experts broadcasting their knowledge through different publication venues, open seminars, public service announcements, and primarily though seeking out connections with influential policymakers, as opposed to waiting for an invitation to do so.

Conclusion

There is no doubt that illness is a major concern, and that steps should be taken to avoid illnesses or viruses becoming epidemics. Even so, when policymakers hastily enact responses as a result of moral panic, they risk passing policies that are mere *health promotion theater;* that is, policies that have the appearance of addressing a health issue, but actually may be unsuccessful, or even have negative consequences. Thus, while policymakers should consult experts, the experts likewise ought

to seek out policymakers and offer their knowledge and research to help fully evaluate the pros and cons of proposed policies, and ultimately work together toward avoiding the enactment of *health promotion theater.*

Oslo-kvinne død tre dager etter svineinfluensa-vaksinering
Oslo woman dies three days after swine flu vaccination

VG NETT, 2 November 2009, kl. 14:01
http://www.vg.no/helse/artikkel.php?artid=588068

En kvinne i 20-årene fra Oslo døde lørdag, tre dager etter å ha blitt vaksinert mot svineinfluensa. Det er så langt ikke grunn til at hun døde av selve vaksineringen.

Det opplyser Statens legemiddelverk en pressemelding.

Kvinnen i 20-årene hadde en underliggende hjertesykdom, som dermed plasserte henne i risiko-gruppene for svineinfluensa. Det var også bakgrunnen for at hun onsdag 28. oktober ble vaksinert for viruset.

Tre dager senere, lørdag 31. oktober, døde hun uventet. Foreløpige undersøkelser viser ingen sammenheng mellom dødsfallet og vaksinen, men fordi det inntraff så tett opp mot vaksineringen ble kvinnen obdusert så raskt som mulig.

- Vi mener at dødsfallet ikke har noen sannsynlig sammenheng med vaksinen. Dette dødsfallet skjedde uventet lørdag formiddag, og vi har i løpet av helgen fått utført obduksjon. Alle resultatene foreligger ikke med en gang, men resultatene vi har hittil tyder ikke på noen sannsynlig sammenheng, sier avdelingsoverlege Steinar Madsen Statens Legemiddelverk til VG Nett.

Ifølge Legemiddelverket skjer dødsfall knyttet til vaksiner nesten aldri.

Fortsetter massevaksinasjonen

- Men når man vaksinerer så mange over kort tid vil det naturligvis skje dødsfall som ikke har noen sammenheng med vaksinasjonen, heter det videre i meldingen fra Legemiddelverket.

Dødsfallet får heller ikke konsekvenser for norske helsemyndigheters anbefaling om masse-vaksinasjon av landets befolkning.

Legemiddelverket har et løpende samarbeid med europeiske legemiddelmyndigheter når det gjelder sikkerheten av vaksinen.

Så langt er rundt 500.000 doser av vaksinen Pandemrix sendt ut, og rundt 300.000 personer er vaksinert. Det er tilsammen rapportert om mulige bivirkninger på åtte personer.

Young Norwegian woman dies after getting the "swine flu" vaccine

The Flu Case, 2 November 2009, 19:06
https://web.archive.org/web/20091106021139/http://www.theflucase.com/index.php?option=com_content&view=article&id=1561:young-norwegian-woman-dies-after-getting-the-qswine-fluq-vaccine&catid=41:highlighted-news&Itemid=105&lang=en

The Norwegian news paper VG reports that a woman in her twenties died just three days after receiving the "swine flu" shot. Of course they also report that she had a "underlying hart disease" which more than likely will be blamed for her death. This is a pattern that by now is clearly recognizable. This comment from one of our readers sums it up well: "Funny how when someone dies of swineflu with a pre-existing condition they died from swineflu - no question. And if someone dies from the vaccine with a pre-existing condition they died from the pre-existing condition - no question."

So far, about 300 000 people in Norway have been and over 500 000 doses of the poisonous Pandemrix "swine flu" vaccine has been distributed in Norway.

HD

Tore Scherstén

Oroande tyst i Sverige

Helsingborgs Dagblad (HD), 2 November 2009, 07:02
https://web.archive.org/web/20100123013802/http://hd.se/ledare/2009/11/02/oroande-tyst-i-sverige/

Det har varit ovanligt tyst om potentiella risker för oönskade biverkningar med vaccinet Pandemrix, skriver professor Tore Scherstén, Båstad.

Debatt. **Under hösten** har massmedier och myndigheter, främst Läkemedelsverket, Socialstyrelsen och Smittskyddsinstitutet, fört en intensiv kampanj för att förmå svenska folket att vaccinera sig mot svininfluensan (A/H1N1). Olika argument har anförts i kampanjen – från skrämsel till solidaritetsskäl. Solidaritet mot vem eller vad kan man fråga sig – staten, sjukvården eller befolkningen?

Beträffande potentiella risker för oönskade biverkningar med vaccinet (Pandemrix) har det varit ovanligt tyst. Trots att riskerna för biverkningar har diskuterats intensivt i flera andra länder.

I ett tidigare debattinlägg i HD har jag framfört tveksamheter med de immunförstärkande tillsatserna, squalen och tokoferol, i vaccinet som distribueras i Europa Dessa tillsatser kan ge upphov till sjukdomar på grund av autoimmunitet, till exempel ledgångsreumatism. I USA är vaccin med dessa tillsatser förbjudna på grund av sådana risker.

I Tyskland har oron över säkerheten med vaccinet (Pandemrix), som erbjudes allmänheten blivit mycket stor sedan det genom en artikel i *Der Spiegel* blev känt att toppolitiker och regeringsanställda tjänstemän erbjudes ett alternativt vaccin utan dessa tillsatser (Celvapan).

Michael Kocher, president vid det Tyska kollegiet för allmänpraktiserande läkare och familjeläkare, anser att vaccinet är otillräckligt prövat för att ges i varje fall till barn och gravida kvinnor. Han vaccinerar inte sig själv och rekommenderar läkarna i sin organisation att inte vaccinera några patienter eftersom de potentiella riskerna enligt honom överväger den möjliga nyttan.

Wolf-Dieter Ludwig, ordförande för den Tyska Medicinska Associationens läkemedelskommission, har beskrivit hela vaccinationsprogrammet som en skandal, Han anser att den tyska regeringen blivit alltför eftergivlig till läkemedelsbolagets krav och bunden till tidigare ingånget kontrakt om köp av vaccin.

Efter dessa avslöjanden om speciellt vaccin till vissa och om riskerna visar en intervju-undersökning att endast 12 procent av tyskarna avser att vaccinera sig.

Dessa förhållanden i Tyskland har rapporterats i detalj i en artikel i den mycket väl ansedda medicinska tidskriften *TheBritish Medical Journal (BMJ, October 21)* med kommentarer och efterföljande diskussion.

Varför är det så tyst här i Sverige med denna för allmänheten så viktiga information från USA, Tyskland och England? Finns det en dold begränsning av yttrandefriheten i känsliga frågor av betydelse för hela nationen?

THE FLU CASE

Swedish professor: "**Is there a hidden and secret limitation of the freedom of speech regarding damages from the flu vaccine**?" – The Flu Case, 21 November 2009, 18:23
https://web.archive.org/web/20100102040757/http://theflucase.com/index.php?option=com_content&view=article&id=2019%3Aswedish-professor-qis-there-a-hidden-and-secret-limitation-of-the-freedom-of-speech-regarding-effects-from-the-flu-vaccineq&catid=1%3Alatest-news&Itemid=64&lang=en

In the news paper HD, Professor Tore Scherstén says he is worried about the complete silence in Swedish media regarding side effects from the poisonous "swine flu" vaccine, Pandemrix, which is being used against the population in Sweden. He notices that in many countries, there has been at least some public debate in media about the safety of the vaccines but in Sweden, the mass vaccination propaganda is met by - nothing.

Many in Sweden wonder what is going on since every main stream media outlet completely black out any information about side effects and deaths from the vaccinations. "Why is it so silent in Sweden" asks the professor, "Is there a hidden and secret limitation of the freedom of speech regarding these issues?"

THE FLU CASE

Swedish media cover up reports on more deaths from the vaccine

The Flu Case, 2 November 2009, 17:27
https://web.archive.org/web/20091105015250/http://www.theflucase.com/index.php?option=com_content&view=article&id=1558:swedish-media-no-longer-reports-on-more-deaths-from-the-vaccine&catid=1:latest-news&Itemid=64&lang=en

The reports of serious side effects including five deaths was openly reported in Swedish media, even if it never received any prominent place in the daily propaganda wave. After the five first deaths, it became completely silent regarding side effects - suspiciously silent. =>
https://web.archive.org/web/20091029221850/http://www.theflucase.com/index.php?option=com_content&view=article&id=1416:fifth-qswine-fluq-vaccine-death-in-sweden-vaccinations-still-go-ahead-as-planned&catid=41:highlighted-news&Itemid=105&lang=en

Now reports of dead and severely injured instead spread from bloggers and other private people who feel the need to warn their fellow citizens.

One blogger posted this yesterday:
I just received this e-mail from a close collegue of mine!
Hello Zarah, I hope all is well with you :)
I know you have been working for informing about the vaccine and its contents. I spoke yesterday with a friend who was completely devastated. A friend of hers had been getting the vaccine (she was pregnant) and she fell seriously ill shortly thereafter. It became so bad that her heart stopped and she died. It is not proven it was the vaccine, but obviously suspected of course, since she fell ill so quickly after the vaccination. Another friend of mine was vaccinated the same day, she is also pregnant. That woman was yesterday in the hospital with severe bleeding. Also that shortly after the vaccination. Scary stuff this.

If this story is true, it confirms information we have received that authorities and media in Sweden no longer reports on several more deaths that has occured the last days.

Here is another story from a Swedish reader:
My sister-in-law took the vaccine a week ago, right after she became severely ill, she is 5 mo pregnant, amnoic fluid started leaking, she is currently in the hospital since a week back. She has to stay there and lay still (to prevent miscarriage I assume?- my comment)

THE FLU CASE

The silence about vaccine deaths in media is due to the contracts with the vaccine manufacturers

The Flu Case, 2 November 2009, 21:37
https://web.archive.org/web/20091106014444/http://www.theflucase.com/index.php?option=com_content&view=article&id=1560:the-silence-about-vaccine-deaths-in-media-is-due-to-the-contracts-with-the-vaccine-manufacturers&catid=41:highlighted-news&Itemid=105&lang=en

This is from a comment made by one of our readers to the article about the silence in Swedish media over recent "swine flu" vaccine deaths:

GSK secret contract binds Government to SILENCE!

Dr Eric Beeth 2009-11-02 18:13:41

Dear all,

I am a Swedish general practioner working in Belgium, and quite involved in this issue, as together with three citizens and another GP we advised the Belgian Government last Friday in court that this is a disguised pharmaceutical trial on human subjects, with real risks involved.

I put in two comments on the story (see below), that are quite relevant in the context that the Swedish Newspapers have seemingly stopped reporting the intermediary results of this disguised pharmaceutical trial.

If you can read French, you will discover at *http://www.lepoint2.com/sons/pdf/vaccin-H1N1%20 medias.pdf* that the maker of PandemRix, that is used in Sweden, passed a secret contract, the same in every European country, which specified a "Green List" of what the government MAY communicate (hardly anything!) and the "Red List" of what may absolutely NOT be made public, like intermediary results of the side effects that appear in the studies of the controversial squalene (and thiomersal) adjuvantated PandemRix until they have been sanitized by Glaxo Smith Kline researchers, and published by GSK themselves.
[See: Marché public n° EPRUS/09-36 relatif à l'acquisition de vaccins contre e-virus HINI passé sur le fondement de l'article 3-7° du Code des marchés publics issu du décret np 2006-975 du 1er août 2006, entre L'Etablissement de préparation et de réponse aux urgences sanitaires (EPRUS) sis 21 avenue du Stade de France, 93210 Saint-Denis La Plaine, Dûment représenté par Monsieur Thierry Coudert, Directeur général... etc.]
=> https://web.archive.org/web/20110917190018/http://www.lepoint2.com/sons/pdf/vaccin-H1N1%20medias.pdf

These contracts also confirm what was announced in Sweden in October, that these pandemic vaccines where actually ordered already back in 2006: there was a standing order to foresee a vaccination for large parts of the population IF the WHO would declare a PANDEMIC of degree 6. When the "New-Type" A/H1N1 appeared, and it started spreading to other continents, the WHO changed their definition of grade 6 pandemic by dropping the criteria that it should be highly deadly. Thus, the government discovered that it's signed standing orders were passed simply to combat a new (designer!) strain of flu that may or may not become more or less lethal than the common Influenza A or B flu.

This has allowed GSK to do a large scale tolerance experiment of their specialy formulated AVIAN-flu vaccine "Pre-PandRix" paid for by the governments, where doctors are recruited for a large scale pharmaco-vigilance study, without being paid as researchers, and patients receive government propaganda to sign up "to protect the weak in our society", while de facto subjecting

themselves to be guinea pigs in this "H1N1-dry-run" study for the future benefit of registering GSK's AVIAN flu vaccine "Pre-PandRix".

If you are to receive the "Pandremix" against the benign "new-type" H1N1-flu this season, we recommend that you first learn about the possible side effects, as GSK asked their own employees to sign an "informed consent form" before receiving the vaccine:

see: http://www.asanat.org/Declaration_of_Free_and_Informed_Consent.pdf or https://web.archive.org/web/20091122094339/http://www.asanat.org/Declaration_of_Free_and_Informed_Consent.pdf

Best regards,
Dr Beeth www.asanat.org
(See also my other comment below)

By the way:
Yesterday, Sunday, I appeared on a TV debate show together with an H1N1-veterinarian vaccine developer at GSK who was very proud to announce that 8000 pregnant women had already been vaccinated in Sweden with no problem what so ever! See middle of this episode:
http://www.rtbf.be/tv/revoir/detail_mise-au-point?uid=38287439668&idsh edule=91a4a97001a0e74752b9267563767a3e
That is the "GSK-sanitized" version of the truth. What is the real situation in Sweden, and what LONG TERM sicknesses will these women/children develop from the experimental vaccine trial?

These contracts were labeled "secret defense":
Dr Eric Beeth 2009-11-02 15:58:33
These contracts were labeled "secret defense", and we learn a lot about "who is the boss, Government, or Big Pharma?" by reading them! You can still access them here: Keep them on your computer, they are historic! http://www.lepoint2.com/sons/pdf/vaccin-H1N1%20medias.pdf
=> https://web.archive.org/web/20110917190018/http://www.lepoint2.com/sons/pdf/vaccin-H1N1%20medias.pdf

Precision
Dr Eric Beeth 2009-11-02 16:37:08
When re-reading my post, I realize that some may become confused about Pre-PandRix or PandemRix.
Pre-PandRix received a temporary and conditional Market Authorization back in 2008 to combat H5N1 bird-flu which is indeed highly deadly, if it should become transmissible to humans. The condition was (1) presence of a grade 6 pandemic, and (2) a bi-weekly intensive post market release farmaco-vigilance study of the side effects, as they appear. When the H1N1 level 6 pandemic was declared, (thanks to an arbitrary decision to drop the criteria of high mortality rate) GSK saw a window of opportunity to use its current adjuvans formulation that was designed for the very high risk bird-flu vaccine (which does not work without a heavy duty adjuvans)to mix with the split-virus H1N1 antigen (which is not a highly deadly virus, and does NOT need adjuvans to be effective: just a double dose of antigen is sufficient). This is how the very clumsily formulated "PandemRix" was born, complete with the identical two component military style 10 dose formulation bottles containing a zest of thiomersal, which increases its toxicity, and makes an "in tempore" mixing with the squalene emulsion necessary. It must be thrown away 12 hours within mixing; otherwise it becomes even more toxic. Even though thiomersal is a considered a neuro-toxin of the past in European countries, and squalene has never been tried out on children, pregnant women, or people suffering from diverse (auto-immune) diseases, the EMEA granted the same conditional market authorization for the formulation against the benign H1N1 (which does not require adjutants or thiomersal) as it had done for the much more dangerous pandemic situation of a bird-flu. The untested vaccines themselves, whether PandemRix or Pre-PandRix, are potentially just as dangerous - time will tell us, thanks to the volunteers who were willing to try out this experimental vaccine. If you or friends are willing to help the advancement of science with this endeavor, please first make sure to sign your informed consent form:
Best regards,
Dr Beeth

The Green List in English
Teemu Valimaki 2009-11-02 19:24:37

Green List
In particular the following information shall not be deemed to be Confidential Information:
a) The Pandemic Vaccine is a 2 component vaccines
b) The fact that the Pandemic Antigen Component is cheaper than the Adjvuant Component
c) Reservation of and number of Doses of Pandemic Vaccine
d) Delivery after Regulatory Authorisation
e) Delivery without Regulatory Authorisation in case of pandemic threat
f) Production place: Pandemic Vaccine will be produced in Germany and Belgium
g) Pandemic Vaccine will be approved by the Competent Regulatory Authority and EU authority
h) Duration of Agreement
i) General statement re development plan: "GSK is closely working together with experts from TILL during the entire contract period"

Red List :
The following information concerning the transaction cited in this document are subject to confidentiality:
a) All of the text of this document and its annexes, with the exception of the element listed in the "Green List, paragraph 1.2.
b) The price per dose.
c) The price per component.
d) The characteristics of the vaccine (as opposed to the standard description "The new adjuvented H1N1 vaccine."
e) Any detail or reference to the agreements of GSK and a third party.
f) Any detail concerning the development plan, including the intermediary or final results of the clinical trials, before thee have been published by Glaxo Smith Kline.
g) Any information concerning the pharmacovigilance (Note from the translator: in this case, we are talking about the reported side effects that are collected after the product has received it's Emergency Use Authorisation clearance) with the guarantee that this clause does not interfere with the rights and obligations of the local competent authorities in conducting their legal obligations.
h) The principles of production of the vaccine (change of production based on the recommendation of the WHO and the vote of the client countries.

THE FLU CASE

GSK admits to serious side effects for AREPANRIX to be used in Canada

The Flu Case, 3 November 2009, 09:43

https://web.archive.org/web/20091106021212/http://www.theflucase.com/index.php?option=com_content&view=article&id=1568%3Agsk-admits-to-serious-side-effects-for-arepanrix-to-be-used-in-canada&catid=1%3Alatest-news&Itemid=64&lang=en

GSK admits to serious side effects in the package insert for AREPANRIX™ H1N1/AS03-Adjuvanted H1N1 Pandemic Influenza Vaccine.

Note: This is written in plain sanitized language as opposed to the adverse effects as seen in the clinical trials which is medical literature. See Page 8 of the insert for adverse reactions in clinical studies to the AREPANRIX™ H1N1/AS03-Adjuvanted H1N1 vaccine.

Side effects and what to do about them

As with all medicines, AREPANRIX™ H1N1 can cause side effects. The very common and common side effects are usually mild and should only last a day or two.

Very common (may occur with more than 1 in 10 doses):

- Pain at the injection site
- Headache
- Fatigue
- Redness or swelling at the injection site
- Shivering
- Sweating
- Aching muscles, joint pain

Common (may occur with up to 1 in 10 doses):

- Reactions at the injection site such as bruising, itching and warmth
- Fever
- Swollen lympth nodes
- Feeling sick, diarrhea

Uncommon (may occur with up to 1 in 100 doses):

- Dizziness
- Generally feeling unwell
- Unusual weakness
- Vomiting, stomach pain, uncomfortable feeling in the stomach or belching after eating
- Inability to sleep
- Tingling or numbness of the hands or feet
- Shortness of breath
- Pain in the chest
- Itching, rash
- Pain in the back or neck, stiffness in the muscles, muscle spasms, pain in extremity such as leg or hand

Rare (may occur with up to 1 in 1000 doses):

• Allergic reactions leading to a dangerous decrease of blood pressure, which, if untreated, may lead to shock. Doctors are aware of this possibility and have emergency treatment available for use in such cases

• Fits

• Severe stabbing or throbbing pain along one or more nerves

• Low blood platelet count which can result in bleeding or bruising

Very Rare (may occur with up to 1 in 10,000 doses):

• Vasculitis (inflammation of the blood vessels which can cause skin rashes, joint pain and kidney problems)

• Neurological disorders such as encephalomyelitis (inflammation of the central nervous system), neuritis (inflammation of nerves) and a type of paralysis known a Guillain-Barré Syndrome If any of these side effects occur, please tell your doctor or nurse immediately. If any of the side effects gets serious, or if you notice any side effects not listed in this leaflet, please tell your doctor.

Serious Warnings and Precautions

Advise your doctor or nurse immediately if you experience these reactions shortly after receiving your injection:

• body rash

• tightness in the throat

• shortness of breath

Swine Flu Vaccine could have major medical Side Effects

Russia Today (RT), 4 November 2009
https://www.dailymotion.com/video/xuacrv
https://www.youtube.com/watch?v=WqjR6XDMi_s

The swine flu vaccine is now being offered in the United States, but many people are worried about the vaccine's potential side effects.

Many say that the vaccine could be linked to the guillain barre syndrome.

RT's contributor and investigative journalist Wayne Madsen attended the international swine flu conference in Washington D.C. and talks about what he learned

Süddeutsche Zeitung

Berit Uhlmann

Tote, Proteste, Mangel

Süeddeutsche Zeitung, 4 November 2009, 10:47 Uhr
https://www.sueddeutsche.de/wissen/schweinegrippe-impfung-tote-proteste-mangel-1.135151

Die meisten Bundesbürger sehen die Impfung gegen die Schweinegrippe mit Skepsis und Verdruss. Ein typisch deutsches Phänomen? Erfahrungen aus anderen Ländern.

Todesfälle in Schweden verunsichern die Welt

Schweden startete als eines der ersten Länder die Massenimpfung mit Pandemrix - jenem Serum, das auch in Deutschland für die breite Bevölkerung vorgesehen ist. Für Verunsicherung sorgten Meldungen über Todesfälle im Anschluss an die Impfung. Nach offiziellen schwedischen Angaben starben fünf Menschen, die Behörden gehen allerdings davon aus, dass die Impfung nicht die Ursache der Todesfälle ist und verweisen darauf, dass jeden Tag mehr als 200 Schweden sterben.

In einem Fall schloss eine Autopsie die Impfung als Todesursache bereits aus, die anderen Untersuchungen laufen noch. Sicher ist, dass alle fünf Betroffenen an chronischen Grunderkrankungen wie Herzkrankheiten und Diabetes litten. Drei von ihnen waren über 75 Jahre alt, die beiden anderen 54 und 65 Jahre.

Mehr als 600 Schweden meldeten bislang Nebenwirkungen der Immunisierung. 20 Fälle stuften die Behörden als schwerwiegend ein. Dabei handele es sich vor allem um allergische Reaktionen.

Insgesamt wurden bislang 1,4 Millionen Dosen Pandemrix in dem skandinavischen Land verteilt, wie viele davon in den Oberarmen der Schweden landeten, ist nicht bekannt.

Schweiz lässt Impfung an Schwangeren und Kindern nicht zu

Die Schweizer Behörden sehen den Impfstoff Pandemrix derart skeptisch, dass sie ihm nur eine eingeschränkte Zulassung erteilten. Das Serum darf nicht bei Schwangeren, Kindern unter 18 Jahren und Erwachsenen über 60 angewandt werden.

Die Zulassungsbehörde Swissmedic begründete ihre Entscheidung damit, dass ihr keine Forschungsergebnisse zur Verträglichkeit in der Schwangerschaft und nur sehr wenige Daten zu Kindern vorlägen.

Der Impfstoff des britischen Pharmakonzerns Glaxo Smith Kline ist umstritten, weil er verstärkende Zusätze enthält, die stärkere Nebenwirkungen als herkömmliche Influenza-Impfungen verursachen können.

Manche Schweizer setzen unterdessen auf eine andere Prophylaxe: Händeschütteln ist in einigen Firmen tabu. Ein Button an der Kleidung weist auf diese Praxis hin.

Germany's mainstream newspaper Die Sueddeutsche says "death, protests and deficits" have characterised the start of the swine flu vaccination campaign. – The Flu Case, 4 November 2009.
https://web.archive.org/web/20091107015055/http://www.theflucase.com/index.php?option=com_content&view=article&id=1590:swine-flu-vaccination-associated-with-death-protests-and-deficits-reports-sueddeutsche-zeitung&catid=1:latest-news&Itemid=64&lang=en

The newspaper notes that at least 5 people in Sweden have died after taking the jab even though the Swedish authorities are denying a connection.

More than 600 Swedes have reported side effects so far. The Swedish authorities say 20 of these cases are severe.

1.4 million doses of GSK's Pandemrix have been distributed in Sweden but it is not clear how many of them have been given to Swedes.

The Swiss regulators have said that Pandemrix cannot be given to pregnant women, children under 18 and those over 60 because there are no clinical data on the vaccine in pregnant women and very little data on the jab in children.

Meanwhile in Austria, Baxter's Celvapan – rushed through for approval without mercury and adjuvants - is to be administerd by government doctors while GPs are t be excluded.

THE FLU CASE

Swine flu vaccination associated with death, protests and deficits, reports Sueddeutsche Zeitung

Defending the right to poison, by Dr Sherri Tenpenn

Infowars, 4 November 2009

https://web.archive.org/web/20091108125339/http://www.infowars.com/defending-the-right-to-poison/

It continually breaks my heart that people have to take a bullet to the head before they find out bullets can be deadly… and they wish they had listened when they were warned not to play with loaded guns.

I have a little person in my office who had 10 rounds of antibiotics and 17 vaccines by 20 months of age. Yes, now autistic. That should be assault with deadly weapons and the doctor should be in jail. Instead, the parents were kicked out of their pediatrician's practice for refusing more vaccines and wanting to get their child well. With these annoying, non-compliant parents out of the way, that doctor can continue to do what vaccinators do: Inject toxic substances into children, ruining their health and the lives of the child's family members.

Parents have had years to get informed; my books and DVDs have been available for years since 2002. Dozens of others have been trying to educate people for as long – or longer – than I have. Parents of vaccine-injured children have implored fellow parents to question vaccines and demand answers. More recently, very visible persons – Jenny McCarthy and Dierdre Imus – have warned about vaccines, begging and pleading with parents to stop – JUST STOP.

I get emails almost every day that say things like, "I got your DVD and your book…but I have a question: should I get a flu shot?" WHAT?!! My mouth drops to the desk and I have to find a way to nicely but firmly say, "No, you should not get the flu shot."

That may seem harsh and pretty bold, but we are coming in to some very turbulent times. Soft language and hand holding is no longer in order. The stranglehold of fear, perpetrated by those in white coats and the medical bureaucrats in Washington DC who take their marching orders from pharma, continues. Funny how they can be the "experts" when it is obvious they don't even understand – and probably don't even read – their own medical literature.

Being in the business of waking people up to the hazards of vaccines certainly has its ups and downs, as many of you know. Today's news was particularly discouraging. The woman bragging that she stood in line for FIVE hours to get an H1N1 shot. Schools vaccinating children without parental consent. Several more miscarriages reported after H1N1 vaccination. The strange outbreak in the Ukraine that the WHO has already declared to be an outbreak of "novel H1N1" – how can that be? And this proclamation will be used to *Really* terrify people into getting vaccinated.

Until my dying breath I will never understand how adamantly people defend their right to inject themselves and their children with poisons – viruses and chemicals called "vaccines" – under the ruse that this slurry is harmless and will somehow keep them healthy.

The only thing to do, really, is just keep putting one foot in front of the next, being grateful for those who are waking up and supporting them. The rest, well, they may sadly have to find out what it feels like to get hit by that stray bullet.

TENNESSEE SONS OF LIBERTY

Joey Fuller, RN

Seasonal Flu and Swine Flu Vaccination Reactions

Tennessee Sons of Liberty, 4 November 2009.
https://web.archive.org/web/20091204135259/http://tnsonsofliberty.blogspot.com/2009/11/seasonal-flu-and-swine-flu-vaccination.html

As a Registered Nurse I have witnessed an increase amount of adverse reactions this season concerning the Regular Flu Vaccine and the Swine Flu Vaccine. In order to protect myself and the confidentiality of those who chose to be vaccinated, I will use the term 'patient' and not give any detailed personal information in accordance to HIPAA regulations.

The following are actual reactions to the Regular Flu and Swine Flu vaccines in Nashville, TN:

Regular Flu Vaccine- Two hours after administration, the patient had a severe burning sensation in their hands and feet, headache, and nausea/vomiting.

Regular Flu Vaccine- Numbness of the arm where the shot was administered for two days.

Regular Flu Vaccine- Increased/abnormal pain with rash at the injection site for two to three days.

Regular Flu Vaccine- Approximately two to three weeks after vaccination, the patient experienced Bell's Palsy. Bell's Palsy is a condition in which the patient experiences facial drooping/ paralysis due to malfunction/inflammation of cranial nerve VII. The patient also experienced body aches, headache, and malaise for 1-2 weeks. Bell's Palsy is idiopathic/ cryptogenic in nature, and a diagnosis is formed after ruling out other possibilities. The patient's physician stated that the Regular Flu Vaccine could have caused the Bell's Palsy.

Swine Flu Vaccine- Increased Body aches, nausea/vomiting, and headache for 2 weeks for two separate patients.

Regular Flu Vaccine- I spoke with an older African American male about his grandfather...He stated his grandfather was a perfectly healthy fellow who took no daily medicines and had no medical conditions. The grandfather took his first Seasonal Flu Vaccine at the age of 70 and died two days afterwards. This also happened to my great grandfather as explained to me by my grandmother. Both seasonal flu victims were healthy with no medical conditions, took no daily prescribed medicines, were elderly but phsycially fit and died with 2-3 days of vaccination.

Regular Flu Vaccine- Chest pain, nausea/vomiting, and severe headache was a complaint of multiple patients...occurring within 3-6 hours of administration.

SPIEGEL ONLINE

Mohrs Herzschlag

Erst die Impfung, dann das Fieber

Spiegel, 5 November 2009

https://web.archive.org/web/20100102085247/http://www.spiegel.de/panorama/gesellschaft/0,1518,659556,00.html

Die Impfung gegen die Schweinegrippe ist in aller Munde - und inzwischen in vielen Armen. SPIEGEL-ONLINE-Kolumnist Joachim Mohr hat sich impfen lassen, weil er schwer herzkrank ist und deshalb als Risikopatient gilt. Womit er nicht gerechnet hatte? Dass ihn die Nebenwirkungen so hart erwischen.

Kein Schwein soll mich anstecken, keines dieser fiesen Schweinegrippen-Viren mir etwas anhaben können. Mehrere zehntausend Menschen in Deutschland hat der globale Krankheitserreger bereits befallen - ich will nicht dazu gehören.

Was aber hilft gegen dieses Influenza-A-Virus des Subtyps H1N1? Entweder auf eine einsame Insel ziehen ohne Kontakt zu anderen Menschen (Kann ich kurzfristig leider nicht umsetzen). Hoffen, Glück zu haben (Dabei kann man schnell Pech haben). Oder sich impfen lassen - genau!

Ich gelte unbestritten als Risikopatient für die Schweinegrippe. Ich bin chronisch herzkrank, kam mit mehreren Herzfehlern zur Welt, habe mehrere operative Eingriffe an meinem Herzen hinter mir und leide bis heute an schweren Herzrhythmusstörungen.

Bei allen in den vergangenen Wochen vorgebrachten Argumenten für und gegen die Impfung schien es mir in meinem Fall äußerst sinnvoll, mich impfen zu lassen. Risikominimierung per Spritze: Viele der an der Krankheit Verstorbenen rund um die Welt waren Menschen mit schweren Grunderkrankungen, eben Risikopatienten wie ich.

Also marschiere ich zu einer der zentralen Impfstellen in Hamburg, einer Arztpraxis in der Neuen Großen Bergstraße. Eine junge, freundliche Ärztin verabreicht mit die Injektion in den linken Oberarm: Impfstoff "Pandemrix, Lot: A81CA074A".

Ich bekomme eine Impfbescheinigung und, nur für den Notfall natürlich, ein Kärtchen mit der Telefon-nummer der Arztpraxis. Was ich in diesem Moment noch nicht ahne - das Kärtchen sollte ich noch brauchen!

Schüttelfrost, Schwitzen, Fieber, unruhiger Schlaf

Geimpft werde ich am Vormittag genau um 9.45 Uhr, ich habe auf die Uhr geschaut. Das Mittagessen um 12 Uhr schmeckt mir noch, am Nachmittag fühle ich mich an meinem Schreibtisch allerdings zunehmend unwohler.

Ich denke mir aber nichts dabei.

Gegen 18.30 Uhr starte ich mit dem Fahrrad nach Hause. Die 30-minütige Fahrt, ansonsten immer eine Freude und wahrlich kein Leistungssport für mich, wird zur Qual: Jede einzelne Pedalumdrehung strengt mich an, ich kann nur in kleinem Gang fahren, zu Hause bin ich nass geschwitzt.

Vielleicht hätte ich mir diesen Spaß schenken und mir mehr Ruhe gönnen sollen?

Beim Abendbrot esse ich keinen Bissen. Ich fange an zu frieren, bekomme Gliederschmerzen. Um 21 Uhr will ich nur noch eines: schnellstens ins Bett. Ich messe Fieber und habe 38,8 Grad!

Und das ist leider kein Spaß für mich! Denn bei Fieber rastet mein Herz besonders gerne aus und startet seine irren Herzrhythmusstörungen. Fieber ist für mich eine echte Gefahr, Fieber hat mich schon wiederholt ins Krankenhaus gezwungen. Ich schlucke eine Paracetamol-Tablette, um meine Körpertemperatur zu senken - und habe Angst.

Die Nacht ist schrecklich, eine richtige Grippe-Nacht: Schüttelfrost, Schwitzen, Fieber, unruhiger Schlaf. Immer wieder quälen mich Magenkrämpfe - und Sorgen um mein Herz.

"Das müssen wir melden"

Am nächsten Morgen gegen 8.30 Uhr habe ich eine Temperatur von 38 Grad. Die Gliederschmerzen sind weniger geworden. Dafür fühle ich mich unfassbar matt, völlig zerschlagen, ohne jede Kraft. Ich kann kaum aufstehen. Ich bleibe den ganzen Tag im Bett, esse nichts, schlafe viel.

Zwischendurch rufe ich in der Impf-Praxis an. Dort nimmt eine Helferin meine Nebenwirkungen auf ("Das müssen wir melden") und bietet an, ich könne gern vorbei kommen und mit einem Arzt reden. Dazu fühle ich mich nicht in der Lage.

Bis zum Abend ist das Fieber glücklicherweise nicht mehr gestiegen, ich habe weiter 38 Grad. Ich bin unendlich erleichtert, dass mein Herz bisher durchgehalten hat, und hoffe, dass es weiter mitmacht.

Am nächsten Tag habe ich zwar keine erhöhte Temperatur mehr, bin aber immer noch viel zu schlapp, um in die Redaktion zu gehen. Immerhin schmeckt mir zu Mittag ein Teller Nudeln mit Pilzen und Karotten - langsam scheint es aufwärts zu gehen.

Die Impfung sei mit mir

Ein Drittel aller Geimpften leidet unter Nebenwirkungen, habe ich gelesen. Dazu zählen auch die, denen nur der Oberarm ein wenig brennt. Das tut meiner übrigens auch - na und?

Ich habe auch gehört, dass einzelne Menschen Fieber bekommen. Aber dass es mich derart hart erwischt, das habe ich mir nicht träumen lassen. Zumal ich mich jeden Herbst gegen die saisonale Grippe impfen lasse. Auch dieses Jahr habe ich das getan, und außer einem Pieks war nie etwas gewesen.

Ich wollte mit der Impfung gegen die Schweinegrippe meinem besonderen Risiko durch meine Herzkrankheit Rechnung tragen, habe mich jedoch durch das impfbedingte Fieber einem anderen Risiko ausgesetzt. Nun, die Medizin ist eben kompliziert. Aber eine Schweinegrippe-Erkrankung verliefe wahrscheinlich viel schwerwiegender als meine Impf-Reaktion und würde ein viel größeres Risiko bedeuten.

Drei Tage nach der Spritze fühle ich mich noch immer ziemlich schlapp, sitze aber wieder in der Redaktion. Ich hoffe, jetzt zumindest für den Winter geschützt zu sein. Die Impfung sei mit mir.

THE FLU CASE

Spiegel journalist becomes extremely ill after taking Pandemrix swine flu jab

The Flu Case, 11 November 2009, 15:07

https://web.archive.org/web/20100102040510/http://theflucase.com/index.php?option=com_content&view=article&id=1738%3Aspiegel-journalist-becomes-extremely-ill-after-taking-pandemrix-swine-flu-jab&catid=1%3Alatest-news&Itemid=64&lang=en

A journalist working for the German news magazine Der Spiegel reported that he became extremely ill with a fever of 38 degrees, chills and nausea after receiving a swine flu jab.

Joachim Mohr was injected with GlaxoSmithKline's Pandemrix, Lot: A81CA074A, in a doctor's practice in Hamburg at 9:45 in the morning.

He was a given a card with the telephone number in case of an emergency along with a confirmaiton slip when he left. By the afternoon, he started to feel ill and he barely had the strength to cycle home in the evening even though the 30 minute ride was usually a pleasure, he reports.

He arrived home drenched in sweat, had no appetite, suffered from chills and went to bed with 38 degrees fever at 9 pm. He spent a sleepless night suffering from chills, fever and stomach cramps. He stayed in bed the next day, eating little. He reported the side effects to his doctor.

Three days after the injection he was still feeling exhaustion but was able to go to work.

CTV NEWS

No serious side effects so far with H1N1 vaccine: WHO

CTV News, 5 November 2009, 6:41PM EST

https://www.ctvnews.ca/no-serious-side-effects-so-far-with-h1n1-vaccine-who-1.450932?cache=axwyxwbrej%3FclipId%3D89830

Millions of doses of H1N1 vaccine have already been administered, and so far, no unusual side-effects have been seen, reports The World Health Organization.

Dr. Keiji Fukuda, the agency's top flu expert, told a press briefing Thursday that 20 countries have started to administer the pandemic vaccine. He says the rates of reactions at the injection site, such as sore arms, are similar and maybe even lower than seen with seasonal flu shots.

"We now have good evidence, based on many people receiving the vaccines, that we have no picture of unusual side-effects emerging," Fukuda said. – "So the picture right now looks quite good in terms of the safety." He said the agency was convinced the vaccine was "highly safe."

Fukuda reiterated that WHO experts have found that the vaccine appears to provide good protection after just one dose. Even in children under 10, WHO recommends that one dose appears effective, Fukuda said.

Some countries, including the U.S., are recommending that children get two doses of the swine flu vaccine. But the U.S. is using vaccine without an adjuvant, which boosts immune response. Canada, as well as many countries in Europe, is using a vaccine with adjuvant for most of the population.

While the Public Health Agency of Canada still advises children under the age of 10 to get two half-doses of vaccine, given 21 days apart, it remains unclear whether that advice will change based on the WHO recommendations.

Fukuda said the important thing is to ensure that as many children as possible get at least one dose.

"It is better to provide one dose to as many children as possible rather than two doses to fewer children," he said.

The flu chief also noted that swine flu has now become the predominant flu strain worldwide and even appears to be starting to "crowd out" H3N2 viruses in East Asia.

And he noted that H1N1 still hasn't mutated much, an observation that has surprised many flu experts who had expected to see some change with the virus by now, given how far the strain has travelled in the last seven months.

Fukuda said H1N1 samples from around the world remain very similar to those seen when the virus was first identified in April. WHO experts do expect they will start to see some change in the strain soon, though, as immunity in the human population rises and the virus adapts.

In many countries, swine flu now accounts for up to 70 per cent of the flu viruses being sampled, Fukuda said.

Reports from across North America have suggested the virus makes up more than 90 per cent of flu viruses that have been typed.

While most people recover from the illness without needing medical treatment, Fukuda warned that the public may be concluding that this virus is insignificant. But he noted that officials are continuing to see severe cases in all age groups.

"At WHO, we remain quite concerned about the patterns we are seeing, particularly, again, because a sizable number of people do develop serious complications and death," he said. He added that cases of patients showing resistance to the antiviral drug Tamiflu remain isolated and sporadic.

"We see no evidence at all that there is widespread occurrence of antiviral resistance," Fukuda told the news conference.

THE FLU CASE

Johan Niklasson

More vaccine deaths in Sweden - desperate cover ups

The Flu Case, 7 November 2009, 08:51

https://web.archive.org/web/20100102042154/http://theflucase.com/index.php?option=com_content&view=article&id=1674%3Amore-vaccine-deaths-in-sweden-desperate-cover-ups&catid=41%3Ahighlighted-news&Itemid=105&lang=en

Five deaths within a few days from the "swine flu vaccinations" managed to slip out through the media. Authorities bragged about an "openness policy" and transparency to better calm everyone regarding the safety of the "swine flu" vaccine. But then something happened. No more official reports were made of so called side effects or deaths. Instead rumors and information about severe side effects started to spread in the Swedish society from private individuals reporting what they experienced. Blogs seem to be the people's choice when it comes to staying updated with current events nowadays.

We have reported about the five official deaths from the flu vaccine, all of them of course officially denied to have any link with the shot itself. We have received several messages and unconfirmed reports about more deaths in Sweden – all of them having one two things in common - clearly linked to the vaccine shots and not reported by media or authorities.

It has, since the media black out regarding vaccine damages in Sweden, become known that the secret contract Sweden signed with GSK who produces the poisonous Pandemrix "swine flu" vaccine used in Sweden, forbids Swedish authorities to report on any side effects until GSK themselves have analyzed the "results" and published a paper on them. (side effects are not listed in the red list)

Apparently, lower levels within the Swedish "chain of command" were "not in the need to now" and therefor proclaimed the openness policy which very quickly thereafter was completely absent and never mentioned again.

Now, Swedish citizens who wants to know about the dangers of the vaccine either have to blindly believe in the obviously fraudulent claims made by the propaganda, "the vaccine is perfectly safe" or search for stories about side effects online. All major news papers are reporting in the exact same way and use the same keywords and catch phraces - everything looking as if clearly coordinated and led by some publicity expert within a lobby group.

According to several Swedish bloggers, over twelve deaths have occurred**,** including the five official ones, but since authorities are involved with a massive cover up, we suspect many more have died from the poisonous Pandemrix "swine flu" vaccine shots.

Some smaller publications seem to be harder to monitor and control and so a local news paper called Hallands Nyheter wrote about a case on a home for elderly in Falkenberg where two of them died in the night after having received the Pandemrix "swine flu" vaccine. (deleted) The other elderly at the home and the personell thought it very strange, since the two who died where relatively healthy compared to many other who got the shot. If they were dying or very unhealthy, they would never have been vaccinated according to employees at the home.

The medical chief made a quick decision to stop the vaccination and an internal investigation was initiated. After the story was publicized locally and higher powers stepped in, the investigation "quickly concluded the deaths had nothing to do with the vaccination". Relatives to the killed ones are upset since they know there is no capacity at the home to make a proper investigation and they are upset about the cover up of the killing of their loved ones. Employees at the home were asked to keep quiet about the incident. The investigation is called a scandal.

These news and the information is not published by any larger publication in Sweden but instead by bloggers and smaller local publications. One of these have counted to at least nine dead from the poisonous Pandemrix shot. We have earlier reported about pregnant women dying from the Pandemrix shot and a pregnant woman who was hospitalized with high risk of abortion. Read this article about fears among pregnant women and especially read the comments below: many report abortions and shares how they miscarried after getting the vaccine.

It is now unclear if we ever will learn the real scope of the damages caused by the mass vaccination in Sweden. Authorities are hell bent on having as many as possible vaccinated and use every method they can part from what we might soon see - making the shots mandatory. The propaganda in Swedish media is now clearly ludicrous and very many Swedes are getting the feeling of that something very strange is going on.

I have been officially blocked from posting comments on the major Swedish web news paper Aftonbladet. Very many others report that any comment questioning the propaganda is quickly removed.

Per-Ola Ohlsson

Fick svininfluensa - trots vaccinationen

Expressen, 7 November 2009
https://web.archive.org/web/20100113101252/http://www.expressen.se/halsa/1.1771689/tva-barn-i-malmo-till-sjukhus-med-ambulans-efter-vaccineringen

MALMÖ. Två barn fördes med ambulans till sjukhus efter influensavaccineringen på en skola i Malmö. - Det har troligen samband med att de var spända inför vaccineringen, säger rektorn Gunn Hanéll.

Under dramatiska former inleddes i går vaccineringen mot svininfluensa på Djupadalsskolan i Malmö. Barnen leddes in i gymnastiksalen där vaccineringen skedde i speciella bås. En förälder berättar att madrasser lagts ut på golvet där barn som kände sig dåliga efteråt skulle kunna vila ut. - Där låg massor av barn, säger föräldern som vill vara anonym.

"Blev pigg igen"

Men det blev än mer dramatiskt när två barn blev så dåliga efter att de fått sprutan att ambulans tillkallades.

- Orsaken var inte biverkningar av vaccinet. Det ena barnet, en sexårig pojke, kände tryck över bröstet, men efter att han fått en adrenalinspruta på sjukhuset var han pigg igen, säger Gunn Hanéll.

Även det andra barnet, en pojke som går i i årskurs två, fick liknande symptom när han vaccinerades några timmar senare.

- Båda barnen är utom fara nu, säger Gunn Hanéll.

EXPRESSEN

Behrang Behdjou

Fick svininfluensa - trots vaccinationen

Expressen, 7 November 2009
https://web.archive.org/web/20100113113338/http://www.expressen.se/Nyheter/1.1771855/fick-svininfluensa-trots-vaccinationen

Helena Dahlberg Wikström från Umeå är kritisk till vaccinationsrutinerna. Själv drabbades hon av svininfluensan - trots att hon hade tagit sprutan.

- Jag har levt i falsk trygghet, säger hon till Expressen.se.

Tisdagen 27 oktober vaccinerade sig Helena Dahlberg Wikström.

Hon tillhör en av riskgrupperna, eftersom hon har diabetes, problem med njurarna och har haft hjärtinfarkter.

Vid ett besök hos sin läkare fick hon därför ta sprutan som skulle göra henne immun mot svininfluensan, berättar hon för Västerbottens-Kuriren.

På lördagen skulle Helena Dahlberg Wikström och hennes make åka till Höga kusten för att besöka svärfar.

Under eftermiddagen fick hon torrhosta, men trodde att det berodde på att hon har astma och att det var torrt i huset.

- På natten small det. Det kändes som att jag hade tusen krigare i kroppen. Det gick så fort, jag blev jättetrött och helt slut, berättar Helena Dahlberg Wikström för Expressen.se.

Klockan fem på morgonen väckte hon sin make och sa att det var dags att åka hem.

- De tog emot mig på akuten i Umeå och jag blev inlagd, säger hon.

Kritisk till hanteringen

Under de tre dagar hon tillbringade på sjukhuset fick hon ta det antivirala läkemedlet tamiflu. Nu är hon kritisk till hur sjukvården hanterar vaccinationerna.

- Efter att ha tagit sprutan levde jag i falsk trygghet. När man tänker efter så förstår man ju att vaccinet inte börjar verka på en gång, men så funderar man inte när man har fått sprutan, säger hon.

- Ingenstans har jag läst att det tar tio dagar, eller två till tre veckor, innan vaccinet börjar verka. Människor behöver veta att de fortfarande bör vara försiktiga.

Inte heller förstår hon varför folk ska stå i långa köer för att få vaccin.

- Man kan ju lika gärna bli sjuk när man sitter och väntar. På en vårdcentral måste det vara större risk att drabbas än i resten av samhället, menar hon.

- Hela vaccinationen borde ha varit organiserad på ett helt annat sätt.

Tar tid för kroppen

Nu har Helena Dahlberg Wikströms man också blivit smittad, även om det inte är bekräftat att det är svininfluensan.

- Jag mår bra nu, eller så bra som jag kan må. Det tar tid innan kroppen återhämtar sig. Nu när jag har varit och duschat känner jag att jag blir alldeles kallsvettig. Orken är inte tillbaka ännu. Hon tycker att alla ska vaccinera sig och är nöjd med den vård hon har fått.

- Men de gjorde en tabbe på sjukhuset. De skickade mig från akuten hela vägen genom sjukhuset till infektionskliniken, men det skulle det skrivas en händelserapport om.

THE FLU CASE

Swedish woman got the "swine flu" in spite of vaccination against it

The Flu Case, 7 November 2009

https://web.archive.org/web/20100102005937/http://theflucase.com/index.php?option=com_content&view=article&id=1689%3Aswedish-woman-got-the-qswine-fluq-in-spite-of-vaccination-against-it&catid=1%3Alatest-news&Itemid=64&lang=en

In an article today in Expressen a Swedish woman tells her story about how she got the "swine flu". That would have been ordinary but in her case she was vaccinated against it five days earlier. In the article it is implied that she got the flu from someone else and that her vaccination did not "take effect" for another several days.

In reality it seems to be a typical case of someone who actually got the flu from the shot. This is a well known and well documented phenomena with many types of vaccinations.

She had no symptoms for several days but the cough and in the night "it felt like I had a thousand warriors in my body". She went to the emergency reception at the local hospital and was kept there for three days. They gave her anti viral drug Tamiflu.

Now she is very critical to how authorities in Sweden have handled the information about the poisonous Pandemrix "swine flu" shot.

"- After having received the shot, I lived in a state of false security", "Nowhere did I get the information that it would take ten days or two to three weeks for the vaccine to become effective"

AFTONBLADET

Lisa Röstlund

Föll i koma av vaccinet

Aftonbladet, 8 November 2009
https://web.archive.org/web/20091111025722/https://www.aftonbladet.se/nyheter/svininfluensan/vaccinguiden/article6086396.ab

Kevin, 4 år, fick en spruta mot svininfluensan – slutade andas

I onsdags fick Kevin, 4, en spruta mot svininfluensan. Två dagar senare föll han i koma och slutade andas. – Jag var helt säker på att han var död, säger mamma Mia Brolin.

Kevin satt med sin pappa på ett kafé i Upplands Väsby centrum, norr om Stockholm. Det var fredag eftermiddag. Plötsligt började Kevin att skaka. Hans kropp böjde sig bakåt i kramper och ögonen rullade uppåt så att bara ögonvitorna syntes.

Pappan och Mia är separerade, men hon fanns i närheten och en gemensam kompis sprang och hämtade henne. ”Mia kom fort. Kevin är jättedålig.”

”Var helt vit”

Framme vid kaféet hade en folksamling samlats kring fyraåringen. – Han var helt vit om läpparna. Jag har aldrig sett en människa så vit. Jag tog upp honom i mina armar och han var helt lealös. Min enda tanke var: ”Han är död. Han lever inte mer”, säger Mia Brolin. Kevin andades inte.

Två sjuksköterskor råkade finnas på plats och instruerade henne i mun mot mun-metoden. Mia, som är höggravid, fick värkar under återupplivningsförsöken. – Jag gav honom luft medan folk omkring ringde ambulans. Jag hade ingen tidsuppfattning. Men efter ett tag kom färgen tillbaka till läpparna. Han öppnade ögonen.

Rädd för sprutor

Hemma i radhusköket sitter Mia tillsammans med sambon Dennis Karlsson, pappan till barnet i magen och extrapappa till Kevin. – Man skakar fortfarande, säger Dennis, som hann komma till köpcentret från jobbet – före ambulansen.

Under transporten till sjukhuset var Kevin mest rädd för en sak: – Mamma, jag vill inte ha en till spruta. Framme på Astrid Lindgrens barnsjukhus i Solna undersöktes han av två läkare. – De sa: ”Det här är på grund av vaccinet. Det är den enda förklaring vi kan hitta”, säger Dennis Karlsson.

Kan ha hänt tidigare

Läkarna uppgav också, enligt honom, att Kevin inte är unik: – Han är det andra fallet i dag. Det innan var också ett barn som kom in på grund av vaccinet. Professor Jan Liliemark på Läkemedelsverket kände i går inte till Kevins fall. Men han förväntar sig att få veta mer om händelsen: – Antagligen kommer en rapport om detta in till oss på måndag.

Har ni hört om något liknande fall?

– Nej. Barn kan ju hamna i koma av olika orsaker. Det kan ha samband med vaccinationen, men det kan också finnas annat som ligger bakom. Det här få man utreda.

Mia och Dennis blev övertalade av barnavårdscentralen att vaccinera Kevin.

– Vi visste inget om att något sånt här skulle kunna hända, säger Mia Brolin.

”Vill att folk ska veta”

Hon är tydlig med varför de väljer att berätta.

– Även om Kevin är ett undantagsfall så vill vi att folk ska veta att det här kan hända. Och vad hade hänt om vi hade varit hemma och han hade lekt i sitt rum och jag hade städat här nere?

Aftonbladet har inte lyckats nå ansvarig läkare vid Astrid Lindgrens barnsjukhus.

THE FLU CASE

The number of vaccine "adverse effects" in Sweden is now well over 500 ...

The Flu Case, 9 November 2009, 12:22
https://web.archive.org/web/20100102020000/http://theflucase.com/index.php?option=com_content&view=article&id=1711%3Aswedish-boy-aged-4-close-to-death-from-qswine-fluq-vaccine&catid=41%3Ahighlighted-news&Itemid=105&lang=en
https://web.archive.org/web/20100102020000/http://www.aftonbladet.se/nyheter/svininfluensan/vaccinguiden/article6086396.ab

Original article in Swedish

We have received unconfirmed reports that the number of vaccine "adverse effects" in sweden is now well over 500 including "severe adverse effects" which means life threatening conditions or death. The number of deaths is reported to us to be higher than 50 so far. This information is unconfirmed and the official numbers kept secret according to the also secret agreement between Sweden and GSK, GlaxoSmithKline who produces the poisonous Pandemrix vaccine.

I today spoke with a vaccine manufacturer (a supplier of the API, the active ingredient) at their plant here in Switzerland and they stated that they felt they had to play along in producing and supplying active ingredients to the larger "big" pharma companies since these companies are "so powerful". The person I spoke with thought it was something seriously wrong with the way the whole "swine flu" scare has unfolded and the role of WHO. The same person also acknowledged that very much research in the medical field which does not support planned products or other businesses is hidden or buried. The two people I spoke with would "absolutely not" take the "swine flu" shot. They did say that the "swine flu" meant good business.

Nine students in the US rushed to hospital after swine flu jab

The Columbus Packet, 9 November 2009.
https://web.archive.org/web/20100102055008/http://theflucase.com/index.php?option=com_content&view=article&id=1705%3Anine-students-in-the-us-rushed-to-hospital-after-swine-flu-jab&catid=1%3Alatest-news&Itemid=64&lang=en
http://myweb.cableone.net/columbuspacket/ (deleted)

Nine Lowndes County School District students were rushed to the hospital today after apparently having reactions to the H1N1 vaccine.

H1N1 shots are being made available at schools around the state by the Mississippi Department of Health. Nine students at Caledonia High School were transported to the emergency room after apparently having a reaction to the shot, said Lowndes County Superintendent Mike Halford.

"We had seven students transported by ambulance to Baptist Memorial Hospital-Golden Triangle," Halford said. "Two more students were brought in by parents or family members."

Of the nine, eight had been treated and released by 2:00 p.m. Wednesday, he said. "The H1N1 vaccine was being administered [Wednesday] at New Hope High School, New Hope Middle School and all levels at Caledonia," Halford said. "We had given the shots to the high school students, and about fifteen minutes after the shots were given we started having the issues."

Halford said that students complained of symptoms including shortness of breath, itching and hives.

"We stopped giving the shots at that time," he said.

According to Mississippi Department of Health District 6 Health Officer Rebecca James, two of the students who developed shortness of breath and hives did so because of a reaction to the shot. The others were "sympathetic reactions," she said. "There was no evidence of an allergic reaction in those six," she said. "A sympathetic reaction is also called a 'line of sight' reaction. It's similar to what happens when one person in a cafeteria throws up, and then suddenly people around them start feeling sick as well. "Hives can be a sign of a reaction to the shot, but they can also be caused by stress," she added. "Some of the hives could have been caused simply because the students were nervous about getting a shot. We may never know what caused those students to have those reactions."

Counting the two reactions at Caledonia High School today, James said that there have been a total of three allergic reactions to the vaccine around the state. "That is a very mild reaction rate," she said. "I still feel very comfortable recommending that children be vaccinated against influenza, which can be deadly. I'd rather treat hives and itching that have to treat the flu."

The vaccine that was given at Caledonia was the exact same vaccine that was given at other schools in Lowndes County, she said, and there had been no other reports of problems.

There have been 16 influenza-related deaths in Mississippi so far, she said. James said that the LCSD will continue with the H1N1 vaccinations. "Mike Halford has been very good about handling this," she said. "He intends to offer the vaccinations at the middle and elementary schools to students who want them."

A new permission form will be sent home to students before the vaccinations commence again, she said. Vaccinations at New Hope Elementary School and West Lowndes are scheduled for a later date.

[At 5:00 p.m. yesterday afternoon an ambulance was dispatched to a residence on Mike Parra Road when one of the Caledonia High students treated earlier in the day began having "seizures" and fever. Ed.]

LÆGEMIDDELSTYRELSEN
DANISH MEDICINES AGENCY

Side effects from Pandemrix® from 4 to 10 November 2009

Danish Medicines Agency, 11 November 2009.
https://web.archive.org/web/20120707051942/http://www.dkma.dk/en/topics/side-effects-and-trials/side-effects/news/side-effects-from-pandemrix-from-4-to-10--ember-2009

The Danish Medicines Agency has received the first side effect reports related to the Pandemrix® vaccine against influenza. The reports concern 13 persons that have experienced side effects from vaccination. The person vaccinated will often experience more than one side effect, and the 13 reports therefore describe a total of 34 side effects.

The side effect reports were received by the Danish Medicines Agency in the period 4 to 10 November 2009. From today, we will update the list of reported side effects on a weekly basis.

Consumption
The Danish State Serum Institute has dispensed a total of 360,000 vaccine doses, but we do not know the exact number of persons vaccinated.

Who have reported the side effects?
10 of the reports were submitted by doctors, 3 by persons that had been vaccinated.

Age distribution
One report concerns a two-year-old child, the other reports concern adults aged between 25 and 62 years. In three of the reports, the age had not been disclosed.

Gender distribution
The reports are distributed on eight women and five men.

Categorisation of side effects (adverse reactions)
The adverse reactions fall into four categories:

1. reactions at the injection site
2. allergic reactions
3. other known adverse reactions
4. unknown adverse reactions.

…

Notes on specific reports
None.

Overall evaluation
The first adverse reaction reports after vaccination with Pandemrix® in Denmark primarily describe known and expected adverse reactions that appear from the summary of product characteristics. See the factbox to the right.

General information about adverse reaction data
An adverse reaction report contained in the pharmacovigilance database does not necessarily imply that the adverse reaction is associated with the medicine (causality).

THE FLU CASE

Don't drive after swine flu jab, advises motorist organisation

The Flu Case, 11 November 2009
https://web.archive.org/web/20100102015624/http://theflucase.com/index.php?option=com_content&view=article&id=1741%3Adont-drive-after-swine-flu-jab-advises-motorist-organisation&catid=1%3Alatest-news&Itemid=64&lang=en

The motorists organisation Auto Club Europa today advised people not to drive after they take the swine flu jab because of the severity of the side effects of the shot, including head aches, muscle plain, fever and no energy.

Schweinegrippeimpfung kann Fahrtüchtigkeit beeinträchtigen

Berlin (AP) Autofahrer sollten nach einer Schweinegrippeimpfung ihren Wagen besser stehen lassen. Wie der Auto Club Europa (ACE) am Mittwoch berichtete, kann die Impfung unliebsame Nebenwirkungen auslösen und die Fahrtüchtigkeit stark beeinträchtigen. Die Symptome seien Kopf-, Gelenk -oder Muskelschmerzen sowie Mattheit und Fieber.

Auch bei einer starke Erkältung sollte besser auf das Autofahren verzichtet werden, rät der ACE. Studien hätten ergeben, dass bei erkälteten Menschen die Reaktionszeiten um bis zu elf Prozent vermindert seien. Das entspreche einem im Straßenverkehr verbotenen Alkoholpegel von 0,5 bis 0,65 Promille. - http://www.ace-online.de/

Washington Redskins Cheerleader Vaccine Victim Desiree Jennings Viciously Attacked by Medical Establishment

Hip Hop Culture Shock Shop, 11 November 2009
https://hiphopcultureshockshop.wordpress.com/2009/11/11/vaccine-victim-desiree-jennings-viciously-attacked-by-medical-establishment/

Former Redskins cheerleader Desiree Jennings, the woman who suffered a paralyzing neurological disorder after taking a flu shot, has come under ceaseless attack from the medical establishment as well as websites acting as apologists for the pharmaceutical industry, who claim that her entire illness is a hoax despite the fact that her condition has been confirmed as genuine by numerous doctors.

Jennings was a fit and healthy cheerleader up until August when she got a seasonal flu shot. Ten days after the shot she began experiencing flu like symptoms, followed by severe convulsions and black outs. After seeing around 60 doctors, Jennings was eventually diagnosed with dystonia, a paralyzing neurological disorder that causes the muscles to relentlessly contract and spasm, causing extreme difficulties with walking, talking and general body movements.

Despite the fact that doctors who vigorously examined her condition at both Fairfax Inova and Johns Hopkins confirmed that she was suffering from dystonia, and that the cause of the illness was her reaction to the flu shot, numerous apologists for big pharma have ludicrously claimed that her story is a hoax and that her disease is imaginary, citing no evidence whatsoever and having had no contact with Jennings at all.

The chief culprit in erroneously circulating rumors that Jennings' condition was a "hoax" has to be "The Inquisitr" website, a tabloid gossip rag that in-between obsessing about the vacuous activities

of Britney Spears and Lindsay Lohan, also thinks it has the knowledge to dismiss medical conditions by watching You Tube videos. On October 22, the website carried the headline, Cheerleader Flu Shot Girl: Hoax or Real? The story mentions that Jennings' condition had been diagnosed by several doctors as genuine, yet still implies that the story is a "hoax," citing no proof whatsoever. The agenda behind this becomes clear when the website lambastes "anti-vaccination nutters" for merely highlighting the case.

Not content with savaging a young woman whose life was almost destroyed just once, The Inquisitr went back for a second helping, with a story on Monday claiming that Jennings is now "cured" and that, "The chances of the whole thing being a hoax just went from about 50% to pushing towards 100%." This time around, the website didn't even bother to mention the fact that numerous doctors at major medical establishments had personally diagnosed Jennings with neurological problems, instead they claimed that Jennings had merely "told the media" that she had the disease.

In addition, the claim that Jennings is "cured" is another contrivance. The latest footage of Desiree shows her in a chair hooked up to a drip. Jennings has made progress as a result of treatment provided by doctors in LA with the aid of Generation Rescue, the charity that helped Jenny McCarthy's son recover from autism after a vaccine, but she is far from "cured".

Vaccine Victim Desiree Jennings Viciously attacked by Medical Establishment

The Flu Case // Prison Planet, 11 November 2009, 9:31

https://web.archive.org/web/20100102023651/http://theflucase.com/index.php?option=com_content&view=article&id=1751%3Adesiree-jennings-experiences-amazing-recovery-with-nature-based-therapies&catid=1%3Alatest-news&Itemid=64&lang=en

Former Redskins cheerleader Desiree Jennings, the woman who suffered a paralyzing neurological disorder after taking a flu shot, has come under ceaseless attack from the medical establishment as well as websites acting as apologists for the pharmaceutical industry, who claim that her entire illness is a hoax despite the fact that her condition has been confirmed as genuine by numerous doctors.

The inserts on flu vaccines clearly state that side-effects can include nervous system disorders, many which are treatable, but pro-vaccine cheerleaders are claiming the Jennings story is a hoax because she has made progress in recovering from her illness. The only hoax here is the one being peddled by these mouthpieces for the medical establishment, who are trying to deny the manfestly provable fact that neurological disorders are a potential side-effect of vaccines.

Jennings was a fit and healthy cheerleader up until August when she got a seasonal flu shot. Ten days after the shot she began experiencing flu like symptoms, followed by severe convulsions and black outs. After seeing around 60 doctors, Jennings was eventually diagnosed with dystonia, a paralyzing neurological disorder that causes the muscles to relentlessly contract and spasm, causing extreme difficulties with walking, talking and general body movements.

Despite the fact that doctors who vigorously examined her condition at both Fairfax Inova and Johns Hopkins confirmed that she was suffering from dystonia, and that the cause of the illness was her reaction to the flu shot, numerous apologists for big pharma have ludicrously claimed that her story is a hoax and that her disease is imaginary, citing no evidence whatsoever and having had no contact with Jennings at all.

The chief culprit in erroneously circulating rumors that Jennings' condition was a "hoax" has to be "The Inquisitr" website, a tabloid gossip rag that in-between obsessing about the vacuous activities of Britney Spears and Lindsay Lohan, also thinks it has the knowledge to dismiss medical conditions by watching You Tube videos. On October 22, the website carried the headline, Cheerleader Flu Shot Girl: Hoax or Real? The story mentions that Jennings' condition had been diagnosed by several doctors as genuine, yet still implies that the story is a "hoax," citing no proof whatsoever. The agenda behind this becomes clear when the website lambastes "anti-vaccination nutters" for merely highlighting the case.

Not content with savaging a young woman whose life was almost destroyed just once, The Inquisitr went back for a second helping, with a story on Monday claiming that Jennings is now "cured" and that, "The chances of the whole thing being a hoax just went from about 50% to pushing towards 100%." This time around, the website didn't even bother to mention the fact that numerous doctors at major medical establishments had personally diagnosed Jennings with neurological problems, instead they claimed that Jennings had merely "told the media" that she had the disease.

In addition, the claim that Jennings is "cured” is another contrivance. The latest footage of Desiree shows her in a chair hooked up to a drip. Jennings has made progress as a result of treatment provided by doctors in LA with the aid of Generation Rescue, the charity that helped Jenny McCarthy’s son recover from autism after a vaccine, but she is far from "cured”.

Blogger Mark Lorenz, writing on the Manolith website, viciously attacks Jennings for ‘faking’ her disease while again providing no proof at all that she faked it, failing to mention that doctors confirmed she had a disease, and failing to explain what possible benefit a young, healthy and happy cheerleader could get from wasting months of her life "feigning” a debilitating illness.

"But guess what? It was all fake,” he writes. "Yes, fake. All of the hemming and hawwing and talk over how vaccines are terrible and need to be tested more, mostly from the same people who say no food is safe to eat but raw food, and LOOK AT MY HYBRID CAR – their poster girl is fake. Sorry if I seem contemptuous, but I have no sympathy for people who go on national TV feigning illnesses and blaming them on a source that might actually do some good in the world.”

The aggressive zeal with which these bloggers have ceaselessly attacked a diseased young woman is stunning to behold, but they seem to be borrowing most of their cockamamie talking points from Dr. David Gorski, labeled "the bitchy diva of Scienceblogs,” by Age of Autism writer J.B. Handley.

In his article today, Handley exposes how Gorski, who has been on the warpath attempting to smear and discredit the "anti-vaccine movement,” has seized upon the Jennings story with wanton abandon in an effort to rebuild the credibility of vaccines that are being rejected in accelerating numbers across America due to concerns about side-effects and dangerous additives like mercury and squalene.

Handley chastises Gorski’s "angry, disrespectful, biting, caustic, and immature approach” in his efforts to counter the Desiree Jennings case. The main body of his article is reprinted below.

The Desiree Jennings case appears to be bringing out the absolute worst in many of the bloggers who oppose our community. As one example, I read a post by Dr. Steven Novella where he "reported” on a string of events involving Generation Rescue and the Desiree Jennings case that had no basis in reality and was simply false. We have neurologists breaking tabloid-level stories? Dr. Novella as investigative journalist? Too funny.

In no particular order, the Desiree Jennings case appears to be causing doctors to break all sorts of medical ethical boundaries including:

- Challenging Ms. Jennings’ original diagnosis of dystonia. Since when do doctors make long-distance video-only diagnoses? Don’t these doctors realize, by offering up potentially false commentary on the nature of Ms. Jennings diagnosis in a story that has captivated the world, that they will one day be called to task for such a glaring breach of medical ethics?

- Claiming Ms. Jennings condition is all in her head. For parents of children with autism, this one has a familiar ring. How on earth do Doctors like Gorski and Novella dare throw out a psychological diagnosis on a patient they have never examined? Thank God she found a doctor who knew it was all in her body.

- Claiming the flu shot couldn’t possibly cause her condition. Once again, how on earth does a long-distance doctor determine this? Vaccines cause a wide variety of side-effects, but Ms. Jennings’ condition just couldn’t be vaccine-induced? To hell with what doctors who did examine her actually determined, we are the only arbiters of truth. It’s nuts.

- Claiming she couldn’t possibly recover from a condition she didn’t even have. Forget the HBOT, chelation, B-12, vitamins, etc., Ms. Jennings couldn’t possibly recover, much like our kids never do, either.

It’s great to watch these "doctors” dig themselves into a bigger and bigger hole. I’m not sure doctors like David Gorski realizes how silly their comments look to the average American and how much they have exposed themselves as the true story of what Desiree went through emerges. Thank you, Orac, for showing the world your true colors, because the world is most certainly watching.

The desperation with which apologists for the vaccine industry have gone about trying to savage the credibility of the Desiree Jennings case illustrates how damaging the story has been to the pharmaceutical lobby and their floundering agenda to coerce as many people as possible into taking their dangerous swine flu shot.

The Jennings case, allied to the story out of Germany about how elitists were given access to a special version of the vaccine that didn’t contain additives but was not available to the general public, has undoubtedly contributed to the mass resistance to the H1N1 shot that continues to build across Europe, Canada and North America.

No amount of callous back-biting, gnashing of teeth, and contrived smear attempts on behalf of the vaccine lobby and their media apologists can now stop that momentum. The word is out – people know what’s in your vaccines and there’s no way to reverse that revelation.

In a video message, Jennings gives an update on her condition and also reveals how her MySpace and Facebook pages have been constantly hacked. Watch below.

Desiree Jennings Experiences Amazing Recovery with Nature-based Therapies

The Flu Case, Educate Yourself, 12 November 2009, 07:07
https://web.archive.org/web/20100102023651/http://theflucase.com/index.php?option=com_content&view=article&id=1751%3Adesiree-jennings-experiences-amazing-recovery-with-nature-based-therapies&catid=1%3Alatest-news&Itemid=64&lang=en
http://educate-yourself.org/vcd/desireejenningsrecovery08nov09.shtml

Desiree Jennings is the 26 year old cheerleader and marathon runner was who severely crippled with a neurological disorder diagnosed as dystonia in the wake of taking the seasonal Flu vaccine (that government officials and pharmaceutical shills keep telling us is "safe").

Don Nicoloff mentioned to me on the phone tonight that he heard an audio clip from a radio show in which Dr Rashid Buttar of Huntersville, North Carolina, the physician who helped Desiree detoxify her body of the POISONS given to her when she got vaccinated with the saving Swine flu vaccine, explain how he applied intravenous solutions including chelating agents, anti-oxidants, nutritional support, and NATURE-BASED anti-viral compounds over a period of 36 hours which resulted in a stunning and amazing turnaround for Desiree from the seizures she was experiencing nearly EVERY MINUTE, with no ability to talk, and unable to breathe for 10 or 15 second intervals when first carried into his clinic.

You can hear the entire story from Dr Buttar himself in this radio show interview with Robert Scott Bell On October 25, 2009

The interview below is a November 6, 2009 update with Robert Scott Bell on the Michael Savage radio show on Desiree's amazing recovery with a review and update from Dr Buttar on Desiree's treatment, along with comments from Desiree's husband, Brandon Jennings.
=> https://www.youtube.com/watch?v=GD1BAxVnFdc

Medical Director, Dr. Rashid A. Buttar is a graduate of the University of Osteopathic Medicine and Health Sciences, College of Medicine and Surgery. He trained in General Surgery and Emergency Medicine and served as Brigade Surgeon and Director of Emergency Medicine while serving in the U.S. Army. Dr. Buttar is board certified in Clinical Metal Toxicology, Preventive Medicine, is board eligible in Emergency Medicine and has achieved fellowship status in three separate medical societies.

Authorities dismiss connection to H1N1 vaccine precisely as they conspired to do months before

Prison Planet, 12 November 2009
https://web.archive.org/web/20091115112228/http://www.prisonplanet.com/teen-diagnosed-with-guillain-barre-syndrome-after-swine-flu-shot.html

A high school athlete from Virginia was diagnosed with Guillain-Barre syndrome hours after receiving a swine flu shot, but health authorities are attempting to dismiss the connection as a coincidence, precisely as they resolved to do long before the H1N1 vaccination program even started.

14-year-old Jordan McFarland developed severe headaches, muscle spasms and weakness in his legs following a swine flu shot. He was diagnosed by doctors at Inova Fairfax Hospital as having Guillain-Barre syndrome, the nerve disorder that was prevalent in recipients of the vaccine during the last mass swine flu vaccination program in 1976.

"Connin and Jordan's father, Calvin McFarland, both 38, believe the shot sparked the illness that came on 18 hours after the boy's vaccination," reports MSNBC.

Despite GBS's clear historical link with the swine flu shot, allied with the fact that health officials back in August warned neurologists that they needed to look out for increases in cases of the brain disorder following the launch of the immunization program, asked about the case of McFarland, the CDC's Dr. Claudia J. Vellozzi claimed that there was "no clear link between the new vaccine and the disease."

Efforts on behalf of health authorities to claim that debilitating side-effects and nerve disorders such as GBS have no connection to the vaccine, despite the fact that they are clearly listed on vaccine inserts as potential dangers, is unsurprising considering this is precisely what officials resolved to do before the swine flu mass vaccination program began.

Back In September, Reuters reported on how public health officials were expecting "an avalanche of so-called adverse event reports, which are reports of death, illness or other health trauma," in the two weeks after people receive the vaccine.

"We are going to be overwhelmed with potential events," said Mike Osterholm, a public health expert at the University of Minnesota.

Authorities therefore resolved to dismiss any connection to the swine flu shots a host of heart attacks, strokes and miscarriages that "will be blamed on the H1N1 vaccine," effectively performing a blanket diagnosis months in advance.

Earlier this month, the U.S. government appointed what the media ludicrously billed as an "independent" group of health advisors who were tasked with whitewashing adverse reactions to the swine flu vaccine and 'explaining' them to the public as mere coincidence.

The group is headed up by none other than Dr. Marie McCormick of the Harvard School of Public Health. McCormick and her affiliated organizations have routinely issued reports over the past 10

years supporting the government's position on the link between vaccines and autism, dismissing a correlation entirely despite overwhelming evidence that contradicts this notion. McCormick has been widely criticized by other health experts for her dogged denial of the link between vaccines and autism.

So far from being "independent," the group is in fact appointed by the government and lead by one of the government's chief whitewash proponents in the context of vaccine dangers and side-effects.

Pharmaceutical companies can be assured that they won't face reprisals for injuries and deaths that will inevitably occur as a result of exposing millions to mercury and squalene additives that are contained in the H1N1 shot during a mass vaccination program, because the government has already acted to provide them with blanket immunity from lawsuits.

"Vaccine makers and federal officials will be immune from lawsuits that result from any new swine flu vaccine, under a document signed by Secretary of Health and Human Services Kathleen Sebelius," reported the Associated Press back in July.

Teen Diagnosed with Guillain-Barre Syndrome after Swine Flu Shot
The Flu Case, 12 November 2009.

LÄKEMEDELSVERKET
SWEDISH MEDICAL PRODUCTS AGENCY

Summary of adverse drug reaction reports in Sweden with Pandemrix
(received up to November 10)

Läkemedelsverket, 12 November 2009
https://web.archive.org/web/20111211081808/http://www.lakemedelsverket.se/english/All-news/NYHETER---2009/Summary-of-ADR-reports-in-Sweden-with-Pandemrix-received-up-to-November-10-/

As of today, about 2.1 million doses of Pandemrix have been distributed in Sweden. In total, almost six hundred adverse drug reaction (ADR) reports have been received by the MPA from Health Care Professionals and close to 900 reports from Consumers. The ADR reporting pattern is generally consistent with the expected pattern seen previously in the clinical trials. In this compilation of ADRs reported in Sweden with Pandemrix, allergic reactions, neurological reactions and reactions in children are specifically addressed.

…

Deaths reported

A cumulative total of 8 reports of death have been received, all of which have had a temporal association with vaccination. The time between the vaccination and the death has varied between 12 hours and 4-5 days. These eight patients all had previously known chronic diseases such as cardio-vascular disease, pulmonary disease, diabetes, renal failure, dystrophic muscle disease and senile dementia. All patients were on chronic medical treatment. Autopsy results are available for four of the cases and in all these cases a relation between the vaccination and the death is considered unlikely. For the other cases there is insufficient information and autopsy protocols are lacking which limits the assessment. These reports are still under investigation and further information will be sought, but from what has emerged so far there is nothing to confirm a causal association between the vaccination and the death.

In assessing the number of reported deaths, it is - as mentioned in previous compilation - important to take into account that in Sweden on average 200-250 deaths occur per day and at present a large proportion of the population, particularly the elderly and other risk groups, are being vaccinated. The majority of deaths occurring daily in Sweden are older people with complications of chronic diseases.

La vaccination H1N1 et les médias officiels sont mal barrés avec Guillain-Barré

AGORA VOX, 13 Novembre 2009
https://mobile.agoravox.fr/tribune-libre/article/la-vaccination-h1n1-et-les-medias-64923

L'annonce n'a pas été occultée par les médias. Elle a même fait les titres. Une professionnelle de santé a été diagnostiquée comme souffrante du syndrome de Guillain-Barré. Elle avait subi il y a peu une injection du Pandemrix, qui n'est pas un filtre magique qu'utilise Astérix mais tout simplement le vaccin H1N1 produit par la firme GSK. Une nouvelle qui risque de gripper fortement la campagne de vaccination. Pour les responsables, la détection d'un cas avéré de ce syndrome, c'est un peu comme dans un village l'annonce qu'un tueur en série récemment libéré de prison, revient s'installer à 6 kilomètres du patelin. En deux mot, ce syndrome de Guillain-Barré désigne une affection neurologique affectant les fibres nerveuses périphériques par un processus d'auto-immunité, autrement dit, par l'attaque du système immunitaire de constituants faisant partie intégrante de l'organisme. Ces maladies auto-immunes sont bien connues. La maladie de Guillain-Barré se produit rarement, environ 1000 cas par an en France, suite à une infection virale ou alors à l'injection d'un vaccin anti-grippal. Dans la plupart, le syndrome est réversible et le patient récupère. Mais les statistiques affichent quelques décès.

La crainte des autorités n'est pas d'ordre sanitaire mais psychosociale. Rappelons qu'en 1976, 45 millions d'Américains furent vaccinés contre un virus grippal H1N1, identifiée dans la base militaire de Fort Dix, suite au décès d'un soldat. D'autres personnels de cette base ont été affectés par la grippe mais on ne dénombra aucun décès. Par contre, quelques centaines de syndromes Guillain-Barré furent identifiés, avec quelques décès, et sous la pression médiatique, la campagne fut stoppée. Cet épisode est comme on s'en doute rappelé dans le contexte actuel de la pandémie H1N1. Les opposants au vaccin ne se sont pas privés d'utiliser ce syndrome comme argument incitant à ne pas se faire vacciner. Le terrain immuno-médiatique était pour ainsi dire préparé. Et donc, la réaction d'hypersensibilité médiatique s'est produite. Les autorités n'avaient pas le choix. Elles étaient obligées d'annoncer un cas de Guillain-Barré, en affirmant et c'est légitime, que le lien avec la vaccination n'est pas établi. Cacher l'information eut été bien plus dommageable, car les opposants au vaccin se seraient vite dépêchés d'invoquer la thèse du «on nous cache tout».

Pour être honnête, le syndrome de Guillain-Barré n'est pas un motif sanitaire suffisant pour justifier le refus de vaccination. Mais comme on le sait depuis l'apparition de cette pandémie, la déraison se propage et c'est donc par une subtile ruse de la déraison que la campagne de vaccination vient d'être troublée. C'est pour ainsi dire, une peur contre une autre.

A cette occasion, on voit apparaître un subtil ballet médiatique traduisant et même confirmant une fracture entre d'une part le monde des gouvernances, experts, élites et médias, et d'autre part la société dite d'en bas, avec ses citoyens surfant sur le Net et refusant de se plier aux injonctions politiques et étatiques. Les cas d'école n'ont cessé de se répéter, après le précédent du TCE refusé par les Français en 2005. La loi Hadopi, l'affaire Polanski, ont récemment dévoilé cette fracture entre ceux qui dirigent le pays, avec les médias à l'appui, et ceux qu'on ne sait pas trop comment nommer, autrement dite, le peuple français ou alors la société civile.

Ce matin sur France-Inter, Jean-Marie Colombani ne s'est pas privé de fustiger ces Français qui refusent le vaccin, allant jusqu'à invoquer une régression des esprits. Il a déploré le fait que les médias ne puissent pas parler sereinement de cette campagne et de santé publique, sans qu'on les accuse de faire le jeu des politiques et des industriels. Colombani, directeur de Slate, n'a fait que reprendre les propos d'un de ses chroniqueurs, Jean-Yves Nau, par ailleurs co-auteur avec Antoine Flahault d'un livre sur la pandémie et qui sur son blog, se plait à moquer les mécréants qui, en refusant d'admettre la pandémie et l'injonction vaccinale, se comportent comme de vulgaires croyants d'avant les Lumières. Flahault s'en prend au Net, ce médias dépeint comme un caniveau par Mitterrand et considéré comme un confessionnal par cet épidémiologiste distingué qui ne se prive pas d'en appeler à Condorcet pour justifier les directives sanitaires, singeant de ce fait notre président Sarkozy se réclamant de Jaurès pour appuyer sa politique. Quant à Colombani, son attitude face à la campagne de vaccination ressemble de très près aux injonctions d'un Bernard Guetta qu'on a connu très passionné sur ces mêmes ondes à la même heure, en 2005, lorsqu'ils vociférait dans la campagne du référendum pour en appeler au bon sens des Français qui devaient suivre les élites éclairées et voter pour le traité. Du coup, les bureaux de vote étaient remplis de citoyens venus refuser le TCE, mais les centres de vaccinations ont été désertés et c'est là le signe d'une étrange comédie et d'une authentique confusion dont on ne saurait accuser les Internautes et les Français.

Ce que je peux vous dire, c'est qu'une bataille philosophique se joue avec cet événement pandémique. Qui peut se réclamer des Lumières et de la Raison ? Dans mon ouvrage, c'est la déraison du système sanitaire et des médias que je pointe, n'hésitant pas à évoquer le signe d'une époque crépusculaire sur fond de machines techniciennes obstinées dans la mise en place de solutions. On aura noté que la plupart des médias soutiennent l'action de la ministre, y compris sur Rue89 ou l'une des journalistes se félicite d'être passée par la piqûre, accomplissant de ce fait son devoir de citoyenne responsable de la santé collective. Le principal constat à retenir, c'est que cette pandémie, avec son déroulement sanitaire et médiatique, dévoile une fracture entre les élites et le peuple français. Nos médias si critiques à l'égard des Américains du temps des ADM de Saddam, ne sont guère regardant sur le manque de recul critique dont ils ont fait preuve pendant cette pandémie. La désinformation est même au rendez-vous, lorsque les quelques milliers de morts sont annoncés aux States, sans vérification de sources, assortis d'une interprétation erronée. La mortalité serait quatre fois supérieure aux prévisions statistiques. Oui, mais quelles sont ces statistiques. Tous les épidémiologistes savent que les modèles ne sont pas fiables et d'ailleurs, où sont passés les millions de morts après la pandémie annoncée de virus H5N1 ?

m&C Health

Case of crippling illness linked to swine flu vaccination in France

M & C, Health News, 13 November 2009, 8:32 GMT
https://web.archive.org/web/20091116162513/http://www.monstersandcritics.com/news/health/news/article_1513116.php/Case-of-crippling-illness-linked-to-swine-flu-vaccination-in-France

Paris - A young woman was diagnosed with a crippling illness possibly linked to the vaccine being used protect the French public against swine flu, the health ministry said late Thursday.

The woman, who was only identified as a health worker, came down with Guillain-Barre Syndrome (GBS) six days after receiving her swine flu vaccination.

GBS is a rare crippling disease that could lead to death if severe pulmonary complications and nervous system problems are present. Every year, about 1,700 cases of the disease are diagnosed in France.

Health Minister Roselyne Bachelot said the case diagnosed was light and that the woman was recovering.

However, news of the apparently vaccine-related illness is likely to dampen enthusiasm here for getting vaccinated against swine flu.

In 1976, the United States halted a vaccination programme against swine flu because some 500 inoculated people came down with GBS, with 25 of them dying. At the time, researchers concluded that the vaccine led to one additional case of GBS per 100,000 people.

The French government began its public vaccination programme Thursday, starting with persons in contact with infants; health professionals; and high-risk individuals, notably those suffering from respiratory ailments.

A poll made in October revealed that only about 17 per cent of the French planned on being vaccinated.

THE FLU CASE

Eight deaths in Sweden reported due to Swine Flu jab, admits Medical Products Agency

The Flu Case, 13 November 2009

https://web.archive.org/web/20100102010913/http://theflucase.com/index.php?option=com_content&view=article&id=1783%3Aeight-people-in-sweden-reported-to-have-died-as-a-result-of-pandemrix-admits-medical-products-agency&catid=41%3Ahighlighted-news&Itemid=105&lang=en

The Swedish government's medical products agency has said that it has received reports of 8 people dying in connection with GlaxoSmithKline's Pandemrix swine flu jab from doctors and patients so far.

There is no requirement to report deaths and side effects from the swine flu jab in Sweden even though it has not been tested. A GSK study in the UK on the side effects of the GSK jab is considered adequate for Sweden. The lack of proper monitoring has sparked fears that the 8 deaths are just the tip of the iceberg.

The Swedish medical product agency has downplayed the link between the swine flu vaccine and the deaths, saying that people who died shortly after taking the jab were seriously ill from other diseases.

However, the chronically ill were one of the vulnerable group targeted for the swine flu jab on the grounds that they would derive an especial benefit from it.

The results of only four autopsies on people who died after taking the Pandemrix jab in Sweden are known.

"Autopsy results are available for four of the cases and in all these cases a relation between the vaccination and the death is considered unlikely," writes the medical products agency.

It is not clear how many people in Sweden have taken the swine flu jab making an assessment of how risky the jab is impossible.

The Swedish government has said that 2.4 million doses have been distributed but that it has no figures on how many jabs have actually been given with some medical sources reporting that only 150,000 jabs have been administered so far in Sweden.

This is the Swedish medical product's agency report on deaths and side effects associated with the swine flu jab:

H1N1: 91 signalements d'effets indésirables sur 100.000 vaccinations

Liberation, 13 Novembre 2009, 19:07
https://web.archive.org/web/20091115151743/http://www.liberation.fr/societe/0101602828-h1n1-91-signalements-d-effets-indesirables-sur-100-000-vaccinations

Dans son bulletin de suivi de pharmacovigilance des vaccins couvrant la période 21 octobre/10 novembre, où seuls les professionnels de santé pouvaient être vaccinés, l'Afssaps compte 91 cas d'effets indésirables dont 4 graves.

Après quelque 100.000 vaccinations de personnels de santé contre la grippe H1N1, 91 cas d'effets indésirables ont été signalés dont quatre cas «graves» qui ont nécessité une hospitalisation, a indiqué vendredi l'Agence de sécurité sanitaire des produits de santé.

Dans son bulletin de suivi de pharmacovigilance des vaccins couvrant la période 21 octobre/10 novembre, où seuls les professionnels de santé pouvaient être vaccinés, l'Afssaps note que «la majorité des cas rapportés (91%) a été d'intensité bénigne à modérée.»

Tous ont reçu une injection du vaccin Pandemrix de GlaxoSmithKline, le seul actuellement disponible en France.

Quatre cas graves

Les quatre cas d'effets «graves» concernent deux affections neurologiques - dont le cas «probable» de syndrome de Guillain-Barré cité jeudi soir par le ministère-, une réaction allergique et une affection respiratoire.

Un homme de 34 ans, qui avait déjà souffert il y a 12 ans de «troubles neurologiques à type de paresthésie» avec engourdissement des membres inférieurs, a ainsi présenté des signes cliniques comparables trois jours après l'injection du vaccin. Des examens sont en cours pour établir la cause, le patient est toujours hospitalisé et son état «s'améliore».

La femme de 37 ans soupçonnée d'être atteinte de syndrome de Guillain-Barré n'avait pas d'«antécédents médicaux particuliers». Elle a présenté «des paresthésies (fourmillements, troubles de sensibilité), ascendantes des pieds jusqu'au cou et irradiant vers les membres supérieurs, 6 jours après la vaccination par Pandemrix.» «Un diagnostic de syndrome de Guillain-Barré de forme modérée est suspecté» mais des examens sont en cours pour établir la cause.

Le troisième cas est «une réaction allergique à type d'oedème de Quincke» survenue juste après la vaccination chez une femme de 26 ans «sans aucun antécédent personnel ou familial d'allergie». «Son état s'améliore sans aucune séquelle sous traitement adapté».

Enfin une femme de 30 ans, «avec des antécédents médicaux d'allergie aux poils de chat», a présenté un tableau clinique associant spasme des bronches, essoufflement, fièvre et urticaire le soir de la vaccination. (Source AFP)

THE FLU CASE

At least 91 "undesirable" side effects of Pandemrix in France

The Flu Case, 19 November 2009 10:17

https://web.archive.org/web/20100102012522/http://theflucase.com/index.php?option=com_content&view=article&id=1871%3Aat-least-91-qundesirableq-side-effects-of-pandemrix-in-france&catid=1%3Alatest-news&Itemid=64&lang=en

The French government drug regulatory agency, l'Agence de sécurité sanitaire des produits de santé, has admitted that there have been at least 91 "undesirable" side effects among people who have received the Pamdemrix swine flu jab made by GlaxoSmithKline so far.

The agency reports there were four "serious cases" reported, including a case of a woman of 37 getting the Guillian Barre Syndrome after the swine flu jab in the period between October 21st and November 10th.

However, the agency plays down the link between the swine flu jab and the disease, saying further tests are needed to establish the cause of the "suspected" case even though doctors say the 37-year-old woman has Guillian Barre Syndrome.

There appears to be requirement to report side effects of the untested swine flu jab in France and so the number of side effects caused by the swine flu jab could be far higher than the figures issued by the agency.

The agency said some 100,000 health care workers have taken the swine flu jab so far.

French Woman Gets Crippling Illness after H1N1 Vaccine

PrisonPlanet // The Flu Case, 13 November 2009, 16:44
https://web.archive.org/web/20100102040708/http://theflucase.com/index.php?option=com_content&view=article&id=1770%3Afrench-woman-gets-crippling-illness-after-h1n1-vaccine-&catid=1%3Alatest-news&Itemid=64&lang=en

A young woman in France has been diagnosed with the crippling illness Guillain-Barre Syndrome (GBS) after a swine flu shot, following reports yesterday about a Virginia teen who was similarly struck down by the disease hours after receiving the H1N1 vaccine.

The woman, identified only as a health worker, was diagnosed with GBS six days after she received the swine flu shot, according to the French health ministry.

Health Minister Roselyne Bachelot said the case diagnosed was light and that the woman was recovering. "News of the apparently vaccine-related illness is likely to dampen enthusiasm here for getting vaccinated against swine flu," reports Deutsche Presse-Agentur.

France has been at the center of a Europe-wide resistance to getting the swine flu shot, after authorities initially announced their intention to vaccinate the entire population. Outrage peaked in central Europe following the revelation that German Chancellor Angela Merkel and government ministers, as well as the armed forces there, received a special additive-free H1N1 vaccine that didn't contain ingredients such as mercury and squalene that were included in shots for the general public.

France's swine flu vaccination program has barely even begun, with so-called "high risk" individuals starting to receive the vaccine from yesterday. Reports of side-effects this early will do nothing to change the minds of 83 per cent of the French public, who indicated in a Le Monde survey they they would not take the vaccine.

55 per cent indicated they would take the shot in September, but that number has now plunged to just 17 per cent, figures partly influenced by media attention on the case of nine individuals who have filed formal charges in the French courts claiming that the H1N1 mass vaccination campaign is a deliberate attempt to poison the French population.

The drop in numbers willing to take the vaccine mirrors that in Germany where just 13% now say they are willing to take the shot, down from 51% in July.

Similar resistance to taking the vaccine is widespread throughout the continent, from Scandanavia to Bulgaria to the Netherlands, there is barely a country in Europe where a majority of the population have indicated they will take the vaccine and in most countries the vast majority have indicated that they will not get inoculated due to fears of side-effects.

As we reported yesterday, a high school athlete from Virginia was diagnosed with Guillain-Barre syndrome hours after receiving a swine flu shot, but health authorities are attempting to dismiss the connection as a coincidence, precisely as they resolved to do long before the H1N1 vaccination program even started.

Despite GBS's clear historical link with the swine flu shot after more got ill from the vaccine than got swine flu during the 1976 mass vaccination program,, allied with the fact that health officials back in August warned neurologists that they needed to look out for increases in cases of the brain disorder following the launch of the immunization program, asked about the case of McFarland, the CDC's Dr. Claudia J. Vellozzi claimed that there was "no clear link between the new vaccine and the disease."

Efforts on behalf of health authorities to claim that debilitating side-effects and nerve disorders such as GBS have no connection to the vaccine, despite the fact that they are clearly listed on vaccine inserts as potential dangers, is unsurprising considering this is precisely what officials resolved to do before the swine flu mass vaccination program began.

Back In September, Reuters reported on how public health officials were expecting "an avalanche of so-called adverse event reports, which are reports of death, illness or other health trauma," in the two weeks after people receive the vaccine.

Authorities therefore resolved to dismiss any connection to the swine flu shots a host of heart attacks, strokes and miscarriages that "will be blamed on the H1N1 vaccine," effectively performing a blanket diagnosis months in advance.

Earlier this month, the U.S. government appointed what the media ludicrously billed as an "independent" group of health advisors who were tasked with whitewashing adverse reactions to the swine flu vaccine and 'explaining' them to the public as mere coincidence.

The group is headed up by none other than Dr. Marie McCormick of the Harvard School of Public Health. McCormick and her affiliated organizations have routinely issued reports over the past 10 years supporting the government's position on the link between vaccines and autism, dismissing a correlation entirely despite overwhelming evidence that contradicts this notion. McCormick has been widely criticized by other health experts for her dogged denial of the link between vaccines and autism.

Vaccine Victims Blamed for National Emergency: Humanicide and What's Next

Prevent Disease, 13 November 2009
https://web.archive.org/web/20100102095323/http://preventdisease.com/news/09/111309_vaccine_victims_blamed_emergency.shtml

In Salem, Massachusetts, in 1692, medical doctors failed to determine the cause of bizarre behavior among youngsters in that town. Religious zealots, steeped in their cult, diagnosed satanic possession to justify criminal prosecutions and serial slayings.

The publication of "Why you can't get swine-flu vaccine" in Rupert Murdoch's New York Post (Nov. 3, 2009) by Robert Goldberg, Vice President of the Center for Medicine in the Public Interest, proves how human intelligence has devolved since Salem's victims were blamed to popularize status quo psychopathology, social injustice, and mass murder otherwise called institutionalized genocide.

According to Goldberg, partnered with Peter Pitts, mainstream media's health pundits for consumer protection, the H1N1 National Emergency declared by Barack Obama is due to fringe lunatics who think mercury is harmful when injected by vaccines; not "vaccine shortages".

Goldberg blames people like me for heralding mercury toxicity's links to neuro-developmental and behavioral disorders in children (e.g., autism). We are blamed for allegedly pressuring governors into ordering single versus multi-dose vials (as if the government of the US has ever listened to vaccine prohibitionists). The different vials have differing mercury concentrations (which indicts lacking industry standardization of heavy metal toxic mercury levels evidencing gross criminal negligence rationalized by pseudoscience) and the single dose vials are more costly and time-consuming to produce. Thus, we victims of mercury intoxication and vaccine injuries are blamed for the alleged vaccine shortage and national Model State Emergency Health Powers Act implementation advancing across the country.

They are Killing Us

I suffer from eczema--a common condition linked by science to vaccine mercury and/or injected foreign proteins causing multiple chemical sensitivities and autoimmune conditions. Vaccine-linked eczema now curses between 10-15 percent of the American people. Eczema is most often caused by vaccination intoxication. Human bodies are injected with mercury and foreign proteins that attach to normal body parts. The combination of mismatched protein parts forms an "antigenic complex" that is attacked by white blood cell bodyguards. This results in the vast majority of autoimmune diseases, including eczema. Such diseases profit petrochemical-pharmaceutical industrialists.*

My mother died of Guillain-Barre Syndrome (GBS) from the 1976 Swine Flu Vaccine campaign. My sister-in-law was crippled with rheumatoid arthritis (RA) from a hepatitis B vaccine. My brother-in-law receives Canadian military compensation for a vaccine injury called multiple sclerosis (MS). My best friend has type-1 diabetes thanks to a flu shot. These illnesses are all autoimmune diseases proven in science to be linked to, or caused by, vaccinations.**

I testified briefly before the US Congress on vaccine mercury's link to autism. I personally witnessed legislative officials' gross criminal neglect of the scientific study commissioned by the US Centers for Disease Control (CDC) by Verstraeten, et. al, titled, "Thimerosal VSD Study: Phase I-- Update 2/29/00." Herein, definitive links between vaccine mercury intoxication and neuro-developmental and behavioral disorders in children were reported. This report was originally censored, then modified, for subsequent official publications eliminating all findings condemning vaccine mercury, thus keeping autism a "medical mystery."

Today, everyone practicing any form of natural medicine is endangered. Energy medicine is particularly suppressed along with paradigm-shifting biophysics, hydrosonics, and electrogenetics that could eliminate all reliance on drug industrialists. Practitioners in these fields are persecuted for truth-telling about vaccine illnesses and deaths linked to mercury poisoning and antigenic complexes.**

History Repeating

Medical industry censorship and persecution is reminiscent of the mysterious Salem witch trials. Historians speculate a combination of events, including an untimely smallpox outbreak, created the climate for this public fright. One-hundred and forty people were accused of witchcraft. Forty-three people were supposedly afflicted. Nineteen people were hanged, one person was pressed to death, thirteen people died in prison, and as many as 1200 persons were victimized in other ways.

What terminated this deadly madness is the same reason Rupert Murdoch's yellow press, the New York Post, published Robert Goldberg's diatribe. Public support and false belief in the "witches" began to wane; as is happening now with growing distrust of vaccines and fraudulent vaccine trials. The "silent majority" sees through transparent safety assurances and government intrusions into our lives. People are frightened and fed-up with deadly disasters like the Merck company's VIOXX and 1976 Swine Flu vaccine fraud, both certified by the US Federal Government.

Respected Salem ministers started to believe that some innocent people were being accused and executed for witchcraft primarily on unreliable spectral evidence (such as Goldberg presents). Today, confessions by doctors and scientists who once worked for drug giants are truth-telling, whistle-blowing, and discrediting the vaccine makers and their safety assurances over the Internet.

As the Reverend Increase Mather stated, "It were better than ten suspected witches should escape than one innocent person should be condemned." I say, "it is better that ten vaccine-prohibitionists be condemned by medical madmen than one innocent child suffer neuro-degeneration from vaccine mercury intoxication."

The Salem Witch Trials website explained, "As the accusations mounted, persons from all walks of life--rich and poor, beggar and merchant--were being accused. Additionally, the accused that originally confessed to witchcraft requested to recant their former confessions. With public confidence in the trials slipping, the cries of the afflicted were steadily ignored, and the accusations eventually stopped."

So increasingly ridiculous accusations from the status quo, such as Goldberg's, are disbelieved by increasing numbers of vaccine victims. The majority of people now see through BigPharma's fear-inflicting propaganda, exemplified by Murdoch's articles, wherein "We the People" are accused of madness, ignorance, and now allegedly causing a national emergency.

Public confidence in medicine is at an all-time low following the medically-assisted demise of our parents, friends, and siblings. The leading cause of death today is drug-induced illnesses; and these shocking statistics omit all vaccine injuries since officials criminally neglect surveying and reporting the sick and dying who's only mistake was their misplaced faith in drugs and medical deities.

It is said that medicine has extended longevity, but degenerated quality of life making death seem more appealing than drug additions and lethal side effects for millions.

Murdoch's Media-Driven Humanicide

For those who don't know, Rupert Murdoch controls the majority of American news media.

Recently, investigative journalist Sherri Kane and I exposed gross conflicting interests between Rupert Murdoch and the global drug cartel. Pregnant women were tested for H1N1 vaccine side effects using a bogus study design at Elizabeth Murdoch's Royal Women's Hospital in Australia. Rupert's daughter-in-law, Susan, oversees the Murdoch Children's Research Institute (MCRI) wherein infants and children were tested with H1N1 vaccines by Merck's subsidiary, CSL, Inc. James Murdoch, heir-apparent to Rupert's estate, oversees the Board of Directors of Glaxo-SmithKlein, another H1N1 Swine Flu vaccine maker. All of the above Murdoch affiliates administered fraudulent H1N1 vaccine studies that neglected placebo control groups and long-term surveillance to fraudulently erase statistically significant risks and provable "adverse events."

Rupert Murdoch is Co-Chairman of the David Rockefeller founded, Royal family of England chartered, Partnership for New York City (PFNYC). This is the world's most powerful biotechnology trust – the heart of the vaccine industry, "genetopharmaceuticals," and mass-media mind controlling social engineering. This is the heart of the American Medical CULTure. Their prostitutes promote and prey on people's fear, magnify microbial menaces, and persecute natural healers and alternative care providers as though they were witches practicing witchcraft.

David Rockefeller also directs the wealthy powerful Council on Foreign Relations (CFR). He co-founded, with The Rockefeller Brothers Fund, the influential Population Council. The former is the most powerful US Government think tank and policy director. The later is the world's most active depopulation organization funded by the US Government and Rockefeller-related foundations and institutions. The Population Council's goal is to reduce populations by nearly two-thirds through intoxicating drugs and vaccines, including those that cause sterility. They advocate the 1977 book, Ecoscience, co-authored by Obama administration science czar, John Holdren, calling for massive global depopulation using vaccinations for sterilization.

Evidencing this group's power, on October 16, 2009, a special gathering of CFR joined vaccine specialists and social engineers led by health media propagandist, Laurie Garrett, discussed the urgency of the vast majority rejecting vaccinations for H1N1. They articulated the need to use "shortage marketing" (i.e., fraudulently claiming vaccine shortages) to promote better public acceptance of the distrusted vaccines. Prior to this meeting, the nation's vaccine supplies were reported ample. After this meeting the media began administering shortage marketing, and hypnotizing the panicked public who lined up for their shots.

Another example official malfeasance at the highest levels of government involves the PFNYC Co-Chair, Lloyd Blankfein, the Chairman and CEO of Goldman Sachs & Co., whose manager of private client services, Linda Daines, is wife of New York State Health Commissioner, Richard Daines. The Daines's profit from vaccine sales to New York State (legally another member of PFNYC) and other governments, including the US Federal Government (officially another member of PFNYC) that stockpiles the H1N1 Swine Flu vaccine. Goldman Sachs, directed by Blankfein, was the largest shareholder in a deal they brokered in 2007 for the $15 billion sale of vaccine giant MedImmune that produces AstraZeneca's H1N1 "Flumist."

What's Next? The Expected Created "Big One?"

Flumist is the H1N1 nasal spray vaccine. People taking it spread the "live" "active" laboratory-engineered unstable virus for up to 3 weeks, putting non-vaccinated persons at risk of infection and worse. These "shed" unstable viruses more readily recombine with other circulating viruses; thus, potentially more severe outbreaks and far more deadly pandemics are now expected.

One such threat, a possible H1N1 hemorrhagic pneumonia recombinant, has emerged in the Ukraine, where the Chernobyl disaster occurred. The NATO superpower has fully engaged biological and chemical weapons research and development. This country was predicted to host a biological weapons release associated with H1N1 vaccines courtesy of the Baxter Corp around the time this outbreak occurred. Joseph Moshe, an Israeli Mossad agent, made this prediction on August 11, 2009, and his persecution and arrest made the national news.

Moshe attempted to warn US federal investigators and law enforcers about Baxter releasing a bioweapon as they had earlier this year "accidentally" shipping H5N1-contaminted seasonal flu vaccines to labs across Europe. Baxter previously shipped AIDS around the world in their HIV-contaminated blood product, heparin. This H1N1 vaccine supplier is among the least trustworthy companies in the world. Their adjuvanted vaccines are currently banned in the United States due to US Congressional condemnation, but favored by European nations. So much for consistency in vaccine science!

Here is the biggest problem. Unvaccinated persons are being vicariously "immunized" by simply going to school or work, contacting shedding H1N1 vaccinated carriers. Since more deadly viruses circulate in people, birds, animals, and the global environment, worse pandemics are predicted. Simply one "Typhoid Mary" transmitting an H1N1-H5N1 recombinant might depopulate millions of people in many nations thanks to the H1N1 vaccinations! This is what experts and officials, in fact, expect

to happen. It is the real grossly-neglected reason for the declaration of "National Emergency" by President Obama who, by the way, advanced the 2005 Senate bill to fund development of the H5N1 avian flu vaccine!

Murdoch and Blankfein's allied news sorcerer is Thomas H. Glocer, the Editor-in-Chief of Reuters News Service, who is also a member of the PFNYC. His directorship of Merck & Co, the world's largest vaccine maker, is another gross conflict of interest. Reuter's and Murdoch's News Corp. controls virtually all Western World propaganda, including the Associated Press which Murdoch directs as a board member. Murdoch and Glocer's media co-broke the story of Obama's H1N1 National Emergency declaration. Glocer broke the H1N1 Mexican Swine Flu news.

Let us not forget the conflicting interests of PFNYC member Mortimer Zuckerman, Editor-in-Chief of US News & World Report and the New York Daily News, who financed the American Lyme Disease Foundation that heavily promoted SmithKlein's disastrous Lymerix vaccine that tragically caused hundreds-of-thousands of casualties before the FDA suspended its use.

All the above are advancing massive media deception and human intoxication for population reduction through H1N1 recombinations spread by vaccinations, shedding, and reassorting with circulating viruses including, we now expect, hemorrhagic pneumonia from the Ukraine.

Concerned intelligent activists are demonized as "witches," holistic physicians are ostracized for practicing "witchcraft," and natural cures and immune boosters such as the **silver hydrosols** that could put Big Pharma out of business, are suppressed by officials of a murderous medical cult. Together, medical maniacs allied with media moguls have sewn the seeds for population reduction consistent with Population Counsel objectives and their own demise as humanity awakens to the catastrophe of this unfolding humanicide.

Dr. Leonard G. Horowitz is an award-winning author of 16 books and a Harvard-trained internationally recognized expert in public health and consumer protection. He views vaccinations as genocidal weapons for human intoxication and mass depopulation, and condemns gross criminal negligence and official malfeasance in the administration of the H1N1 Swine Flu "Scam." Go to FLUscam.com for more writings by Dr. Horowitz.

The original article by Goldberg is published here**.**

*The two most deadly myths in medical history is that: 1) vaccines, not mainly improvements in hygiene and nutrition, terminated polio and smallpox; and 2) vaccines are "safe and effective" when more than 90 percent of vaccine injuries and fatalities are criminally neglected, not surveyed nor reported.

**According to ScienceDaily.com: Approximately 75 percent of autoimmune diseases occur in women, most frequently during the childbearing years. These diseases also comprise a significant portion of chronic childhood disorders. Autoimmune disease refers to a group of more than 80 serious, chronic illnesses including diseases of the nervous, gastrointestinal, and endocrine systems as well as skin and other connective tissues, eyes, blood, and blood vessel. In all of these diseases, the underlying problem is similar--the body's immune system (including B and/or T immune cells) becomes misdirected, attacking the very organs it was designed to protect.

(http://www.sciencedaily.com/releases/2007/04/070403161855.htm)

Author's footnote: It is grossly idiotic and genocidal to neglect the diagnosis of general systemic vaccination intoxication then conjure up misdiagnoses requiring drug treatments. The best treatment, and public health measure, would obviously be to cease vaccinating and intoxicating people. Proof of this is adequately evidenced by the huge percentage of people with autoimmune diseases that even vaccine makers' package inserts warn about, eczema being a most prevalent one. This ignorance and neglect of what is obvious places the medical paradigm in jeopardy of crumbling due to iatrogenocidal stupidity.

THE FLU CASE

Child of two and woman of 18 die after getting swine flu shot in Finland

The Flu Case, 13 November 2009, 16:52

https://web.archive.org/web/20100102040548/http://theflucase.com/index.php?option=com_content&view=article&id=1772%3Achild-of-two-and-woman-of-18-die-after-getting-swine-flu-shot-in-finland&catid=41%3Ahighlighted-news&Itemid=105&lang=en

At least two people have died in Finland after getting the swine flu jab. A two-year-old child died one week after getting the shot. According to the local media, the shot "came too late and couldn't save the child."

In addition, an 18-year-woman died in the Päijät-Häme Hospital District in Lahti one week after getting the jab, according to the newspaper Helsingin Sanomat, which, however, attributes the death to the swine flu virus and not the vaccine.

In an interview with Helsingin Sanomat President Tarja Halonen said that she has not been vaccinated yet, as she does not belong to any of the risk groups, and does not plan to jump the queue.

However, the Speaker of Parliament Sauli Niinistö said the President and the government ministers should be allowed to jump the queue to get their H1N1 shots.

...

The Päijät-Häme Hospital District confirmed on Wednesday that an 18-year-old woman had died as a result of a H1N1 virus infection. She had a difficult long-term illness.

She had been admitted to the Päijät Häme Central Hospital in Lahti early on Tuesday morning. The woman had exhibited swine flu symptoms for several days, and was tested positive for the H1N1 virus.

After being treated with antibiotics and antiviral medicines, the woman was transferred to a life support machine. She died at the hospital on Tuesday night.

According to the hospital district, the patient had been vaccinated last week, but it did not manage to boost her immunity against the virus immediately.

The vaccine will offer protection against the H1N1 influenza infection in two to three weeks from the vaccination.

According to THL it is not possible to contract the swine flu from the vaccine.

The current number of H1N1-related deaths in Finland is six.

However, the number of infected individuals is tens of thousands, maybe more than 100,000. Some people get only a very mild infection, occasionally even without any symptoms.

WELT

Wuppertaler stirbt nach Schweinegrippe-Impfung

WELT, 13 November 2009
https://www.welt.de/wissenschaft/schweinegrippe/article5200078/Wuppertaler-stirbt-nach-Schweinegrippe-Impfung.html

Ein 46-jähriger Mann aus Wuppertal ist einen Tag nach seiner Schweinegrippe-Impfung aus bisher ungeklärten Ursachen gestorben. Der Mann wurde tot von einem Kollegen gefunden. Die Behörden ordneten die Obduktion an, um zu prüfen, ob der Mann allergisch auf den Impfstoff reagiert hatte.

Die Behörden in Nordrhein-Westfalen lassen den Tod eines 46-jährigen Wuppertalers untersuchen, der einen Tag nach der Schweinegrippe-Impfung gestorben ist. "Wir haben eine Obduktion angeordnet", zitierte die Nachrichtenagentur dpa den Sprecher der Wuppertaler Staatsanwaltschaft, Wolf-Tilmann Baumert. Laut Informationen der "Westdeutschen Zeitung" wurde der Mann einen Tag nach seiner Grippe-Impfung mittags tot von einem Arbeitskollegen gefunden.

Nun soll geprüft werden, ob ein Zusammenhang zur Impfung besteht. So werde geprüft, ob der Wuppertaler möglicherweise allergisch auf die Impfung reagiert hat. Auf dem Fragebogen zur Grippe-Impfung hatte er selbst eine Allergie-Anfälligkeit verneint.

Wie "Bild" berichtet, sei auch eine 65-jährige Thüringerin kurz nach der H1N1-Immunisierung gestorben. Ob es zwischen der Impfung und dem Tod der Frau einen ursächlichen Zusammenhang gibt, müsse aber auch in diesem Fall noch geklärt werden. Außerdem habe in Düsseldorf ein 30-jähriger Mann nach der Impfung einen lebensbedrohlichen anaphylaktischen Schock erlitten. Der Mann habe sich aber zu diesem Zeitpunkt noch in der Arztpraxis befunden und konnte sofort behandelt werden.

Ein internationales Forscherteam hatte bereits Ende Oktober mit Blick auf die Impfung gemahnt, dass unerklärliche schwere Erkrankungen und Todesfälle in einer ausreichend großen Bevölkerungsgruppe immer wieder vorkommen. Das gelte auch für Geimpfte, ohne dass der Impfstoff damit irgendetwas zu tun haben müsse. Unter zehn Millionen geimpften Menschen seien schon rein statistisch sechs plötzliche unerklärliche Todesfälle innerhalb von sechs Wochen zu erwarten, die nichts mit der Impfung zu tun haben, erläuterte Steven Black im Fachjournal "The Lancet".

Schweden, das bereits seit Mitte Oktober gegen die Schweinegrippe impft hat fünf Todesfälle im zeitlichen Zusammenhang mit der Spritze gemeldet. Ein ursächlicher Zusammenhang wurde bislang nicht festgestellt, betonte das Paul-Ehrlich-Institut, das die Daten vorstellte. Alle fünf Patienten hatten laut Institut chronische Erkrankungen. Die Ereignisse müssten vor dem Hintergrund von 200 bis 250 Todesfällen pro Tag in Schweden gesehen werden, wobei die Mehrheit der Fälle ältere Menschen mit chronischen Grunderkrankungen betrifft, also die Gruppe, die derzeit bevorzugt geimpft wird.

THE FLU CASE

Two Germans died after taking swine flu jab: state prosecutor to investigate

The Flu Case, 13 November 2009, 16:45
https://web.archive.org/web/20100102030320/http://theflucase.com/index.php?option=com_content&view=article&id=1771%3Atwo-germans-died-after-taking-swine-flu-jab&catid=41%3Ahighlighted-news&Itemid=105&lang=en

A 46-year-old man in Wuppertal, Germany, has died one day after receiving the swine flu jab. The man was found dead at midday by his co-workers. The state proseuctor for Wuppertal has ordered an autopsy to be performed, according to a report in Die Welt.

In addition, the Geman newspaper Bild has reported that a 65-year-old woman died in Thuringia following a jab.

In Sweden, at least 8 people have died from the jab.

According to sources, as few as 150,000 jabs have been given to people in Sweden.

The Swedish government does not have a system in place to count the number of swine flu jabs administered but only the number of doses distributed with 2.4 million so far.

Two die in China after H1N1 flu vaccine

Asia Pacific News, 14 November 2009, 11:28 hrs

https://web.archive.org/web/20091117045227/http://www.channelnewsasia.com/stories/afp_asiapacific/view/1018187/1/.html

Beijing: Two people died after they were inoculated with the H1N1 flu vaccine in China, health authorities reported, amid wariness among the Chinese about the quality of the shot.

Deng Haihua, spokesman for the health ministry, said in a statement posted on the website late Friday that authorities had been notified of the deaths in the past two days, but he gave no personal details of the victims.

Preliminary results of an autopsy on one of the victims revealed the patient suffered a sudden death due to heart issues and experts had ruled out a link to an allergic reaction to the vaccine, according to the statement.

Deng said final results had yet to be announced, and an autopsy on the second victim was underway.

But he sought to play down the news amid public concern - a survey published by state media in October revealed that over half of Chinese did not plan to be vaccinated as they were unsure about the safety of the shot.

"Specialists say that it is unavoidable that several serious adverse reactions will happen amid the more than 10 million people who have received the vaccine, and the 20, 30, 150 million who will in the future," Deng said.

China has so far reported 43 deaths from A(H1N1) influenza and more than 65,900 cases of the disease, according to the health ministry.

Two people die in China after taking the swine flu jab

The Flu Case, 14 November 2009 12:20
http://www.chinadaily.com.cn/world/2009-11/14/content_8970531.htm

Two die after H1N1 vaccination

Two persons are reported to have died after taking the A/H1N1 vaccination as the Chinese mainland prepares to vaccinate 65 million people, or 5 percent of its population, by the end of the year, health officials said on Friday.

A secondary school teacher in Hunan province died while playing basketball 8 hours after taking the jab, the provincial health department said on Friday afternoon.

But his death, according to preliminary findings, was not linked to the vaccine and it would not affect the ongoing H1N1 vaccination program, said Deng Haihua, spokesman for the Ministry of Health.

Deng did not give the details of the other victim. According to regulations, the local health authority where such deaths occur should be the one to announce it, he said.

So far, 15 people have suffered severe side effects including anaphylactic shocks (sudden drop in blood pressure or difficulty in breathing) after taking the jab, said Liu Dawei, a vaccination expert with the Chinese Center for Disease Control and Prevention.

"These people will get free treatment and cash compensation," Liu said.

Till Thursday, more than 12 million people had been vaccinated against the H1N1 flu virus, with 1,235 complaining of side effects, the Ministry of Health said. Most of the reactions, however, have been mild and temporary.

Preliminary results of the Hunan victim's autopsy show he could have died after suffering a sudden cardiac arrest, which experts say kills more than 1,700 people in the country each day.

"The Hunan teacher's death is a coincidental medical incident," Liu said.

The exact cause of his death can be known only after all his medical records, including the final autopsy report, are studied, Deng said. But the batch of vaccines from which he got the jab has been withdrawn as a precautionary measure.

The autopsy on the other victim was likely to be performed on Friday night, Deng said.

No vaccine is risk-free, but the influenza vaccine is among the safest, said Vivian Tan, press officer of the World Health Organization's Beijing office.

"We have observed minor side effects like sore arm, red rashes, low fever and headache among the people who have taken the jab. Severe side effects are very uncommon. But it's important to monitor the situation closely," Tan said.

China investigates 2 deaths after flu vaccinations

Associated Press, 14 November 2009
https://web.archive.org/web/20091118234243/http://www.google.com/hostednews/ap/article/ALeqM5hUCrj6qBD1IyWXrdfi7h1MKrcawQD9BV26C04

Beijing – Two people in China who received swine flu vaccinations died in the past week but at least one death appears unrelated to the vaccine and the other was being investigated.

The country's health ministry reported the deaths late Friday on its Web site – the first time China has announced deaths with potential links to the Chinese-made swine flu vaccine.

An autopsy showed one victim suffered a heart attack and, "experts have basically ruled out the possibility that the patient's sudden death was the result of immediate allergic reactions to the flu vaccines," the ministry statement said.

Experts were waiting for more lab results, it added.

An autopsy on the second person was scheduled for late Friday, but no results had been reported Saturday morning.

The statement gave no details on the two people, and phone calls to China's health ministry went unanswered Saturday.

The Hunan provincial health department in southern China posted a statement on its Web site Friday saying a teacher died Monday while playing basketball, eight hours after being vaccinated.

A spokeswoman for the World Health Organization office in China said the second death was a man from Tianjin, southeast of Beijing.

"Our assessment of the safety of the Chinese vaccine hasn't changed," said spokeswoman Vivian Tan. "The deaths are unfortunate, but we need to get to the bottom of it."

The health ministry has said more than 13 million Chinese have received the swine flu vaccine.

"So far from the sheer numbers vaccinated, there's a very small number of mild and ever smaller number of serious reactions. We still believe it is generally safe and effective," Tan said.

The health ministry statement said 1,235 people had been suspected of having abnormal reactions to the vaccine as of Wednesday. Reactions included fever and swelling.

Fifteen people had relatively serious responses such as anaphylactic shock, a severe allergic reaction that can be deadly.

The health ministry statement said the vaccines are generally safe and vaccinations will continue.

As of Friday, China reported about 66,000 cases of swine flu, including 43 deaths.

China Investigates Deaths after Swine Flu shot

Time CNN, 15 November 2009.
https://web.archive.org/web/20091118143417/http://www.time.com/time/health/article/0,8599,1939575,00.html

Chinese health officials reported on Nov. 13 the first deaths in people who received the H1N1 vaccine. The Ministry of Health announced that the two people, including a teacher from Hunan province, died hours after receiving their inoculations. Since September, when the ministry began its H1N1 immunization program, 12 million Chinese have received the pandemic flu shot.

A preliminary autopsy revealed that the teacher died of an apparent heart attack while playing basketball, and a ministry spokesperson told the *China Daily* newspaper that the death was a "coincidental medical incident" and not related to the vaccine. No details on the second victim have been released thus far.

As they conduct an autopsy investigation into the second death, Chinese health officials have pulled all vaccines that were manufactured in the same batch used to inoculate the teacher. Although the H1N1 vaccine has been rigorously tested and vetted for safety, no inoculation can be considered 100% safe, and some may cause adverse events, including death, in some people.

Taking an aggressive approach to the pandemic flu, the Chinese government in June asked 11 biotech companies to develop a pandemic H1N1 vaccine. Beijing-based Sinovac succeeded in developing the world's first approved swine flu shot. The company raced to conduct clinical trials and was the first to report that a single dose of vaccine, instead of the two doses that most flu experts believed would be necessary, was sufficient to protect against 2009 H1N1. In early September, China became the first country to begin swine flu inoculations.

But by the end of October, 54% of Chinese residents reported in a *China Daily* survey that they would not get the H1N1 vaccine because of concerns about the shot's safety. That prompted the director of the World Health Organization's Beijing office, Dr. Michael O'Leary, to tell the newspaper, "The H1N1 vaccine is one of the safest vaccines being used. When it's available to me, I would not hesitate to get the vaccine developed and produced by China."

Three vaccine manufacturers in China, including Sinovac, have received orders from the government for more than 34 million doses. Among the 12 million people inoculated so far, 1,235 have complained of side effects, ranging from sore arms, rashes and headaches to anaphylactic shock and sudden drops in blood pressure.

While the Chinese government has been criticized for its draconian public-health response to swine flu – using quarantines, canceling school and detaining entire planeloads of people when a single passenger appears to have flulike symptoms – the country's officials say the strict measures helped stem the spread of flu. So far, China reports about 36 deaths and 62,800 H1N1 cases – compared with U.S. government estimates of 4,000 American deaths and 22 million infections. China plans to immunize 65 million citizens, or 5% of the country's population, by the end of the year. As in the U.S., health officials are targeting high-priority groups first, including the military, police, health care workers, teachers, students and those with chronic diseases.

Two die after getting Chinese H1N1 vaccine

The Daily Pioneer, 15 November 2009
https://web.archive.org/web/20091118081925/http://www.dailypioneer.com/215922/Two-die-after-getting-Chinese-H1N1-vaccine.html

PTI | Beijing, Two people have died in China after receiving domestically manufactured vaccines against swine flu, Government said on Saturday.

The preliminary autopsy report of one of the deceased showed that the patient suffered a sudden cardiac death while results of the autopsy on the second person are still awaited, the Ministry of Health was quoted as saying by the Xinhua news agency.

"Experts have basically ruled out the possibility that the patient's sudden death was the result of immediate allergic reactions to the flu vaccines," a statement on Ministry's Website said.

Around 43 people have so far succumbed to swine flu in China due to the disease.

DIGITAL JOURNAL

Two die in China after H1N1 Swine Flu vaccination

Digital Journal, 15 November 2009
https://web.archive.org/web/20091119025123/http://www.digitaljournal.com/article/282200

The government released information on Saturday that two people in China have died after receiving the H1N1 Swine Flu vaccination.

Last week, *Digital Journal* reported that a Virginia teen was diagnosed with Guillain-Barre syndrome. A German news outlet released information that a French teenage girl was also diagnosed with the paralysis syndrome. Now, according to *China Daily*, two Chinese people have died from the H1N1 Swine Flu vaccine.

The government issued a statement on Saturday saying that the two Chinese citizens died after receiving a domestically manufactured H1N1 vaccine. A preliminary report concludes that one of the victims suffered a sudden cardiac death, however the results of the second victim are still being processed, reports the *Sunday Pioneer*.

A spokesperson for the Health Ministry, Deng Haihua, said, according to *Channel News Asia*, "Specialists say that it is unavoidable that several serious adverse reactions will happen amid the more than 10 million people who have received the vaccine, and the 20, 30, 150 million who will in the future."

As the *Associated Press* notes, China's Health Ministry has stated that 43 deaths have occurred from the Swine Flu and more than 65,000 cases have been reported.

Six transported to hospital after getting swine flu vaccine

Khon2, 16 November 2009, 9:13 pm
https://web.archive.org/web/20111017124508/http://www.khon2.com/news/local/story/Six-transported-to-hospital-after-getting-swine/MDhKbCgfzUSC81KFtC_S1g.cspx

Officials say the apparent reactions could have a lot to do with anxiety rather than the vaccine itself.

Approximately 300 students and 100 faculty at Sacred Hearts Academy got armed against the H1N1 swine flu Monday morning in the State's school vaccination clinic.

Kindergartener Tai Martinez was one of those students.

"Under the recommendations of her pediatrician we felt confident," said Tai's mother Jade Martinez.

But school officials say about a dozen people had an apparent reaction minutes after getting vaccinated.

"It ranged from a rash on the arm, to breathing problems, their neck tightened up. A couple became nauseous. The most common complaint was light headedness," said Betty White, Head of Sacred Hearts Academy.

The clinic manager called EMS four times, and altogether paramedics took five students and one adult to the hospital.

All were released by noon, except for one student who has asthma.

When asked if she thinks they overreacted, State Epidemiologist Sarah Park said: "I think we're still looking into things but it does sound like probably we could've been a little been less reactive."

Park says according to protocol, she and a state pediatrician are standing by to answer any questions by phone.

"But if she's, if any of our clinic managers are in a pinch and they have to make a decision and they're not certain then yes the protocol is to call EMS for help," said Park.

Park says the clinic manager was new, and that the symptoms were actually side effects sometimes seen at the seasonal flu clinics, often due to anxiety and nerves.

"Bottom line for today -- what we heard about was not unusual. the only unusual thing was that they were clustered but anything with the kids they're fine it was a matter of being safe than sorry," said Park.

The Health Department began its H1N1 vaccination clinics on Friday and today held five clinics at schools across Oahu.

Officials say none of the other clinics reported any problems.

CBC news

2 Manitobans die within week of H1N1 shot

CBC News, 17 November 2009, 6:58 PM CT
https://web.archive.org/web/20091121104127/http://www.cbc.ca/canada/manitoba/story/2009/11/17/man-h1n1-adverse.html

Manitoba health officials are investigating the deaths of two people who died within a week of getting the H1N1 vaccine shot.

However, the province's top doctor said it's unlikely the vaccine caused their deaths.

There have been 69 "adverse events" after people received the swine flu shot, and eight were considered serious, Dr. Joel Kettner said, adding that figure falls within the expected range of reaction to the vaccine.

The Public Health Agency of Canada describes serious adverse events as:

- Events that cause life-threatening reactions such as anaphylaxis, where the body experiences a massive allergic reaction or convulsions brought on by fever.
- Events that trigger neurological reactions such as Guillain-Barré syndrome, where a person experiences a sudden onset of weakness or paralysis.
- Events that result in hospitalization, disability, birth defects or death.

The PHAC says serious adverse events following immunization are rare.

More than 200,000 people in the province have received the vaccine since clinics opened in late October.

No information about the people who died, including their ages and where they lived, has been released by the province.

CBC news

Elderly man dies after H1N1 shot
Serious reactions 'very rare,' official says

CBC News, 17 November 2009, 7:38 PM ET
https://web.archive.org/web/20091121133247/http://www.cbc.ca/canada/montreal/story/2009/11/17/vaccine-death-quebec.html
https://web.archive.org/web/20091121074801/http://news.aol.ca/article/elderly-man-dies-after-h1n1-shot/740345/

A Quebec man in his 80s died after being vaccinated against swine flu, officials said Tuesday.

They said it was too soon to determine whether the vaccine played a role in the death of the man, who had underlying health issues.

Quebec's director of public health protection, Dr. Horacio Arruda, declined to say what region the man was from or when he died, citing confidentiality concerns.

Arruda could not say why the man had received the vaccine. People over the age of 65 are not among the priority groups currently being vaccinated in the province.

He said final test results to confirm whether the vaccine played a role in the man’s death are expected in December.

Arruda said he was confident the incident would not discourage people from being vaccinated against H1N1 flu.

"I understand that everyone is worried," Arruda said, but stressed that serious reactions are "very rare phenomena."

Fewer than 1 in 100,000

Out of 6.6 million H1N1 vaccinations, there have been 36 reported serious adverse reactions to the vaccine in Canada, including the possible death, as of Nov. 7, said Dr. David Butler-Jones, Canada’s chief public health officer.

Butler-Jones told an Ottawa news conference that the number of reactions is below one serious adverse event per 100,000 people, which is in line with what officials expected.

"Actually the reactions so far to the pandemic vaccine had been less than we normally see with the seasonal vaccine," Butler-Jones said.

Butler-Jones said most of the serious problems have been anaphylactic reactions – massive allergic responses that can be life-threatening – o convulsions brought on by fever.

The vast majority of reactions to the vaccine are minor, he emphasized, such as a sore arm, a mild fever and malaise.

Federal Health Minister Leona Aglukkaq said Canadians are doing "the right thing" by being vaccinated.

"National and international data is showing that the vaccine is producing an immune response of about 94 per cent in people who receive it," Aglukkaq said. "This is remarkable because normally response to the vaccine for the seasonal flu is about 60 to 80 per cent."

So far in Quebec 37 people have died of complications related to the flu since Aug. 30, while more than 1,500 have been hospitalized.

Schweinegrippe Impfung: Nebenwirkungen nach der Immunisierung?

CECU, 17 November 2009
https://web.archive.org/web/20091121191326/http://www.cecu.de/1011+M584b1e7e40f.html

Der Tod eines Mannes nach der Schweinegrippe Impfung wirft Fragen nach möglichen Nebenwirkungen auf. Allein in Thüringen sind drei Menschen nach der Impfung gestorben. Der genaue Zusammenhang zwischen dem Tod und der Schweinegrippe Impfung wird noch untersucht.

Welche Nebenwirkungen können durch die Schweinegrippe-Impfung hervorgerufen werden? Grundsätzlich handelt es sich bei dem verwendeten Impfstoff Pandemrix um einen von der europäischen Zulassungsbehörde genehmigten Impfstoff. Die Nebenwirkungen bewegen sich nach Herstellerangaben im Bereich der üblichen Folgewirkungen bei Impfungen.

Dazu zählen Lokalreaktionen an der Injektionsstelle sowie allgemeine Reaktionen nach einer Impfung (Fieber, Müdigkeit, Kopf- und Gliederschmerzen, Übelkeit, Lymphknotenschwellung). Insgesamt listet das Paul-Ehrlich-Institut (PEI) knapp 200 Fälle auf, bei denen es zu Impfreaktionen nach der Schweinegrippe-Impfung gekommen ist.

Teilweise sind allergische Reaktionen und Kreislaufbeschwerden zu verzeichnen. Bisher konnte kein Zusammenhang zwischen der Schweinegrippe-Impfung und dem Tod nach der Impfung festgestellt werden. Insofern können bisher keine verlässlichen Aussagen darüber getroffen werden, ob die Schweinegrippe Impfung unerwünschte und gefährliche Nebenwirkungen haben kann.

THE FLU CASE

Three people alone die in Thuringia, Germany, after jab

The Flu Case, 17 November 2009 09:53
https://web.archive.org/web/20100102030402/http://theflucase.com/index.php?option=com_content&view=article&id=1829%3Athree-people-alone-die-in-thuringia-germany-after-jab&catid=1%3Alatest-news&Itemid=64&lang=en

Three people have died in the German state of Thuringian after the swine flu jab, according to the local media.

The Paul Ehrlich Institute, the drug government regulator which recommended the swine flu jab in spite of the fact it has not been tested, has received 200 reports about people dying or falling sick following the jab. However, the Paul Ehrlich Institute has said it has failed to find any link between the jab and the damage so far allowing the murder to continue.

Bild

Schon 7 Tote nach Impfung: Ärzte raten trotzdem zur Vorsorge

BILD, 17 November 2009, 20:09 UHR
https://web.archive.org/web/20091130231830/http://www.bild.de:80/BILD/news/2009/11/17/schweinegrippe/schon-sieben-tote-nach-impfung.html

Ist der Impfstoff gegen die Schweinegrippe doch riskanter als bislang bekannt?

Nach BILD-Informationen starben in den vergangenen drei Wochen mindestens sieben Menschen in Deutschland nach der Impfung mit "Pandemrix".

Unter den Toten ist auch ein Kleinkind. Der Junge (21 Monate) litt an einem schweren angeborenen Herzfehler und dadurch an einer stark eingeschränkten Funktion der Lunge. Er war für eine Herz- und Lungentransplantation vorgesehen und entwickelte rund 30 Stunden nach der Impfung leichtes Fieber und Unruhe. Dabei erlitt er einen Lungeninfarkt, starb einen Tag nach der Impfung trotz künstlicher Beatmung.

Dr. Susanne Stöcker, Sprecherin des Paul-Ehrlich-Instituts: "Wenn nach der Impfung etwas geschieht, heißt es nicht, dass es zwangsläufig durch die Impfung geschieht. Gerade bei schwer kranken Risikopatienten, denen die Impfung empfohlen wird, ist es möglich, dass sie an ihrer Vorerkrankung sterben und die Impfung damit nichts zu tun hat."

Die Verdachtsfälle

• Eine Frau (65) aus Weimar (Thüringen) erlitt nach der Impfung einen Herzinfarkt. Der Amtsarzt schloss einen Zusammenhang mit der Impfung aus, da die Frau mehrere Vorerkrankungen hatte. Eine Obduktion gab es nicht.

• Ein Mitarbeiter (46) von Bayer wurde tot auf der Toilette gefunden, einen Tag nach der Impfung. Die Obduktion ergab: plötzlicher Herztod.

• Berufsschullehrer Franz K. (55, 2 Kinder) aus Leinefelde (Thüringen) ließ sich nachmittags impfen. Sechs Stunden später starb er zu Hause. Todesursache: ein Herzinfarkt, der schon vor der Impfung begonnen hatte. Die Amtsärztin: "Ein Einfluss der Impfung auf den Tod des Mannes ist nicht abzuleiten."

• Eine 92-Jährige starb drei Tage nach der Impfung.

• Eine 65-Jährige aus Wuppertal (NRW) starb zwei Tage nach der Impfung. Sie war Diabetikerin.

• Gestern wurde ein Mann (66) tot in seiner Wohnung in Mühlhausen (Thüringen) gefunden. Er litt unter Atemwegserkrankungen, hatte sich am Freitag impfen lassen.

Ist der Impfstoff doch gefährlich?

Dr. Susanne Stöcker vom Paul-Ehrlich-Institut: "Nein, nach derzeitigem Kenntnisstand ist der Nutzen der Impfung höher als das Risiko."

Und für Kinder? Dr. med. Wolfram Hartmann, Präsident des Berufsverbandes der Kinder- und Jugendärzte: "Nein. Ich habe die Berichte von mehreren Hundert Kinderärzten aus ganz Europa bekommen. Die Impfung wird gut vertragen, es gibt keine Komplikationen. Von dem Fall des Kleinkindes hab ich noch nichts gehört."

Thüringens Gesundheitsministerin Heike Taubert (SPD), Vorsitzende der Gesundheitsminister-konferenz, appelliert gestern erneut an die Bundesbürger, sich impfen zu lassen.

THE FLU CASE

BILD admits at least 7 people have died in Germany so far from the swine flu jab

The Flu Case, 17 November 2009, 09:59
https://web.archive.org/web/20100102022921/http://theflucase.com/index.php?option=com_content&view=article&id=1830%3Abild-admits-at-least-7-people-have-died-in-germany-so-far-from-the-swine-flu-jab&catid=41%3Ahighlighted-news&Itemid=105&lang=en

After defending the swine flu jab in its hit piece report yesterday, the German newspaper BILD today admits that at least seven people have died so far in Germany following an injection with Pandemrix, manufactured by GlaxoSmithKline, and classified as a bioweapon by EU and US regulators according to the indices in biopharma databases.

BILD reports that a 21-month-old boy died following the jab but maintains this was due to heart problems, ignoring the fact the swine flu jab is recommended for the chronically ill too.

Charlie Fidelman

Quebec man dies after H1N1 shot
Health officials investigate, but say it's too soon to link fatality to flu vaccine

Canada.com, 18 November 2009
https://web.archive.org/web/20091121174733/http://www.canada.com/health/Quebec+dies+after+H1N1+shot/2237555/story.html
https://web.archive.org/web/20091125004609/http://www.montrealgazette.com/health/Quebec+dies+after+H1N1+vaccination/2235127/story.html

Montreal – Health officials are investigating the death of an elderly Quebec man following vaccination against H1N1 flu.

But officials said it is too early to determine whether the man, believed to be in his 80s, succumbed to underlying health conditions or whether the vaccine played a role in his death.

The man died sometime in the last three weeks, but the provincial health department refused to give details, citing confidentiality.

Speaking at the daily briefing in Quebec City, Dr. Horacio Arruda, director of the protection branch of the Quebec Public Health agency, declined to provide such information as the victim's age, in which region he lived and whether he died shortly after inoculation or days later.

Most allergic reactions occur immediately, which is why people are asked to remain at vaccine centres for 15 minutes following inoculation. "We can't say there is a causal association between the death and the flu shot," Arruda said, echoing comments made earlier by Dr. David Butler-Jones, Canada's chief public health officer.

"It's important to remember that just because a medical event follows vaccination, it may not have been caused by the vaccination; it may have been caused by other factors, as unfortunate events continue to occur with or without vaccine," Butler-Jones told a news conference.

The total number of deaths in Canada resulting from complications related to the flu has reached 198.

But health officials stress that only a small number of Canadians have suffered serious side effects from the swine flu shot. Of the 6.6 million doses administered, a total of 36 people suffered severe reactions causing life-threatening illness, convulsions, disability or death. In Quebec, the number of reactions have reached 23, including one death.

Quebec's surveillance team reported the death to Health Canada, which is tracking adverse reactions to the vaccine.

"But that's an extremely rare phenomena, and most people have no problems," Arruda said.

Side effects are expected during any mass immunization program, but the benefits of vaccination outweigh the risks. "It's better to get the flu shot than to get the disease," Arruda said.

In Quebec, the rate of severe side effects cases is below what is expected – less than one event per 100,000 shots, Arruda said. While there might not be vaccines for everyone right away, Health Minister Yves Bolduc said that there will be enough for those who want to get immunized before Christmas.

So far, more than 1.5 million Quebecers have been vaccinated, he said.

The Free Press

Serious side-effects to H1N1 vaccine rare

The Free Press, 18 November 2009, 1:00 AM CST
https://www.winnipegfreepress.com/local/2009/11/18/serious-side-effects-to-h1n1-vaccine-rare

Ottawa – The chief public health officer says few Canadians have suffered serious side-effects from the H1N1 flu shot.

Dr. David Butler-Jones says that of the 6.5 million people who have received the H1N1 vaccine, only 36 have had serious adverse reactions.

"With any vaccination campaign, we expect to see some cases of serious adverse events," he said. "They are very rare, but they are part of all mass-vaccination campaigns and we expect to see a small number of them."

More serious reactions can include life-threatening illnesses, disabilities or deaths.

One person is believed to have died from a serious reaction to the vaccine, Butler-Jones said, but the death hasn't yet been conclusively linked to the flu shot. He said it's possible the elderly person who died suffered from an underlying condition.

CTV reported Tuesday it had been told by Manitoba health officials about the deaths of two people in the province within a week of getting the H1N1 vaccine.

The provincial officials said the H1N1 immunizations were not likely the cause of the death in either case.

"Like all drugs, medicines, operations, there is nothing that is absolutely free of risk," said provincial health officer Dr. Joel Kettner. "The big question always is, does the benefit that one is expected to get from this vaccine significantly outweigh the risks?"

All the serious side-effects came after shots of the adjuvanted vaccine, which contains a compound to boost the vaccine's potency. Butler-Jones said that's likely because the majority of people are getting the adjuvanted vaccine.

A version of the vaccine without the booster is being held for pregnant women.

Butler-Jones said the serious side-effects from the H1N1 shot fall into two categories: allergic reactions, or fevers and convulsions.

Mild effects, such as nausea, soreness, headaches and fever, are far more common reactions to the shot.

The government says it will list adverse reactions to the shot on its www.fightflu.ca website.

So far, 198 people have died of H1N1 flu. By comparison, seasonal flu kills between 4,000 to 8,000 Canadians each year.

– The Canadian Press

THE FLU CASE

Unconfirmed reports of large numbers of deaths from the vaccine in the Ukraine

The Flu Case, 19 November 2009, 20:03
https://web.archive.org/web/20100102014447/http://theflucase.com/index.php?option=com_content&view=article&id=1977%3Aunconfirmed-reports-of-thousands-dead-from-the-vaccine-in-the-ukraine&catid=41%3Ahighlighted-news&Itemid=105&lang=en

Unconfirmed reports are coming in that thousands of people in what appears to be a rural area under quarantine in the western Ukraine have been killed by vaccines.

A Ukrainian woman who crossed into neighbouring Poland told people there that she had driven into the Ukraine to meet a friend but was stopped about 60 km from the border and told that parts of the Western Ukraine were closed at a distance of about 100 kilometers from the border with Poland.

These people allegedly told her that there were thousands of dead people lying on the streets inside those closed off areas.

Also, there are mass graves filled with bodies covered with lime. The woman said the people had died as a result of vaccinations. The vaccines allegedly came from France.

This report cannot be independently verified. The woman has reported what others have told her leaving room for the story to be distorted if there is any basis in fact at all. The woman did not see these things with her own eyes.

Life in the town of Drohobych in the Western Ukraine appears to be continuing as normal, say eyewitness reports from there.

The Ukrainian government has recently clamped down on the media, shutting down bloggers, and there are no reports so far in the mainstream or alternaitve media that confirm this story.

Rural parts of Western Ukraine are difficult to access.

The Ukrainian government has said that it has put parts of Western Ukraine under quarantine as a result of an outbreak of pandemic. Also, the government has announced its intention to carry out mass vaccinations under the instructions of WHO to counter the "pandemic".

Reports have come in of pneunomic plague following unusual aircraft activity.

Doctors are reported to have been told that they cannot write down pneumonic plague as a cause of death and must write down swine flu.

This is an email from a source in Poland:

I reveived a phone call from the friend of my parents, a healer, who had a client from Ukraine - woman, who allegedly ran away from Ukraine yesterday.

What she says is very scary. She tried to drive into Ukraine to meet her friend.

About 60 km from the border, she was stopped by people. They warned her that some parts of Western Ukraine are closed, around 100-10 km from the border.

Those people allegedly were crying that there are thousands of dead victims lying on the streets, and nobody wants to touch them.

Also, that there are some mass graves filled with bodies, which were disinfected with lime (calcium). Thousands of people died not from the disease but from the vaccines.

I tried to verify this info, my cousin called friends in Drohobycz (also Western Ukraine) - there is nothng abnormal there. So, it could be a provocation or to run false stories.

Of course, there is a chance that only small part of the region is affected, maybe they tried their untested vaccine and these are the results.

Nevertheless, there is complete media blackout about it except some comments in my blog which for already 2 weeks confirm the fact of "thousands of victims".

World Health Organization

Safety of pandemic vaccines
Pandemic (H1N1) 2009 briefing note 16

Geneva, WHO, 19 November 2009

https://web.archive.org/web/20091231140429/http://www.who.int/csr/disease/swineflu/notes/briefing_20091119/en/index.html

Pandemic (H1N1) 2009 briefing note 16

GENEVA, 19 November 2009 – To date, WHO has received vaccination information from 16 of around 40 countries conducting national H1N1 pandemic vaccine campaigns. Based on information in these 16 countries, WHO estimates that around 80 million doses of pandemic vaccine have been distributed and around 65 million people have been vaccinated. National immunization campaigns began in Australia and the People's Republic of China in late September.

Vaccination campaigns currently under way to protect populations from pandemic influenza are among the largest in the history of several countries, and numbers are growing daily. Given this scale of vaccine administration, at least some rare adverse reactions, not detectable during even large clinical trials, could occur, underscoring the need for rigorous monitoring of safety. Results to date are encouraging.

Common side effects

As anticipated, side effects commonly reported include swelling, redness, or pain at the injection site, which usually resolves spontaneously a short time after vaccination.

Fever, headache, fatigue, and muscle aches, occurring shortly after vaccine administration, have also been reported, though with less frequency. These symptoms also resolve spontaneously, usually within 48 hours. In addition, a variety of allergic reactions has been observed. The frequency of these reactions is well within the expected range.

Guillain-Barre syndrome

To date, fewer than ten suspected cases of Guillain-Barre syndrome have been reported in people who have received vaccine. These numbers are in line with normal background rates of this illness, as reported in a recent study. Nonetheless, all such cases are being investigated to determine whether these are randomly occurring events or if they might be associated with vaccination.

WHO has received no reports of fatal outcomes among suspected or confirmed cases of Guillain-Barre syndrome detected since vaccination campaigns began. All cases have recovered. WHO recommends continued active monitoring for Guillain-Barre syndrome.

Investigations of deaths

A small number of deaths have occurred in people who have been vaccinated. All such deaths, reported to WHO, have been promptly investigated. Although some investigations are ongoing, results of completed investigations reported to WHO have ruled out a direct link to pandemic vaccine as the cause of death.

In China, for example, where more than 11 million doses of pandemic vaccine have been administered, health authorities have informed WHO of 15 cases of severe side effects and two deaths that occurred following vaccination. Thorough investigation of these deaths, including a review of autopsy results, determined that underlying medical conditions were the cause of death, and not the vaccine.

Safety profile of different vaccines

Campaigns are using nonadjuvanted inactivated vaccines, adjuvanted inactivated vaccines, and live attenuated vaccines. No differences in the safety profile of severe adverse events among different vaccines have been detected to date.

Although intense monitoring of vaccine safety continues, all data compiled to date indicate that pandemic vaccines match the excellent safety profile of seasonal influenza vaccines, which have been used for more than 60 years.

THE FLU CASE

Canadian authorities admit "higher than average" anaphylactic reactions to swine flu jab

The Flu Case, 19 November 2009, 13:04

https://web.archive.org/web/20100102045750/http://theflucase.com/index.php?option=com_content&view=article&id=1874%3Acanadian-authorities-admit-qhigher-than-averageq-anaphylactic-reactions-to-swine-flu-jab&catid=1%3Alatest-news&Itemid=64&lang=en

Authorities in the Canadian province of British Columbia have noted a higher-than-average number of anaphylactic reactions in people who have had the pandemic flu vaccine.

Anaphylaxis is a sudden allergic reaction that can involve hives, swelling around the eyes or mouth, difficulty breathing or swallowing and a sudden blood pressure drop. It requires immediate treatment and can be life-threatening. A certain number of anaphylactic reactions are expected and normal in large-scale vaccination campaigns, which reach millions of people.

British Columbia has reported around twice as many reactions so far than are usually sees in typical flu vaccine campaigns. Nevertheless, these figures are still within normal range. No one has died.

Health officials are investigating the cases, which as of yet have no identified pattern. They have occurred in people using both adjuvanted and unadjuvanted H1N1 vaccines. Some of them received a pandemic and seasonal flu vaccine at the same visit even though there is no data on how safet this is.

Deaths not linked to H1N1 vaccine: WHO

Reuters, 19 November 2009, 8:23 pm

http://www.reuters.com/article/idUSTRE5AI2BL20091119?feedType=RSS&feedName=he

Geneva (Reuters) **-** The World Health Organization said on Thursday the H1N1 vaccine had been cleared of blame for 41 deaths which health authorities worldwide had investigated after suspicions they might have been caused by the inoculation.

The U.N. agency reaffirmed that the pandemic vaccine is as safe as the seasonal flu vaccine used for more than 60 years. It also voiced concern that some pregnant women and others at risk were shunning it because of a fear of side-effects.

"No new safety issue has been identified from reports issued to date ... Reporting so far reconfirms that the pandemic flu vaccine is as safe as the seasonal flu vaccine," Marie-Paule Kieny, WHO's top vaccine expert, told a telephone conference.

Governments have so far reported that 65 million vaccine doses have been administered against H1N1, known as swine flu, in 16 countries, but the true figure is probably higher since immunization campaigns are under way in 40 countries, she said.

Side-effects commonly reported include swelling and redness or pain at the injection site, although some had fever or headache, and all symptoms usually disappear after 48 hours.

A "small number of deaths" had been reported, she said, and a WHO spokeswoman later put the figure at 41 in six countries.

"Although some investigations are still ongoing, the results of the completed investigations reported to WHO have ruled out that the pandemic vaccine is the cause of death," Kieny said.

Authorities in China – where 11 million people have been vaccinated -- have reported 2 deaths following inoculation and 15 cases of severe side effects, the WHO said in a statement.

"Thorough investigation of these deaths, including a review of autopsy results, determined that underlying medical conditions were the cause of death and not the vaccine," it said of China.

Fewer than a dozen suspected cases of Guillain-Barre syndrome had been reported following pandemic vaccination, she said. "Only a few of this Guillain-Barre may be linked to the pandemic vaccine .... and patients have recovered," she added.

"No Significant Difference"

GlaxoSmithKline Plc, AstraZeneca Plc, Novartis and Sanofi-Aventis are among about 25 manufacturers producing H1N1 vaccine using different techniques.

"No significant difference in the safety profile between different types of vaccine has been detected," Kieny said.

She denounced conspiracy theories about vaccines circulating on the Internet, saying they were causing "artificial worries."

"We have to reiterate that the vaccines are safe, that the disease in certain people can be severe and can be cause of death," she said.

The H1N1 virus is known to have killed 6,250 people worldwide since emerging in North America last April, according to the WHO.

A survey of doctors showed on Wednesday that more than half of Britons being offered vaccination against H1N1 were turning it down because they feared side-effects or believed the virus was too mild to bother about.

"It is worrying indeed that certain groups don't seem to be coming readily to be vaccinated. But we hope that the data ... on the safety of these vaccines will dissipate the worries that a population might have and will help convince them that the vaccine is safe and vaccination will protect them against this disease which can be severe," Kieny said.

INDEPENDENT

WHO plays down reported swine flu vaccination deaths

Independent, 19 November 2009, 01:00
https://www.independent.co.uk/life-style/health-and-families/health-news/who-plays-down-reported-swine-flu-vaccination-deaths-5507829.html

The World Health Organisation said Thursday that checks on many of the 30 deaths recorded following mass pandemic flu vaccinations had so far ruled out a direct link to the vaccines.

"Although some investigations are still ongoing, results of completed investigations reported to WHO have ruled out that the pandemic vaccine is a cause of death," said Marie-Paule Kieny, the WHO's director for vaccine research, she added.

The fatalities made up a minute fraction of at least 65 million doses of swine flu vaccines which have been administered, said the WHO, citing data from 16 countries.

For every 10,000 doses of vaccines administered, only one report of adverse effect had been logged.

Of every 100 reports of adverse effects, five are serious cases such as death, added Kieny.

"The reports so far confirmed that the pandemic vaccine is as safe as the seasonal flu vaccine," she said.

Vaccination programmes have been rolled out across some 40 countries, and the WHO is planning to start delivering vaccines at the end of November to poorer countries.

Kieny acknowledged that there was a "few days' delay" in delivery of these vaccines to some 95 countries, but added that they should get the drugs over the next three months.

The A(H1N1) pandemic has claimed over 6,250 lives since the virus was first uncovered in April.

Quebec man dies after taking H1N1 vaccine

Digital Journal, 19 November 2009
https://web.archive.org/web/20091124024520/http://www.digitaljournal.com/article/282399

On Tuesday, an 80-year-old Quebec man died after taking the H1N1 Swine Flu vaccination but health officials are stating that it's too soon to link the death and vaccine.

Digital Journal reported last week that two people in China died after receiving the H1N1 Swine Flu vaccination and others have been diagnosed with Guillain Barre Syndrome but now an 80-year-old man in Montreal died after taking the H1N1 vaccine, according to *CBC*.

Quebec's Director of Public Health Protection, Dr. Horacio Arruda, did not know why the man took the vaccine and that final test results, which are expected to come in December, will determine whether or not the man died from the vaccine.

Canada.com reports the man died in the last three weeks but provincial officials declined to reveal details, citing confidentiality concerns. Arruda has said that most allergic reactions occur right away, which is the reason why many patients are asked to stay in the centers, "We can't say there is a causal association between the death and the flu shot."

Nevertheless, Arruda is confident that the death will not discourage people from taking the vaccine but urged that serious reactions to the H1N1 shot are rare, "I understand that everyone is worried."

Canada's Chief Public Health Officer, Dr. David Butler-Jones, also concurred with Arruda, "It's important to remember that just because a medical event follows vaccination, it may not have been caused by the vaccination; it may have been caused by other factors, as unfortunate events continue to occur with or without vaccine."

The Federal Health Minister Leona Aglukkaq assured Canadians that they're doing the right thing, *AOL News* reports, "It's important to remember that just because a medical event follows vaccination, it may not have been caused by the vaccination; it may have been caused by other factors, as unfortunate events continue to occur with or without vaccine. This is remarkable because normally response to the vaccine for the seasonal flu is about 60 to 80 per cent."

The Montreal Gazette notes that public health officials have stated that only a small number of Canadians have suffered side effects from the H1N1 vaccine. 23 Quebecers have reacted negatively to the shot, including one death and 37 have died from the flu.

Currently, 1.5 million citizens of Quebec have been vaccinated since August 30 and more than 1,500 have been hospitalized.

THE CANADIAN PRESS

Family questions if H1N1 shot caused Manitoba woman's death

The Canadian Press, 19 November 2009, 8:27 AM ET
CTV News, 22 November 2009
https://web.archive.org/web/20091122094301/https://www.ctv.ca/servlet/ArticleNews/story/CTVNews/20091119/h1n1_death_091119/20091119?hub=Health

Winnipeg – The family of a 38-year-old Manitoba woman who died five days after receiving the H1N1 vaccine are looking for answers as to why it happened.

Soo Lee Wong and her daughter, Angela Truong, both got the H1N1 shot on November 5th.

The family says Wong, who had diabetes, started getting sick a day after getting vaccinated and died a few days later.

Doctors told the family Wong died of a blood infection. More tests will be done to see if the vaccine played any role.

Wong's husband, Thoon Truong, is also caring for his seven-year-old daughter Angela, who has been in the hospital with a fever and swollen, painful legs.

He wants to know whether the two cases related to the vaccine or to something else.

The province is currently investigating two deaths -- both adults who died within seven days of getting the H1N1 shot.

Although it's still early, Manitoba's chief medical officer of health Dr. Joel Kettner says immunizations were not likely the cause of the deaths.

Прививка от свиного гриппа не может быть причиной смерти

Deutsche welle, 20 ноября 2009
https://www.dw.com/ru/privivka-ot-svinogo-grippa-ne-mozhet-byt-prichinoj-smerti/a-4911215

Эксперты Всемирной организации здравоохранения провели исследование 41 смертных случаев, причиной которых, по мнению медиков, могли стать прививки вакциной от свиного гриппа. К вакцинации все эти случаи, уверены специалисты ВОЗ, не имеют никакого отношения.

Всемирная организация здравоохранения (ВОЗ) в обнародованном в пятницу, 20 ноября, докладе сообщила, что прививка от вируса A(H1N1) не может являться причиной летального исхода. ВОЗ изучила более 40 случаев, зарегистрированных в шести странах, когда люди умирали вскоре после вакцинации, пишет агентство Reuters. Эксперт организации Мари-Поль Кьени заявила, что прививка от свиного гриппа настолько же безопасна, как и вакцины против других вирусов гриппа. "Поступавшие до сих пор в наше распоряжение сведения не вызывают опасений относительно безопасности вакцины", - заявила специалист по прививкам. Крупнейшими производителями вакцины от вируса A(H1N1) в настоящий момент являются фармацевтические концерны GlaxoSmithKline, AstraZeneca, Novartis и Sanofi-Aventis.

Симптомы инфекционного заражения проходят

По данным ВОЗ, по всему миру вакцинацию от свиного гриппа уже прошли 65 миллионов человек, сообщает dpa. При этом эксперты указывают, что после прививки у многих на месте укола возникают небольшие опухоли, покраснения, а также боли, которые вскоре проходят. Несколько реже у прошедших вакцинацию наблюдаются повышение температуры, головные боли, усталость и мышечные боли. Эти симптомы как правило проходят в течение двух дней.

Информацию о последствии прививок от свиного гриппа ВОЗ предоставили 16 из 40 стран, где проводится вакцинация. На основании поступавших до сих пор данных медики делают вывод о том, что вакцина от вируса A(H1N1) обеспечивает такой же высокий уровень иммунитета, как и обычные прививки от гриппа, применявшиеся на протяжении последних 60 лет.

THE FLU CASE

WHO denies vaccines are causing deaths: dismisses "conspiracy theories" as "artificial worries"

The Flu Case, 20 November 2009, 15:18
https://web.archive.org/web/20100102005622/http://theflucase.com/index.php?option=com_content&view=article&id=1988%3Awho-denies-vaccines-are-causing-deaths-dismisses-qconspiracy-theoriesq-as-qartificial-worriesq&catid=1%3Alatest-news&Itemid=64&lang=en

The WHO press strategy to deal with reports of growing numbers of deaths and damage caused by their mass swine flu vaccination programme appears be to invite members of the controlled media to their press briefings.

These reporters allow WHO a free hand to trumpet its claim there is no link between the swine flu jabs and the deaths of otherwise healthy people who took them, even though such a link is being reported by doctors all over Europe.

Attending a WHO press briefing on Thursday was a journalist from Reuters, the very same agency that reported that the third World Trade Center Tower had fallen on September 9/11 about 20 minutes before it, in fact, collapsed.

This verifiably false Reuters report was read out by a BBC anchor sitting in a studio with the Third Tower clearly visible behind her in an Orwellian propaganda moment.

Also, attending the WHO press briefing yesterday was a reporter from Bloomberg, the news agency founded by Michael Bloomberg, who became mayor of New York in 2001 and so helped cover up l the evidence that the WTC towers were destroyed by explosives planted by insiders.

Canwest and the Telegraph, a Rothschild-family controlled asset, sent their reporters along.

The transcript of this press conference can be read on at
https://web.archive.org/web/20091129180427/http://www.who.int/mediacentre/vpc_transcript_19_november_09_kieny.pdf

WHO's spokesperson Dr Marie-Paul Kieny makes verifably false statements about the safety of the vaccine but not a single reporter picks her up on these.

Kierny repeatedly states that the swine flu vaccine is safe, as safe as the seasonal flu vaccine.

However, there are no clinical trial data on the safety of the swine flu vaccines according to documents on the European Medicines Agency's own website.

These vaccines have been allowed to be used in spite of the fact there are no tests on their safety on the grounds that there is a "pandemic emergency", which many doctors and health experts have questioned given the fact the swine flu is milder than the seasonal flu.

No reporter picks Kierny up on the fact that her statement that the vaccines are safe has absolutely no basis in fact.

These new and untested vaccines have been allowed to be administerd to the people of Europe only on condition that governments monitor their safety continues.

However, the surveillance system set up with the help of WHO makes no attempt at any serious monitoring. There *is no requirement to report* deaths or damage from the swine flu jab.

https://web.archive.org/web/20090619001425/http://www.mhra.gov.uk/Safetyinformation/Swinefluinformation/index.htm

Anyone wishing to report a side effectt to the MHRA in the UK, has to register on the website and fill out a yellow card that takes fifteen minutes of your time.

The difficulty of reporting a side effect of the swine flu jab are in strong contrast to the huge numbers of hotlines and swine flu centers that sprung up all around the UK this ummer. Anyone ringing up with a fever was diagnosed as having swine flu and given a code that gave them access to free Tamiflu.

Whenever doctors and patients do report side effects of vaccines to authorities, the authorities are quick to dismiss any link with the vaccine.

The WHO did the same on Thursday:

"A small number of deaths have occurred following vaccine administration. All such deaths, reported to WHO, have been investigated by the countries. Although some investigations are still on-going, results of the completed investigations reported to WHO have ruled out that the pandemic vaccine is the cause of death."

WHO claims there have been 65 million doses of swine flu administered but a careful look at the figures in Europe suggest about a million doses have been administered – as opppsed to distributed – altogether.

No reporter picks Kieny on why there is no requirement for governments to keep track of how many jabs have been given as opposed to distributed.

No reporter asks about why pharma executives sit on WHO's SAGE vaccine advisory board or how independent the European drug regulator, the EMEA, is if it is two thirds funded by pharma companies.

Jason Gale of Bloomberg asks about "conspiracy theories" implying that the view that WHO and big pharma are pushing on the world a dangerous and untested jab for profit has no basis in fact when it does.

Anyone can check for themselves by going to the EMEA website and reading the package inserts and the product information on the swine flu jabs from Baxter, Novartis and GlaxoSmithKline and see there have been inadequate or no clinical trials completed, though a couple on pregnant women and kids have just begun.

Anyone can read the EMEA pandemic emergency vaccine approval regulations and see that the vaccines do not need to be shown to be safe and effective before being approved.

WHO loosened the pandemic criteria in April to allow a pandemic level 6 declaration is a fact that anyone can check.

No reporter asked about why a pandemic had been declared when there was so much evidence that the swine flu was milder than the seasonal flu.

It is a fact that pharmaceutical executives sat as observers on WHO's vaccine advisory board which recommended the swine flu jab with toxic mercury and adjuvants.

And yet none of the reporters asked any questions about the links between WHO and pharma.

None of the reporters asked about how come key government health advisors recommending the swine flu vaccines have financial links to pharmaceutical companies making that same vaccine.

The fact that WHO is pushing on people an untested and toxic jab are presented as "artificial worries" by Kieny and "conspiracy theories" that stop the general public from taking the jab and ensuring big pharma hefty profits.

"Marie-Paule Kieny: The conspiracy theories have indeed been brought to our attention.

We really think that these can be damaging and indeed there are worries which are artificial worries generated by these conspiracy theories. Really what we would like to do is that we have to reiterate that the vaccines are safe, that the disease in certain people can be severe and can be the cause of death and therefore this is not the time to discuss or try to work out whatever conspiracies there may be. This is a time to work together, to produce more, to distribute more and to protect as many people as possible against this pandemic virus."

Paul Turenne

Flu vaccine batch pulled in Manitoba
Higher rates of allergic reaction, says Kettner

Winnipeg Sun, 20 November 2009, 1:12:47 CST AM

https://web.archive.org/web/20110513210649/http://www.winnipegsun.com/news/manitoba/2009/11/20/11824636-sun.html

More than 900 unused doses of H1N1 vaccine have been pulled out of circulation in Manitoba after health authorities received word other vaccines from the same batch have been causing higher rates of allergic reactions than expected.

Dr. Joel Kettner, Manitoba's chief public health officer, said the Public Health Agency of Canada's monitoring of the H1N1 immunization program identified about 1 in 20,000 people in Manitoba were suffering severe allergic reactions to one particular lot of the vaccine, which is about five times the usual rate in other flu vaccines and what had been expected for the H1N1 shot.

"We've been asked by the manufacturer, GlaxoSmithKline, to not use this vaccine at this time," Kettner said. "Nobody knows if anything's wrong with it at all. All we've observed so far is a somewhat higher rate of anaphylactic reaction."

Kettner said the batch of vaccine in question was distributed across the country and other provinces are also being asked to hold whatever they have left of that lot.

In Manitoba, 63,000 doses from the lot arrived during the week of Oct. 19. It was distributed to clinics in Winnipeg, Brandon, and the Parkland and Northeastman health regions, as well as to a third-party organization. It was made available as of the first week of immunization, and the vast majority has been used up. Only 930 doses remain unused: 630 in Northeastman and 300 with the organization.

Kettner stressed anyone who would have suffered a reaction to the shot would have done so within 15 to 20 minutes of getting it, and there is no lasting danger to anyone who received a shot from the lot.

Three people in Manitoba suffered a severe anaphylactic reaction to the shot from that batch, all of whom were properly diagnosed and treated at their injection clinics, with none suffering any lasting effect, he said.

Meanwhile, Manitoba Health provided its weekly statistical update on the H1N1 flu yesterday, revealing 251 more cases have been confirmed in the past week, while another person with a confirmed case has died. It is the second death from H1N1 in Manitoba this fall and the ninth since the virus appeared in the spring.

The WRHA is advising its H1N1 immunization clinics will only be open to pregnant women and healthy people age 10 to 65 until it receives more adjuvanted vaccine. Its supply of adjuvanted vaccine will likely all be used up by early this morning, leaving it only with the unadjuvanted variety to use in its clinics today and tomorrow.

The unadjuvanted version is not recommended for children younger than 10, adults older than 65, or anyone with a weakened immune system.

The WRHA's 12 mass clinics will be open 9:30 a.m. to 4 p.m. today, while two special Saturday clinics will operate during those same hours tomorrow at the University of Manitoba and at the Holy Eucharist Parish Centre on Munroe Avenue.

More adjuvanted vaccine is expected to arrive in Manitoba early next week.

SVALBARDPOSTEN

Karine Nigar Aarskog

Mistet smaken etter vaksine

Svalbardposten, 20 November 2009, 08:00
https://www.svalbardposten.no/mistet-smaken-etter-vaksine/111932
https://web.archive.org/web/20100204030749/http://www.svalbardposten.no/nyheter/mistet-smaken-etter-vaksine

Silje Marie Våtvik mistet både smaks- og luktesansen etter å ha tatt vaksinen mot svineinfluensa. Hun har vært sykemeldt i flere uker.

– Folk forstår ikke hva det innebærer å ikke ha smak og lukt. Jeg smaker ikke maten og klarer derfor ikke å svelge den. Det hemmer meg også i det sosiale liv, fordi jeg ikke kan være med på middager, sier Silje Marie Våtvik (30).

30-åringen, som bor i Longyearbyen, var en av de første som fikk vaksinen mot svineinfluensa. Fordi hun jobber i SGS på flyplassen, og med det regnes som en del av beredskapen på øya, fikk hun tilbudet gjennom arbeidsgiveren allerede samme dag som den første ladningen vaksine var kommet, onsdag 21. oktober.

– Hadde jeg ikke blitt tilbudt vaksinen, ville jeg nok fortsatt vært i den gruppen som hadde sittet og spekulert på om jeg skulle ta den. Og det første jeg spurte om var bivirkningene, sier Våtvik.

Ingen svar

Det hun ikke var forberedt på, var at hun kunne miste både smaks- og luktesansen. Den har vært borte siden hun tok vaksinen. På sykehuset har de tatt alle slags prøver, uten at 30-åringen har fått noe svar.

– De holdt alle muligheter åpne for at det kunne være tilfeldig og ikke hadde noe med vaksinen å gjøre. Men det var til slutt bare den som stod igjen som en årsak, forteller hun.

Må til Tromsø

Fordi hun får i seg så lite mat, er Våtvik sykemeldt på ubestemt tid.

– Jeg tenker på mat hele tiden, har lite energi og er irritabel fordi jeg har lavt blodsukker. Nå bruker jeg hele dagen på å prøve å få i meg noe, forteller hun.

Siden prøvene i Longyearbyen ga så få svar, skal Silje Marie Våtvik utredes videre i Tromsø. Hun håper å bli innkalt denne uka eller neste.

– Hva tenker du i dag om at vaksinen ga slike bivirkninger?

– Det er pent lite å gjøre med det nå. Men man gjør seg selvfølgelig noen tanker. Det har vært mye snakk om at vaksinen ikke er testet nok ut, men den har vært gitt i andre land før Norge. Jeg vet at det på utenlandske nettsider har vært skrevet om tap av lukt og smak i forbindelse med vaksinen, så det er rart at man ikke har utredet det nærmere eller informert om det, svarer Våtvik.

Ikke alene

Da hun oppsøkte sykehuset, var det ingen som hadde hørt om noen lignende tilfeller. Nå har 79 personer innrapport samme bivirkning til Statens legemiddelverk. Der har de ingen forklaring på hvorfor noen har mistet smak og lukt etter influensavaksinen.

– Det var ukjent for oss på forhånd at tap av smak og luktesans kunne være en bivirkning. Det var ikke kjent, før de første meldingene kom i Norge, sier avdelingsoverlege ved Statens legemiddelverk, Steinar Madsen.

Han kan ikke forklare hvorfor noen får denne bivirkningen.

– Vi har ingen forklaring på hvorfor det skjer. Vi kan heller ikke si helt sikkert om det har en sammenheng med vaksinen. Det finnes andre forklaringer, som at man får en virusinfeksjon samtidig som man tar vaksinen, sier Madsen.

Vil bli bra igjen

– Hvor lenge må de som har fått denne bivirkningen regne med å være uten smaks- og luktesans?

– Det kan jeg ikke svare på. Jeg har snakket med én pasient som fortalte at hun ble bra igjen etter et par uker, svarer Madsen som forsikrer at de som opplever tap av smak og lukt vil bli bra igjen.

Risikogrupper får

Hittil har 552 personer vaksinert seg mot svineinfluensa i Longyearbyen. Sykehuset har denne uka fått opp ytterligere 500 doser av vaksinen. Av dem skal 100 til Barentsburg. Resten skal fordeles i Longyearbyen på barn og på voksne i risikogruppene som ikke hadde mulighet til å ta vaksinen sist.

– Jeg tror ikke det vil være nok vaksiner til andre voksne denne gangen, sier oversykepleier Aksel Bilicz ved Longyearbyen sykehus.

Barn under skolealder kan vaksineres på sykehuset i morgen, andre barn vil få tilbud om vaksine på skolen etter hvert.

Det er så langt påvist seks tilfeller av svineinfluensa på øya.

Batch of H1N1 vaccine pulled after bad reactions

CTV, 20 November 2009, 7:30 AM ET

https://web.archive.org/web/20091123092115/http://www.ctv.ca/servlet/ArticleNews/story/CTVNews/20091119/Flu_Reaction_091119/20091120?hub=Health

More than 100,000 doses of the H1N1 vaccine are being withdrawn across the country, after Manitoba health officials announced Thursday they'd noticed a higher-than-usual number of allergic reactions from one batch.

Vaccine manufacturer GlaxoSmithKline has asked several provinces to set aside the 170,000 doses from the questionable batch.

GSK say the batch recall is a precaution an they will investigate to see whether there is something wrong with the batch.

"GSK is taking this cautionary action because the Public Health Agency of Canada has received a higher than expected number of reports of anaphylaxis in this lot number compared to other lots," the company said in a written statement Thursday.

One or two allergic reactions are expected in a batch that size. But health officials recorded six severe allergic reactions and alerted GSK.

Dr. Joel Kettner, Manitoba's Chief Medical Officer of Health, urged people not to be alarmed, noting the anaphylaxis reactions were short-lived and all the patients recovered.

"We've been asked by the manufacturer GlaxoSmithKline not to use this vaccine at this time, pending further investigation," said Kettner at a press conference Thursday.

"We are being cautious and following the advice... to hold onto the remaining stock until we get further information."

About 1,500 doses of the vaccine were sent to Ontario, but officials say none were administered. Officials are now shelving them until the investigation is complete.

The Alberta government has stopped giving out doses from the same batch, although it says it has not seen a jump in allergic reactions.

Health officials say the batch being investigated is fairly small, so it should not have an impact on the overall supply.

Earlier this week, the country's chief public health officer, Dr. David Butler-Jones, noted that of the 6.6 million doses of H1N1 vaccine given so far to Canadians, there have been 36 serious adverse reactions reported.

Most involved allergic reactions that began within minutes of vaccination. All were treated promptly by medical people at the vaccination site.

Milder side effects, such as nausea, soreness, headaches and fever, have also been seen, which is not unexpected. Seasonal flu vaccines have been known to cause such reactions every year.

One person is believed to have died from an anaphylactic reaction following vaccination, but Butler-Jones stressed the death hasn't been conclusively linked to the flu shot.

"It's important to remember that just because a medical event follows vaccination, it may not have been caused by the vaccination; it may have been caused by other factors, as unfortunate events continue to occur with or without vaccine," he told a news conference Tuesday

Prof. Michel Chossudovsky

Canada: The Killer H1N1 Vaccine

Global Research, 20 November 2009
https://web.archive.org/web/20091204111422/http://www.globalresearch.ca/index.php?context=va&aid=16192

Of relevance to the current debate on the Covid19 vaccine, this article on the H1N1 vaccine was first published on November 20, 2009.

In 2009, the Canadian media provided us with detailed coverage on the adverse health impacts of the vaccine including two recorded deaths, one in Quebec and the other in Manitoba. What is the situation today with regard to media coverage? With some exceptions, the mainstream media is not informing the public. And reports on the adverse impacts of the covid-19 vaccine published by social media and the online independent media are the object of various forms of censorship.

***

"It is a serious thing [vaccine] that has the potential to kill" according to Dr. Neil Rau, an infectious disease expert, in a CTV interview, but do not worry: *"leading experts insist, the benefits of the H1N1 vaccine vastly outweigh the risks"* (Swine Flu Support Center, emphasis added)
=> https://thesurvivorsclub.org/support-center/health/general-health/swine-flu.html

A new development in the H1N1 Vaccine Saga is unfolding in Canada.

Whereas health officials are pushing for an acceleration of the vaccination program, there is evidence of so-called "unusual adverse reactions" including three recently recorded deaths directly resulting from the vaccine.

In the meantime, health authorities have called for the withdrawal of 170,000 (higher risk) doses of the vaccine produced by GlaxoSmithKline. The initiative, of which the importance is being downplayed, is said to have come from the manufacturer GlaxoSmithKline, which expressed concern on higher than normal adverse reactions to the vaccine.

"Canada's H1N1 flu vaccine manufacturer has asked the provinces to temporarily discontinue vaccinating Canadians from a lot of vaccine shipped in October due to a higher risk of adverse reactions, says a Manitoba health official.

Dr. Joel Kettner, Manitoba's chief public health officer, said Thursday that GlaxoSmithKline has asked that the October batch be taken out of circulation because it produced serious and immediate anaphylactic reactions in one out of 20,000 vaccinations, compared with one out of 100,000 in other shipments.

"We've been asked by the manufacturer GSK to not use this vaccine at this time pending further investigation," he said. (Winnipeg Free Press, 20 November 2009) =>
https://www.winnipegfreepress.com/arts-and-life/life/health/2009/11/20/manitoba-sees-second-death-this-season

The government is involved in a cover-up. The initial headlines stated "more than 100,000 doses", but then read on, the number is 170,000 doses.

The CTV report admits that "it is a serious thing, it has the potential to kill".

Too Late to Withdraw the 170,000 Defective Doses

The question is whether the doses can be withdrawn or whether they have already been used. The first news reports from Manitoba indicate that:

Of the 63,000 doses shipped [to Manitoba], only 630 remained unused by the four regional health authorities in Manitoba that received them. (Ibid)

This report would suggest that the risky GSK vaccine doses have already been used.

A subsequent report confirms that out of the 63,000 doses, 900 unused doses of the H1N1 vaccine were withdrawn by health authorities "after health authorities received word other vaccines from the same batch have been causing higher rates of allergic reactions than expected." (*Flu vaccine batch pulled in Manitoba*, Winnipeg Sun, 20 November 2009).

https://web.archive.org/web/20110513210649/http://www.winnipegsun.com/news/manitoba/2009/11/20/11824636-sun.html

The question is what happened to the remaining 62,100 doses of the higher risk vaccine batch, which were used to vaccinate people in Manitoba?

Has there been a followup regarding those people in Manitoba who received the higher risk H1N1 vaccine injection? What is the situation in other provinces in which the higher risk vaccine does were distributed?

Manitoba Health authorities casually confirm, in this regard, that "*most of the vaccine Manitoba received from the suspect lot had already been used* by the time the province received the alert on Wednesday" [November 18, 2009]. (Winnipeg Free Press, 20 November 2009) =>

https://www.winnipegfreepress.com/arts-and-life/life/health/2009/11/20/manitoba-sees-second-death-this-season

Manitoba and Quebec: Three deaths resulting from the H1N1 Vaccine

The news reports have highlighted deaths resulting from the H1N1 flu (often unconfirmed), while obfuscating several recorded deaths resulting directly from the vaccine. These vaccine related deaths are occurring at the very outset of the vaccination program,

According to CTV News, 20 November 2009) "The province is currently investigating *two deaths – both adults who died within seven days of getting the H1N1 shot*" (Family questions if H1N1 shot caused Manitoba woman's death, November 20, 2009). =>

https://web.archive.org/web/20091122094301/http://www.ctv.ca/servlet/ArticleNews/story/CTVNews/20091119/h1n1_death_091119/20091119?hub=Health

Manitoba officials acknowledge 69 "adverse events" after people received the swine flu shot, including the two deaths. (CBC.ca report, 17 November 2009) =>

https://web.archive.org/web/20091121104127/http://www.cbc.ca/canada/manitoba/story/2009/11/17/man-h1n1-adverse.html

However, unless the families speak out, the authorities will not provide details. CTV interviewed the family of one of the victims. No details on the other death in Manitoba are available:

"The family of a 38-year-old Manitoba woman who died five days after receiving the H1N1 vaccine are looking for answers as to why it happened.

Soo Lee Wong and her daughter, Angela Truong, both got the H1N1 shot on November 5th.

The family says Wong, who had diabetes, started getting sick a day after getting vaccinated and died a few days later.

Doctors told the family Wong died of a blood infection. More tests will be done to see if the vaccine played any role.

Wong's husband, Thoon Truong, is also caring for his seven-year-old daughter Angela, who has been in the hospital with a fever and swollen, painful legs.

He wants to know whether the two cases related to the vaccine or to something else.

The province is currently investigating two deaths — both adults who died within seven days of getting the H1N1 shot.

Although it's still early, Manitoba's chief medical officer of health Dr. Joel Kettner says immunizations were not likely the cause of the deaths. (CTV News | Family questions if H1N1 shot caused Manitoba woman's death, November 20, 2009)

https://web.archive.org/web/20091122094301/http://www.ctv.ca/servlet/ArticleNews/story/CTVNews/20091119/h1n1_death_091119/20091119?hub=Health

It should be noted that these two deaths in Manitoba may have been associated with the injection of the higher risk H1N1 vaccine doses, which health authorities had called for withdrawal.

Quebec: One Death

An 80-year-old Quebec man was reported dead after taking the H1N1 Swine Flu vaccination. Health officials have dismissed the case, "stating that it's too soon to link the death and vaccine." Quebec man dies after taking H1N1 vaccine, Digital Journal, 18 November 2009).

https://web.archive.org/web/20091124024520/http://www.digitaljournal.com/article/282399

The Quebec health authorities have refused to provide details: "Quebec's Director of Public Health Protection, Dr. Horacio Arruda, did not know why the man took the vaccine and that final test results, which are expected to come in December, will determine whether or not the man died from the vaccine.

Canada.com reports the man died in the last three weeks but provincial officials declined to reveal details, citing confidentiality concerns. Arruda has said that most allergic reactions occur right away, which is the reason why many patients are asked to stay in the centers, "We can't say there is a causal association between the death and the flu shot."

Nevertheless, Arruda is confident that the death will not discourage people from taking the vaccine but urged that serious reactions to the H1N1 shot are rare, "I understand that everyone is worried." (Quebec man dies after taking H1N1 vaccine, Digital Journal, 18 November 2009)

https://web.archive.org/web/20091124024520/http://www.digitaljournal.com/article/282399

The statements by senior health officials are notoriously ambiguous: while they concur that: "there is no evidence the vaccine is dangerous.", they nonetheless acknowledge the deaths resulting from the vaccine (Statement of Quebec's Director of Public Health Protection, Dr. Horacio Arruda, (The Canadian Press: Quebec health officials investigating possible death from H1N1 vaccine. November 18, 2009).

https://web.archive.org/web/20091123203241/http://www.google.com/hostednews/canadianpress/article/ALeqM5j79MYNA4k9_Q9BZRB-BdxX9i8k4g

POLITIKEN.DK

Overlæge: Vaccine virker trods dødsfald

Politiken, 20 November 2009, 18:47
https://web.archive.org/web/20091123144946/http://politiken.dk/indland/article840915.ece

Vaccinen mod svineinfluenza virker, selv om to mænd nu er døde efter at have fået indsprøjtningen.

Der er således ingen grund til panik eller at være urolig. Det slår Kåre Mølbak, overlæge ved Statens Serum Institut, fast.

I dag kom det frem, at to mænd nu er døde af svineinfluenzaen i Danmark. De var begge kronisk syge, og derfor i risikogruppen som myndighederne holder særligt øje med, lyder det fra Kåre Mølbak.

»Det her er ikke et udtryk for, at vaccinen ikke virker. Der er nogle i risikogrupperne, som bliver vaccineret og kan dø af svineinfluenza et par dage efter, inden vaccinen virker. Vi har altså at gøre med et tilfældigt sammentræf hos særligt sårbare personer«, siger Kåre Mølbak.

Tilfældigt sammentræf

Den ene mand er i begyndelsen af 60'erne og døde i forbindelse med en indlæggelse på Hvidovre Hospital. Den anden er i 30'erne og døde 12. november i sit hjem i København.

Kåre Mølbak understreger, at det er et sammentræf af uheldige omstændigheder.

»Men det kan altså ske, at vi ser en gentagelse, hvor en person i en risikogruppe dør, inden vaccinen kommer til at virke«, siger overlægen.

Grænsen er ikke klar

Han tilføjer, at danskere med symptomer på influenza ikke bliver vaccineret, men grænsen er ikke fuldstændig klar.

»Folk med høj feber bliver ikke vaccineret, men man kan godt gøre det, hvis den enkelte har lidt ondt i halsen eller en næse, der løber«, siger Kåre Mølbak.

Tre danskere er foreløbig døde af H1N1 - svineinfluenzaen. Ud over de to mænd døde en dansker i september i Norge.

THE FLU CASE

Two men in Denmark dies after getting the "swine flu" vaccine

The Flu Case, 21 November 2009, 17:52
https://web.archive.org/web/20091126013437/http://www.theflucase.com/index.php?option=com_content&view=article&id=2018%3Atwo-men-in-denmark-dies-after-getting-the-qswine-fluq-vaccine&catid=41%3Ahighlighted-news&Itemid=105&lang=en

According to Politiken, two men died shortly after having received the "swine flu" shot. Both was already in hospital and the official statements claim they died from "swine flu". Their death is also claimed to be "accidental" and there is officially "no link to the vaccination".

The Telegraph

Rebecca Smith

Swine flu: first death reported following vaccine

A person has died after being given the swine flu vaccine, it has emerged

The Telegraph, 22 November 2009, 9:00PM GMT
https://web.archive.org/web/20091125230817/http://www.telegraph.co.uk/health/healthnews/6615053/Swine-flu-first-death-reported-following-vaccine.html

Details of the person have not been released but officials said they had serious underlying medical conditions which are more likely to have been the cause of death than the vaccine.

The death was among over 1,300 suspected adverse reactions reported to the medicines regulator as part of surveillance of the vaccination programme.

Nine reports relate to suspected adverse reactions in pregnant women, who were between five months and seven months pregnant when given the jab. All suspected reactions affected the mother only and were not serious, the regulator said in a report.

The majority of the reports are about Pandemrix which is being used more widely than Celvapan, which is primarily for use in people will allergies to eggs.

The report from the Medicines and Healthcare products Regulatory Agency emphasised that the majority of people who have received the vaccines so far have had serious and chronic medical conditions 'over the next few months many of these patients will naturally suffer an exacerbation of their underlying illness including death'.

The document said: "Such events may occur shortly after vaccination and be reported as suspected adverse events. It is important to bear in mind that this temporal association does not in itself mean that the vaccine was responsible for the event and that this may be coincidental."

A report in The Lancet last month calculated the number of fatalities that would occur in Britain in people within six weeks of them being vaccinated as pure coincidence. Experts found that if ten million people were vaccinated there would be six sudden deaths.

The research also suggested that 397 per one million vaccinated pregnant women would be predicted to have a spontaneous abortion within one day of vaccination as a coincidence.

There are currently just over nine million people in priority groups being vaccinated who have long-term serious illnesses and pregnant women.

Sir Liam Donaldson, Chief Medical Officer, announced this week that once the priority groups were completed the vaccination programme would be extended to around three million healthy children aged between six months and five years.

The MHRA report said up until November 12th, there had been 25 reports of suspected reactions in children aged between 11 months and 16-years and the majority were not serious. Two children experienced seizures and one was diagnosed with reactive arthritis which can occur as a result of infection. A link with the vaccine has not been established.

The MHRA report said the majority of the suspected adverse reactions have been pain and swelling at the injection site, nausea and vomiting, muscle aches and headaches, which are all to be expected.

The report concluded that no serious safety issues have been identified from the UK to date and the benefit-risk balance for both vaccines remains positive.

Independently, the European medicines regulator has analysed new data on the vaccines and also concluded that they are safe.

The European Medicines agency report said about five million people in the EU have been vaccinated so far and reported effects 'have mainly been mild symptoms such as fever, nausea, headache, allergic reactions and injection site reactions'.

A small number of cases of Guillain-Barré syndrome and fetal death have been reported and that 'on the basis of the available information there is no evidence to link these to the vaccines'.

Guillain-Barré syndrome is a condition in which the body's immune system mistakenly attacks part of the nervous system and can be fatal in rare cases and has been linked to infection with influenza and to a vaccine given in America in 1976 although the evidence of a link with the jab was 'weak' experts have said.

The World Health Organisation said this week that 65 million doses of various swine flu vaccines have been administered so far with a good safety profile.

In a briefing Dr Marie-Paul Kieny, Director of the Initiative for Vaccine Research at the WHO, said there was no difference in the safety profiles of the different vaccines.

She said 30 deaths have been reported worldwide and none of them have been found to have been caused by the vaccine and 12 cases of Guillain-Barré syndrome have been reported and all have recovered well.

A spokesman for the Department of Health said: "There are no concerns about these reports – they show common and largely minor side effects like a sore arm, and are similar to the reports received elsewhere in Europe. Several million doses of Pandemrix are thought to have been issued globally.

"People who are offered the vaccine should have it to protect themselves."

Dr Philip Bryan, MHRA Expert Scientific Assessor said: "Most people receiving the vaccine have serious and/or chronic underlying medical conditions which put them at greater risk of developing serious complications of swine flu.

"This is why it is important for these people to be vaccinated as a priority. Over the next few months, many of these patients will naturally suffer an exacerbation of their underlying illness, including death.

"Such events may occur shortly after vaccination and be reported as suspected side effects. It is important to bear in mind that this temporal association does not in itself mean that the vaccine was responsible for the event and that this may be coincidental. Such reports are fully evaluated by the MHRA."

A spokesman for the Department of Health said: "There are no concerns about these reports – they show common and largely minor side effects like a sore arm, and are similar to the reports received elsewhere in Europe. Several million doses of Pandemrix are thought to have been issued globally.

"People who are offered the vaccine should have it to protect themselves."

Bivirkningene som overrasker
Har du opplevd å miste smaks- og luktesansen etter å ha tatt vaksinen mot svineinfluensa?
Statens legemiddelverk teller nå uventede bivirkninger

Netta Visen, 25 November 2009
https://www.nettavisen.no/nyheter/bivirkningene-som-overrasker/s/12-95-2765831

Statens legemiddelverk har så langt talt opp 276 rapporter om mistenkte bivirkninger etter vaksinering med Pandemrix. Noen av de mulige bivirkningene kommer overraskende på ekspertene, blant annet tre meldinger om folk som har mistet eller fått nedsatt smakssans. Nå skal dette undersøkes nærmere.

- Angrer på vaksinen

En 30 år gammel kvinne fra Svalbard fortalte til Nettavisen mandag at hun fem uker etter vaksinering fortsatt er uten smak- og luktesans. 48 år gamle Grethe Iversen fra Bjugn i Sør-Trøndelag sier til Nettavisen at hun ble dårlig etter vaksinering 27. oktober og også mistet smak og luktesansen.

- Jeg angrer på at jeg tok vaksinen. Hadde jeg visst det jeg gjør i dag, ville jeg ikke tatt den, sier hun.

- Lavt antall meldinger

Avdelingsoverlege Steinar Madsen i Statens legemiddelverk understreker at rundt en million nordmenn så langt har fått vaksinen og antallet rapporter om bivirkninger er lavt. I uka som gikk var det så langt kommet inn bivirkningsmeldinger fra 276 pasienter i alt.

- Det er et lavt tall. Vaksiner er generelt sett de tryggeste medisinene vi har. Vi tar likevel alle meldinger om bivirkninger på alvor, og rapporter om alvorlige bivirkninger blir undersøkt nærmere, sier Madsen.

Overrasket ekspertene

Han innrømmer at nedsatt smakssans er en bivirkning som ikke var forventet. I den samme gruppen med såkalt nevrologiske symptomer er det i alt talt opp 274 reaksjoner. For eksempel er det 17 meldinger om folk som har opplever metallsmak i munnen. Hodepine, nedsatt bevissthet, svimmelhet, bevissthetstap, nummenhet, lammelser og kramper er andre ting i denne gruppen. Antallet pasienter som har meldt om dette er langt lavere enn 274, siden mange har flere symptomer.

- Nei, det med nedsatt smakssans var ikke noe vi hadde regnet med. Det med metallsmak i munnen er ikke så uvanlig i forhold til legemidler. Det går som regel over i løpet av et til to døgn, men nedsatt smakssans var ikke noe vi forventet, sier han.

Prøver å finne en forklaring

Torsdag skal Statens legemiddelverk og Folkehelseinstituttet diskutere nettopp disse meldingene i et møte der de gjennomgår rapporterte bivirkninger så langt.

- Vi har ikke noen forklaring på hvorfor noen opplever dette. Vi må forsøke å finne ut om dette er en virkning av vaksinen eller om det er andre forhold hos pasienten som spiller inn, for eksempel at de er forkjølet. Forkjølelse kan typisk nedsette smak og luktesans, sier han.

Sykehus ville ikke rapportere

- *Kvinnen fra Sør-Trøndelag som mistet smak- og luktesansen etter vaksinering 27. oktober forteller at hun på sykehus fikk beskjed om at dette ikke skulle rapporteres inn som en mulig bivirkning. Ønsker dere å få inn slike rapporter*?

- Ja, leger skal rapportere inn på mistanke når det gjelder alvorlige eller nye og uventede bivirkninger.

- *Du sier at denne vaksinen er trygg, og svært mange nordmenn har valgt å ta den, men hvor sikker kan dere være på at det ikke dukker opp langtidsvirkninger dere ikke hadde regnet med?*

- Det er vi så sikre på som det går an. Vi har 50 års erfaring med influensavaksiner. Vi forventer ingen langtidsvirkninger, og nå har de også gått et par måneder siden de første vaksinene med Pandemrix ble satt i de landene som begynte først.

- *Forstår du likevel at det fortsatt er en del som er skeptiske til vaksinen*?

- Nei, jeg gjør egentlig ikke det. Jeg mener det ikke er noen grunn til å være mer skeptisk til denne vaksinen enn alle andre vaksiner. Vaksiner er generelt den tryggeste medisinen vi har.

Tror dødsfall er tilfeldigheter

Av 83 rapporter om mistenkte alvorlige bivirkninger så langt er det meldt inn åtte dødsfall som i tid skjedde få dager etter vaksinering. Statens legemiddelverk mener det ikke er noen sammenheng mellom dødsfallene og vaksinen, men skal undersøke tre av tilfellene nærmere før de trekker en endelig konklusjon. Det gjelder en kvinne på 89 år som døde tre dager etter vaksinering, en kvinne på 92 år som døde fem dager etter vaksinering og en mann på 85 år som døde tre dager etter vaksinering.

- I de fleste av disse tilfellene hadde pasientene også underliggende sykdommer, sier Madsen.

De foreløpige konklusjonene om tilfellene av spontanabort og fosterdød som er meldt inn er også at dette ikke skyldes vaksinen. Endelige konklusjoner vil helsemyndighetene likevel ikke trekke før de ser resultatene av obduksjonsrapportene.

- Når man vaksinerer mange personer over kort tid, vil det tilfeldigvis skje dødsfall som ikke har noen sammenheng med vaksinasjonen, sier Madsen.

Alle vaksinerte blir registrert

Folkehelseinstituttets Preben Aavitsland opplyser i en twittermelding at alle nordmenn som vaksinerer seg mot svineinfluensa blir registrert i helseregisteret PANVAK. – Registrering av vaksinerte er viktig for senere vurdering av effekt og bivirkninger av vaksinasjon, ifølge Aavitsland.

PreventDISEASE.com
Aiming Towards Better Health

79 have lost their ability to taste or smell after taking the H1N1 swine flu vaccine in Norway

Prevent Disease, 15 December 2009
https://web.archive.org/web/20100102174223/http://preventdisease.com/news/09/121509_79_Norway_lose_taste_smell_after_H1N1_vaccine.shtml

Silje Marie Vatvik lost both taste and smell after taking the vaccine against swine flu. She has been sick for several weeks.

"People do not understand what it means to have taste and odor. I do not taste the food and can therefore do not want to swallow it. It inhibits me socially because I can attend dinner functions, " says Silje Marie Vatvik.

The 30-year-old who lives in Longyearbyen, was one of the first to receive the vaccine against swine flu. She worked in the department responsible for preparedness initiatives at the airport and was expected by her employer to be vaccined the same day first vaccines arrived on October 21.

"Had I not been expected to take the vaccine, I would have at least had the option, and the first thing I asked about were the side effects," said Vatvik.

No response

Vatvik was not prepared for was to come after the vaccination, losing both her ability to taste and smell. She has not recovered these senses since taking the vaccine. The hospital administered many tests but the 30-year old has not responded to any of them.

"They kept all options open since it could have been a coincidence and nothing to do with the vaccine. But it was ultimately the one cause that remained," she says.

Vatvik is on sick leave indefinitely due to the illness. "I think about food all the time, have little energy and I'm irritable because I have low blood sugar," she says.

"There has been much talk about the vaccine not being tested, but it has been accepted in other countries before Norway. I know that foreign websites have been written about the loss of smell and taste associated with the vaccine, so it is strange that they were not more informed about it," said Vatvik.

When she went to the hospital, no one had heard of any similar cases. Now 79 people are suffering the same side effects notes the Norwegian Medicines Agency. They have no explanation for why some have lost their taste and smell after flu vaccine.

"It was unknown to us in advance that the loss of taste and sense of smell could be a side effect," said a spokesman from the Norwegian Medicines Agency, Steinar Madsen.

Madsen could not address why some patients suffer from the side effect. "We have no explanation for why it happens. We can not say for sure whether it has a relationship with the vaccine. There are other explanations, like that you get a viral infection while taking the vaccine," says Madsen.

When asked how long the patients it will take patients to recover, Madsen said, "I can not answer. I have talked to one patient who told me that she was well again after a couple of weeks."

SUOMI 24

Rokotehaitat Antti Heikkilälle!

Suomi 24, 23 November 2009, 10:39:42
https://keskustelu.suomi24.fi/t/8642245/rokotehaitat-antti-heikkilalle!

Eli hän on kirurgi, ortopedi ja traumatologian erikoislääkäri. Haluaa puolustaa kansalaisia, meiltä on pimitetty paljon.

Hänen uusi bloginsa täällä, siellä osoite mihin voi lähettää rokotteiden haitat!
…
"Ruotsissakin professori Tore Schersten ihmettelee, ettei rokotusten haitoista puhuta julkisuudessa.

Sitä minäkin olen ihmetellyt tässä ns. ”vapaassa” demokratiassa. Olen saanut paljon postia ihmisiltä, jotka ovat kertoneet hurjistakin rokotuksen jälkeisistä reaktioista. Jotta asia pääsisi esille edes jotain kautta, pyydän ihmisiä lähettämään tietoja rokotuskokemuksistaan minulle osoitteeseen Haluan varmistua, että kysymyksessä on todellinen henkilö ja että tarina on tosi. Siksi viestissä pitää olla kirjoittajan nimi ja puhelinnumero. Henkilöllisyys jää minun tietooni, ja tarinat julkaistaan sivustollani nimimerkillä. Mielestäni tässä tilanteessa kokemusten jakaminen on äärimmäisen tärkeää, ettei totuus unohtuisi."

"In Sweden professor Tore Schersten is amazed by why there is no public discussion of the vaccine disadvantages. This is something I have also been amazed by in this so called "free" democracy. I have received lot of messages from people telling me about even frantic post-vaccine reactions. In order to get this all published even in some way, I am asking people to send me their experiences of vaccination to me to address. I want to be sure that the sender is a real person and the story is true. That's why there has to be a real name and an address in these messages. The identity will remain only in my knowledge and the stories will be published with an alias name. I think that in these current circumstances sharing experiences is utmost important so that the truth wouldn't fade away."

THE FLU CASE

Finnish doctor compiles list of Swine Flu vaccine damage as authorities do nothing

The Flu Case, 8 December 2009 15:35
https://web.archive.org/web/20100102023738/http://theflucase.com/index.php?option=com_content&view=article&id=2214%3Afinnish-doctor-compiles-list-of-swine-flu-damage-as-authorities-do-nothing&catid=1%3Alatest-news&Itemid=64&lang=en

A Finnish medical doctor Antti Heikkilä has started collecting reports of side effects suffered by people who took the swine flu jab as authorities – many of whose leading members have proven financial links to big pharma – play down the damage.

Heikkila reports 29 separate confirmed cases concerning about 100 people suffering a range of symptoms from a little pain or ache, to flu like symptoms, fluid in lungs, hallucinations after Tamiflu treatment as well as death and miscarriages.

One nurse (midwife) reported a night when there were no other cases than miscarriages. Also, one child was given the jab even though parents did not give permission.

Heikkila started collecting reports after 23rd of November when about 1 million people in Finland were vaccinated.

There needs to be a criminal investigation into the national and international authorities such as the EMEA, which is two thirds funded by pharmaceutical companies, and whether they are systematically suppressing evidence of the damage and death caused by these vaccines for profit.

PHYS ORG

Six bad reactions to swine flu vaccine in Canada: official

Phys Org, 24 November 2009.
https://web.archive.org/web/20150719122159/http://phys.org/news/2009-11-bad-reactions-swine-flu-vaccine.html

Six severe allergic reactions to swine flu vaccinations have been observed in Canada, health authorities said Tuesday, adding that all of the individuals are feeling better.

All of the cases of anaphylactic shock were linked to a single batch or 172,000 doses of Aprepanrix vaccines made by GlaxoSmithKline (GSK) distributed starting November 2, said Caroline Grondin, a spokeswoman for Canada's health ministry.

Distribution of the batch to six provinces – British Columbia, Alberta, Saskatchewan, Manitoba, Ontario and Prince Edward Island – was halted, she said.

But she could not say how many doses had been used before distribution was suspended.

The health ministry believes the number of adverse reactions is abnormally high and has asked officials to investigate. One allergic reaction in 100,000 doses is the currently accepted norm.

Anaphylactic shock is a severe, rapid and sometimes fatal allergic reaction to a foreign substance such as a vaccine, shellfish or insect venom. Symptoms include difficulty breathing and a sudden drop in blood pressure.

It is a serious medical issue, said Grondin, but anyone who received the vaccines and did not have a reaction should not worry.

The A(H1N1) vaccine is safe and effective, she insisted. "The fact that we've uncovered problem with a specific batch shows that our monitoring system works," Grondin told AFP.

The World Health Organization (WHO), which first alerted health authorities of potential problems with this batch of vaccines, has not changed its recommendations regarding swine flu vaccines.

These remain, according to the WHO, the most effective way to fight the virus, which has killed some 6,750 people worldwide since it first appeared in March.

The Sydney Morning Herald

Canada notes swine flu vaccine allergies

The Sydney Morning Herald, 24 November 2009, 11.12 pm
https://www.smh.com.au/world/canada-notes-swine-flu-vaccine-allergies-20091125-jjj8.html

An unusual number of severe allergic reactions to swine flu vaccinations have been recorded in Canada, where a batch of the vaccine from GlaxoSmithKline has been recalled, the WHO said on Tuesday.

"An unusual number of severe allergies to the vaccine have been detected in Canada," World Health Organisation spokesman Thomas Abraham told AFP.

"The Canadian authorities are conducting the appropriate investigations on the vaccines", he said, and had recalled a batch of vaccine from GSK.

"We need to understand what happened in Canada," he said.

ALARABIYA news

Severe reactions to swine flu vaccine in Canada
Vaccine reported to have adverse side effects, 30 deaths

Al Arabiya, 24 November 2009
https://english.alarabiya.net/articles/2009%2F11%2F24%2F92283

DUBAI (Al Arabiya)

Fresh off the heels of an announcement that at least 30 had died after taking the swine flu vaccination, Canadian authorities were told Tuesday to pull a batch of the H1N1 vaccine due to "severe allergic" reactions.

According to the World Health Organization (WHO) an unusual number of severe allergic reactions to the vaccination have been recorded in Canada, prompting authorities to recall a batch of the vaccine from GlaxoSmithKline (GSK).

The Canadian authorities are conducting the appropriate investigations on the vaccines" and recalled a batch of vaccine from GSK," WHO spokesman Thomas Abraham told AFP.

We need to understand what happened in Canada, he added.

Reactions in heart and lungs

GlaxoSmithKline spokeswoman Gwenan White said that the affected doses of its Aprepanrix vaccine had caused reactions to the heart and lungs.

White added that some 172,000 doses are involved, although she declined to reveal how many of those had already been used.

GlaxoSmithKline have asked Canadian medical authorities to stop administering vaccines from the affected batch, White said, adding the company's investigations were ongoing.

WHO spokesman Thomas Abraham said that the WHO had not changed its recommendations regarding swine flu vaccines despite several reports of adverse side effects, including at least 30 deaths.

Vaccine deaths

Last week, the WHO said checks on many of the 30 deaths recorded following mass pandemic flu vaccinations had so far ruled out a direct link to the vaccines.

Britain's Daily Mail reported on Saturday that at least one person had died after being given the Pandemrix vaccination and a further 1,329 suffering adverse reactions in just four weeks.

Some of the most severe reactions to the injections include pain and swelling at the injection site and vomitting, dizziness and fever, the paper reported, adding there were also "two cases of anaphylactic shock, one child experienced arthritis and two had seizures

TIMES OF MALTA

Severe reactions to swine flu vaccine in Canada – WHO

Times of Malta, November 24, 2009
https://timesofmalta.com/articles/view/severe-reactions-to-swine-flu-vaccine-in-canada-who.283247

An unusual number of severe allergic reactions to swine flu vaccinations have been recorded in Canada, where a batch of the vaccine from GlaxoSmithKline (GSK) has been recalled, the WHO said yesterday.

"An unusual number of severe allergies to the vaccine have been detected in Canada," World Health Organisation spokesman Thomas Abraham said.

"The Canadian authorities are conducting the appropriate investigations on the vaccines" and "recalled a batch of vaccine from GSK."

"We need to understand what happened in Canada," he added.

GlaxoSmithKline spokewoman Gwenan White said that the affected doses of its Aprepanrix vaccine had caused reactions to the heart and lungs.

Ms White added that some 172,000 doses are involved, although she declined to reveal how many of those had already been used.

GlaxoSmithKline have asked Canadian medical authorities to stop administering vaccines from the affected batch, Ms White said, adding the company's investigations were ongoing.

WHO spokesman Thomas Abraham said that the WHO had not changed its recommendations regarding swine flu vaccines.

Last week, the WHO said checks on many of the 30 deaths recorded following mass pandemic flu vaccinations had so far ruled out a direct link to the vaccines.

The fatalities made up a minute fraction of at least 65 million doses of swine flu vaccines which have been administered, said the WHO, citing data from 16 countries.

For every 10,000 doses of vaccines administered, only one report of adverse effect had been logged.

Of every 100 reports of adverse effects, five are serious cases such as death, the WHO said.

More than 6,750 people have died worldwide since the virus appeared in April, according to WHO data.

Ukraine and World Pneumonic Plague Information

WHO acknowledges Canada's Side Effects from Recalled Vaccine

Ukraine and World Pneumonic Plague, 24 November 2009, 10:20 am
http://ukraineplague.blogspot.com/search?updated-max=2009-11-27T07:51:00-05:00&max-results=10&start=118&by-date=false

What are the Real numbers I wonder, if the WHO is acknowledging problems with the Swine Flu vaccine. Considering they have thrown out deaths and adverse side effects from the vaccine as merely coincidences previously, what have been the side effects and what are the REAL numbers in Canada, for them to make this statement?

There has to be some very profound numbers involved and I would say many more than what they are admitting to. That is my opinion, due to their previous statements as posted on this site.

Of every 100 reports of adverse effects, five are serious cases such as death, according to the WHO.

Judicial Watch®
Because no one is above the law

Over 1000 Adverse Reactions to H1N1 Vaccine Since October

Judicial Watch, 24 November 2009, 4:31 pm
https://web.archive.org/web/20100103141143/https://www.judicialwatch.org/foiablog/2009/nov/over-1000-adverse-reactions-h1n1-vaccine-october

In recent months, H1N1, or swine flu, has been spreading allover the globe, raising concern and alarm. First detected in March 2009, H1N1 is already responsible for over 1,000 deaths in the U.S. alone. Worldwide, H1N1 flu has become a globalproblem, as an outbreak map created by the New England Journal of Medicine shows. While most common in the U.S. and Europe, H1N1 is also affecting much of Asia and parts of Africa. One of the biggest problems concerning H1N1 has been the lack of vaccines. Although the U.S. originally estimated that approximately 120 million doses of the vaccine would be available by mid-October, in the beginning of November only 11 million had been produced. But while the vaccine may help protect against swine flu, reports from the Centers for Disease Control suggest that the vaccine has problems of its own.

Since the vaccine began being administered in early October, there have been almost two thousand adverse events reported to the Centers for Disease Control vaccine reporting system, VAERS. Judicial Watch used the Freedom of Information Act to request copies of the VAERS. From October 1 – November 4th, there were 1,112 adverse reactions reported. The most common side effects were generally not serious and included fever (present in 240 cases) and nausea (present in 112 cases). However, there were also cases of serious and life threatening reactions. In total, 38 cases were classified as serious, and twelve were considered life threatening. There were also six people who died after receiving the vaccine, although at this time it is unknown whether the vaccine caused the deaths.

Many of the adverse reactions affected young children,including an eight year old who suffered "chills, increased [heart rate],lethargy and altered mental status…cough, nasal congestion, fever, diarrhea, sore throat, disoriented and lethargic" (ID: 362672). His condition was considered serious and he was hospitalized. Another child was hospitalized when he experienced seizures and convulsions immediately after receiving the vaccine (ID: 362926). Less than one day after vaccination, a 5 year old boy visited the ER with an aggravated "croup sounding cough." He "could not breathe…even tried crying – he was not able to get air in his lungs…started turning blue/gray" (ID: 361270). Another five year old developed "life threatening" symptoms within one day of receiving the vaccine, including a cough, hoarseness, and a high fever (ID: 362913).

A one and a half year old baby with no pre-existing conditions was hospitalized three days after receiving the vaccine with a long list of symptoms including: "Cough, Crying, Diarrhea, Dyskinesia, Irritability, Malaise, Movement disorder, Muscle spasms, Muscle twitching, Pyrexia, Pyuria, Respiratory tract congestion, Rhinorrhoea, Screaming" (ID: 362196). Similarly, another one-year-old infant wasadmitted to the hospital three days after receiving the vaccine. He had a high fever and began sufferingseizures. His status was classified as life threatening, and he spent 10 days in the hospital (ID: 364197).

The vaccine may also be harmful during pregnancy. In one VAERS report, a woman who was eight months pregnant with healthy prenatal exams received the vaccine. Four days later, she complained

of nausea and feeling warm. At the hospital, it was discovered that the baby had died. While the cause of death was unknown, the ultrasound revealed that there was "no amniotic fluid around the baby" (ID: 36299).

There was no overall similarity in serious cases, but the more common side effects included severe shortness of breathe and seizures. A 55 year-old man suffered a life threatening reaction "immediately after H1N1 vaccine…[patient] reported not feeling well, could not breathe, obvious respiratory distress, weakness, and cyanosis, elevated heart rate" (ID: 362087). Another man "developed headache that progressively got worse with facial pain" one day after receiving the H1N1 vaccine. After being admitted into the hospital, he had a seizure (ID: 363685). In an extremely serious case, A 35 year old patient with no previous medical conditions died three days after receiving the H1N1 vaccine, after being sent to the ER for "nausea, vomiting, chills, stomach cramping, diarrhea, tachypnea, hypotension, and diaphoresis." The cause of death was "due to septic shock" and asplenia, a condition that occurs when the spleen is not functioning properly (ID: 362855).

VAERS reports also suggest that in some cases, the vaccine could be causing H1N1 flu. One woman was given the H1N1 vaccine and less than three days later she was sent to the emergency room and hospitalized, "presumed H1N1 positive, from the H1N1 vaccine." Her condition was classified as life threatening (ID: 36285). A man who had received the vaccine went to a clinic and was diagnosed as having "more than likely – H1N1 as a result of the live virus vaccine" (ID: 361344). Another woman was hospitalized two days after vaccination, with "H1N1 suspected."

The Department of Health and Human Services continues to monitor the vaccine but has concluded that the H1N1 vaccine is safe**.** Others, however, have raised questions. Barbara Loe Fischer of the National Vaccine Information Center questioned both the necessity of the vaccine and the seriousness of H1N1 itself**.** Fisher stated that the vaccine was overhyped, and that there was "an unprecedented campaign by the federal health officials for us to take this very seriously when the evidence is that this is not anymore serious than the season influenza." Most people conclude that the H1N1 vaccine has the same safety rate as regular flu vaccines. Still, caution is necessary, especially in light of the reactions to the vaccine. In order to aid the public in their decisions regarding the vaccine, Judicial Watch has included all VAERS reports from October through November 7, 2009 below, and will be requesting updated reports as necessary.

CBSNEWS

Dangerous Batch of H1N1 Vaccine Found

CBS News, November 24, 2009 / 7:46 AM EST / AP EST / AP
https://www.cbsnews.com/news/dangerous-batch-of-h1n1-vaccine-found/

Canadian doctors have been advised not to use a batch of 170,000 doses of swine flu vaccine while authorities investigate reports of allergic reactions among recipients, drug maker GlaxoSmithKline PLC said Tuesday.

Authorities routinely monitor vaccines for any signals of problems, such as the allergic reactions that do occur, rarely, every year.

Company spokeswoman Gwenan White said that GlaxoSmithKline advised medical staff in Canada last week to refrain from using one batch of the vaccine while they look into reports that that it might have caused more allergic reactions than normal.

"One batch has seen a slightly increased rate of anaphylaxis," she said. Anaphylaxis is life-threatening type of allergic shock.

Six people in Canada had suffered an allergic reaction, said Tim Vail, the spokesman for Canada's health minister. The batch contained about 170,000 doses. It was not immediately clear how many had been administered, although Vail said the majority had been.

GlaxoSmithKline said it has distributed a total of 7.5 million doses of the vaccine across Canada.

"We're not seeing any thing wild or spooky or crazy about our vaccine at all," Vail said, arguing it may have been a statistical anomaly that the reactions occurred.

The vaccine chief of the World Health Organization, Marie Paule Kieny, said Monday that the number of people who went into anaphylactic shock after getting the vaccine in Canada was "a bit higher than normal" but that the numbers were still small. She said Canadian authorities are investigating the components of the vaccine to see if there might be a problem.

She said the problem has so far only been detected with one lot of the vaccine and that they haven't seen evidence of a higher rate of side effects with other lots.

GlaxoSmithKline, the world's second largest drug maker by revenue, is only investigating the one batch of its swine flu vaccine in Canada. White said no other doses of its swine flu vaccine around the world are affected.

White said London-based GlaxoSmithKline wrote to Canadian health care professionals advising them to stop using the batch on Nov. 18.

Canada is honoring the company's request, but urging people not to be alarmed. Dr. Joel Kettner, Manitoba's chief medical officer of health, said that allergic reactions sometimes occur shortly after inoculations, but haven't lasted long and have not led to long-term health problems.

The provincial Alberta government was also holding back the vaccine, although it had not seen a jump in reactions.

Influenza A (H1N1): Faulty swine flu vaccine withdrawn in Canada

EuroNews, 24 November 2009, 19:11 CET
https://web.archive.org/web/20091127053540/http://www.euronews.net/2009/11/24/faulty-swine-flu-vaccine-withdrawn-in-canada/

British drugs giant GlaxoSmithKline has has warned the Canadian medical authorities that a batch of its anti-H1N1 vaccine can trigger potentially dangerous allergic reactions. The Canadians have withdrawn the batch from use and are testing it after it produced a range of serious reactions, notably in the heart and lungs. The recall affects 172,000 dises of the Arepanrix vaccine.

"We've been asked by the manufacturer GSK not to use this vaccine at this time pending further investigation," said Manitoba chief medical officer Joel Kettner.

Thirty-six Canadians, including one little boy whose face swelled up like a balloon, suffered severe allergic reactions after vaccination. 200 others died.

"It is a serious thing that has the potential to kill – but fortunately seems to be relatively rare," said Dr Neil Rau, an infectious disease specialist.

Canada has been particularly badly hit by the flu virus, and has vaccinated around a fifth of its population, or nearly seven million people, already. GSK has sold seven point five million doses to Canada.

Le Monde

Inquiétude au Canada après une série de réactions allergiques au Vaccin contre la Grippe A

Le Monde // AFP, 24 Novembre 2009, 14h31

https://www.lemonde.fr/epidemie-grippe-a/article/2009/11/24/inquietude-au-canada-apres-une-serie-de-reactions-allergiques-au-vaccin-contre-la-grippe-a_1271458_1225408.html

Un lot de vaccin du groupe pharmaceutique GlaxoSmithKline (GSK) a été rappelé, indique l'Organisation mondiale de la santé.

Alors que les campagnes de vaccination ont démarré dans une quarantaine de pays, un nombre inhabituel de réactions allergiques "graves" au vaccin contre le virus grippal H1N1 a été enregistré récemment au Canada où un lot du groupe pharmaceutique GlaxoSmithKline (GSK) a été rappelé, indique l'Organisation mondiale de la santé.

"Les autorités canadiennes mènent les recherches" nécessaires pour établir les causes de ces allergies, indique un porte-parole de l'OMS, Thomas Abraham. Il a assuré que l'OMS ne changeait pas dans l'état actuel ses recommandations concernant les vaccinations à grande échelle, qui restent selon l'organisation le moyen le plus efficace pour lutter contre un virus jugé "vicieux". "Nous devons d'abord comprendre ce qui s'est passé au Canada", a insisté le porte-parole.

Le Canada est particulièrement touché par la première pandémie de grippe atypique du siècle qui a tué plus de 6 750 personnes dans le monde depuis son apparition au printemps. Le pays où, selon les dernières données de l'OMS, "la transmission grippale continue de s'intensifier sans montrer clairement qu'elle a atteint un pic", dénombrait près de 200 morts le 17 novembre. A cette date, les autorités sanitaires faisaient également état de 36 cas de réactions graves sur les 6,6 millions de personnes vaccinées, représentant environ un cinquième de la population du pays.

L'OMS est montée au créneau à plusieurs reprises pour contrer une suspicion répandue contre le vaccin H1N1 produit à vive allure sur ses ordres.

L'OMS a répété vendredi que les vaccins restaient "efficaces" et ce malgré des cas de mutations du virus enregistrés notamment en Norvège. Quant à la trentaine de décès signalés dans le cadre des vaccinations à grande échelle, rien ne permet, selon l'organisation, d'établir, pour le moment, un lien avec les vaccins. Un cas d'effet secondaire indésirable est rapporté pour 10 000 doses de vaccin administrées. Sur 100 effets secondaires indésirables, cinq sont sérieux, y compris un décès, avait alors expliqué une responsable de l'organisation onusienne.

Canada notes swine flu vaccine allergies

The Sydney Morning Herald, 24 November 2009, 11:43 pm.
https://www.smh.com.au/world/severe-reactions-to-swine-flu-vaccine-in-canada-20091124-jj80.html

An unusual number of severe allergic reactions to swine flu vaccinations have been recorded in Canada, where a batch of the vaccine from GlaxoSmithKline (GSK) has been recalled, the WHO said on Tuesday.

"An unusual number of severe allergies to the vaccine have been detected in Canada," World Health Organisation spokesman Thomas Abraham told AFP.

"The Canadian authorities are conducting the appropriate investigations on the vaccines" and "recalled a batch of vaccine from GSK." "We need to understand what happened in Canada," he added.

GlaxoSmithKline spokeswoman Gwenan White told AFP that the affected doses of its Aprepanrix vaccine had caused reactions to the heart and lungs. White added that some 172,000 doses are involved, although she declined to reveal how many of those had already been used. GlaxoSmithKline have asked Canadian medical authorities to stop administering vaccines from the affected batch, White said, adding the company's investigations were ongoing.

WHO spokesman Thomas Abraham said that the WHO had not changed its recommendations regarding swine flu vaccines. Last week, the WHO said checks on many of the 30 deaths recorded following mass pandemic flu vaccinations had so far ruled out a direct link to the vaccines.

The fatalities made up a minute fraction of at least 65 million doses of swine flu vaccines which have been administered, said the WHO, citing data from 16 countries.

For every 10,000 doses of vaccines administered, only one report of adverse effect had been logged. Of every 100 reports of adverse effects, five are serious cases such as death, the WHO said.

More than 6,750 people have died worldwide since the virus appeared in April, according to WHO data.

Reactions to Glaxo Flu Vaccine under Investigation in Canada

Bloomberg, 25/27 November 2009
http://www.bloomberg.com/apps/news?pid=20601082&sid=aUle5CWoYOp4
https://web.archive.org/web/20100102033734/http://theflucase.com/index.php?option=com_content&view=article&id=2089%3Areactions-to-glaxo-flu-vaccine-under-investigation-in-canada-&catid=1%3Alatest-news&Itemid=64&lang=en

Nov. 25 (Bloomberg) – Canada is still investigating an unusually high rate of a side effect known as anaphylaxis from a batch of GlaxoSmithKline Plc's swine flu vaccine, health officials said today.

Anaphylaxis occurred at a rate of about 4 per 100,000 shots in one lot of 172,000 doses of the vaccine, David Butler-Jones, Canada's chief public health officer, said at an Ottawa news conference. Typically, about 1 person in 100,000 will suffer such a reaction. Anaphylaxis is an acute allergic reaction that includes swollen tongues, throats and respiratory distress.

Glaxo, the sole supplier of swine flu shots to Canada, has shipped 7.5 million doses of the Arepanrix vaccine to the country, the company said this week. For all batches, the rate of side effects is 0.32 per 100,000, health officials said today.

The higher rate from one batch may be a statistical anomaly, Butler-Jones said. About 15,000 shots from the batch that still haven't been used are being held back while investigators look into the matter, officials said. There were no obvious glitches in the manufacturing process, Butler-Jones said.

"What they're looking at is whether or not there was something else, whether it was something to do with when it was shipped," he said. "It gives us cause to wonder whether there's something wrong or it may just be the odds."

The reactions are not related to the adjuvant that is added to boost the vaccine's potency, Butler-Jones said.

Investigation Ongoing

Gwenan White, a spokeswoman for London-based Glaxo, said the company is working with Canadian officials.

"Normally in this type of situation we would get a vial or something from that batch and we would test it, but that's done in combination with other elements of the investigation," she said. "The investigation is ongoing."

About 65 million people worldwide have been vaccinated with swine flu vaccine, the World Health Organization said in a statement last week. Evidence so far indicates that shots for the pandemic H1N1 influenza are as safe as those for seasonal flu, the Geneva-based United Nations health agency said.

Nearly 80 million doses of vaccine have been distributed in 40 countries with pandemic immunization campaigns under way, the agency said. Other companies manufacturing vaccine include Novartis AG, Baxter International Inc., CSL Ltd., Sanofi-Aventis SA and AstraZeneca Plc.

South Korea said today it no longer plans to buy GlaxoSmithKline Plc's swine flu vaccine. The decision isn't related to the side effects reported in Canada, Oh Sung Il, a spokesman for the Ministry for Health, Welfare and Family Affairs, said in a telephone interview today, declining to give details.

In August, South Korea said it planned to buy 10 million doses of swine flu vaccine by the end of this year. Green Cross Corp., a domestic vaccine developer, would supply 7 million doses and Glaxo the remainder, the government said at the time.

Public health reports 24 cases of H1N1 flu shot reaction

The Star (Toronto), 25 November 2009
https://www.thestar.com/life/health-wellness/public-health-reports-24-cases-of-h1n1-flu-shot-reaction/article_9f4dfcef-0e23-5167-bf69-79f9faca8e61.html

Toronto – There have been 24 confirmed cases of a type of severe allergic reaction called anaphylaxis in Canadians who have received an H1N1 flu shot, including one person who died after getting vaccinated, the head of the Public Health Agency of Canada said Wednesday.

Dr. David Butler-Jones said the person who died - identified in the media as a Quebec man in his 80s - met the criteria for having an anaphylactic reaction. But he said it's still not clear whether that or other health problems caused the death.

"There were a number of other situations. So exactly what the ultimate cause was or what the issues are, that will take some time, I understand, to investigate," said Butler-Jones.

Anaphylaxis is a severe allergic reaction that can cause a person's airways to close up. It can be fatal and must be treated quickly with adrenaline, generally administered via the EpiPen devices carried by people with severe food or insect sting allergies.

Butler-Jones disclosed the information in Ottawa during a news conference at which federal health officials revealed flu activity appears to be levelling off in some parts of the country.

They did not say where, though Butler-Jones did mention there has been a decline in new hospitalizations in British Columbia, which was at the forefront of the current wave of activity.

However, Butler-Jones warned a good chunk of the Canadian population is likely still susceptible to the virus. He estimated between five and 10 per cent of people have probably been ill and about 25 per cent have been vaccinated.

"Influenza remains an unpredictable disease," he said.

"And reaching the plateau of the second wave in some communities does not mean that the pandemic is over. There is still the other side of the peak. And there remain millions of infections to be prevented."

Officials hope to persuade millions more of those folks to get vaccinated, especially now that vaccine production is expected to more than keep pace with demand.

Health Minister Leona Aglukkaq said she will be vaccinated within the next few days. She noted that by the end of this week a total of more than 15 million doses of vaccine will have been shipped to the provinces and territories.

That's almost enough for half the country's population, nearly the proportion of Canadians who've indicated in the most recent public opinion polls that they intend to get vaccinated.

Butler-Jones said despite the signals there may be a levelling off underway, flu activity remains four to seven times higher than is normally seen at this time of year. That's not altogether surprising - there generally isn't much flu activity at this point in the year.

For the week ending Nov. 14 there were 1,674 new hospitalizations, 261 ICU admissions and 84 deaths, he said. As of Tuesday, there had been 279 laboratory confirmed deaths in Canada caused by this virus.

On the issue of serious adverse reactions to the H1N1 vaccine, Butler-Jones said the rate of anaphylactic events was about 0.32 cases for every 100,000 doses of vaccine delivered - a figure that's within the norm for mass vaccination efforts.

And an official of the Centers for Disease Control said the U.S. agency has looked at reports of severe allergic reactions after H1N1 shots and isn't seeing anything abnormal.

"We've also looked in a little more detail at severe allergic reactions, and, again, those are not showing up more commonly than we would expect," said Dr. Anne Schuchat, director of the CDC's national center for immunization and respiratory diseases.

Attention was drawn to the issue of anaphylaxis last week when vaccine maker GlaxoSmithKline told provinces to stop using vaccine from a batch of 172,000 doses that was sent out last month. The halt-use order was issued because six people vaccinated from that batch developed anaphylaxis - a higher than expected number of such cases.

All but 15,000 doses of the vaccine had been used by the time the halt-use order was issued, said Dr. Danielle Grondin, assistant deputy minister of the public health agency.

But confirmed cases of anaphylaxis have been seen with other batches as well. And some possible cases may still be under investigation.

Ursula Fournier's son Max is one. The Halifax mother said Wednesday she's still waiting to hear if the reaction Max, 4 1/2, suffered when he got his shot on Nov. 3 was anaphylaxis.

Almost immediately after getting the shot, Max went limp, Fournier said. His blood pressure dropped and his breathing got "really laboured and loud," she said.

Staff of the clinic quickly used an EpiPen to revive the boy, who was then taken to the local children's hospital, IWK Health Centre, where he was kept under observation for six hours.

Fournier was told Max's doctor would be contacted and the boy would be referred to an allergy specialist. But she'd like to know if her son had an anaphylactic reaction.

"I would think as his parent it's my responsibility to get to the bottom of it," said Fournier, who expressed frustration at the lack of information.

Vaccinet stoppas tillfälligt i Kanada

Aftonbladet, 25 November 2009
https://web.archive.org/web/20091126211338/http://www.aftonbladet.se/nyheter/svininfluensan/article6182086.ab

Har gett flera patienter allvarliga biverkningar.

Kanadensiska läkare stoppar tillfälligt ett parti av svininfluensavaccinet på uppmaning av leverantören Glaxo Smith Kline.

Vaccinet har gett flera patienter allvarliga biverkningar.

– Men det här handlar om en specifik tillverkningssats, så det finns inga skäl att ändra rekommendationerna i Sverige, säger Charlotta Bergquist, klinisk utredare på Läkemedelsverket.

Sammanlagt stoppas 170 000 doser av vaccinet i Kanada.

En av 20 000 personer som har vaccinerats av det aktuella vaccinet har fått andningssvårigheter, förhöjd hjärtrytm och hudutslag.

Det är fem gånger så många som väntat. Ingen av patienterna ska dock ha fått långvariga problem av vaccinet.

Rodnad och smärta

Leverantören Glaxo Smith Kline, som även levererar vaccin till Sverige, säger sig inte veta vad de många biverkningarna beror på.

Men företaget uppmanar läkare i Kanada att inte använda vaccin från den aktuella leveransen. Tillsammans med kanadensiska myndigheter utreder läkemedelsföretaget nu de många biverkningsfallen, berättar den svenska talespersonen för företaget för Aftonbladet.

På Läkemedelsverket följer man noga rapporterna kring svininfluensavaccinet. Men det som hänt i Kanada är inget skäl för att ändra rekommendationerna i Sverige.

– Det vaccin som används i Kanada tillverkas även i Kanada. Det har en annan sammansättning som inte är helt identiskt med som det som används i Sverige. Och just det vaccin som nu stoppats var knutet till viss tillverkningssats, och vi har inte sett något liknande här, säger Charlotta Bergquist, klinisk utredare på Läkemedelsverket.

2,1 miljoner doser

I Sverige har cirka 2,1 miljoner doser av vaccinet getts till patienter. Totalt har cirka 1 500 biverkningsrapporter inkommit till Läkemedelsverket.

De allra flesta fallen gäller kända reaktioner som ömhet, rodnad och smärta vid injektionsstället.

I färre fall har illamående, kräkningar, magont, diarré, yrsel, utslag och sömnlöshet rapporterats.

Det vaccin vi använder i Sverige tillverkas i Belgien.

RTV SLO | MMC

Nova gripa: takoj po cepljenju je bolnici zastalo srce
Slovenj Gradec: Štirje resni primeri okužbe s H1N1

MMC, 26 november 2009 ob 16.50
https://www.rtvslo.si/zdravje/nova-gripa-takoj-po-cepljenju-je-bolnici-zastalo-srce/217787

Pri 77-letnici, sicer kronični bolnici, so se v sredo takoj po cepljenju proti novi gripi pojavile motnje srčnega ritma, ki so vodile v zastoj srca.

Cepilna ekipa, ki je na takšne dogodke pripravljena, je takoj ukrepala. Bolnico so sprejeli v bolnišnico, ker je dogodek časovno povezan s cepljenjem, pa se pričakuje morebitna vzročna povezanost z njim, so sporočili iz IVZ-ja. Kje se je to zgodilo in v kakšnem stanju je zdaj 77-letnica, nam na IVZ-ju niso želeli pojasniti.

V obvestilu za javnost pa so zapisali, da so do 25. novembra skupaj prejeli 76 prijav učinkov, ki so povezani s cepljenjem proti pandemski gripi. V večini primerov so bili pričakovani, blagi in kratkotrajni. Resni neželeni učinki so po njihovih zatrdilih izjemno redki, niso pa nepričakovani, zato imajo vse cepilne ambulante pripravljeno opremo za takojšnjo pomoč.

Slovenj Gradec: Štirje resni primeri okužbe s H1N1

Sicer pa je, ko gre za novo gripo, posebej živahno v splošni bolnišnici Slovenj Gradec, kjer je zaradi nove gripe hospitaliziranih sedem bolnikov, od tega se štirje zdravijo na intenzivni negi.

Bolniki na intenzivni negi so srednjih let, trije med njimi pa so v zelo kritičnem stanju in dihajo s pomočjo aparatov, je za MMC pojasnila dopisnica TV Slovenija **Duška Lah** in dodala, je stanje 44-letnega moškega, ki so ga v bolnišnično oskrbo sprejeli pretekli teden, še vedno zelo resno. V Splošni bolnišnici Slovenj Gradec so zaradi suma nove gripe obravnavali 30 zavarovancev, od tega je bilo 13 pozitivnih, šest pa izpuščenih v domačo oskrbo.

Lahova je še pojasnila, da je v koroški regiji na 100.000 prebivalcev 2.000 obolelih, virus nove gripe in hudih respiratornih obolenj pa se najbolj širi med mladimi. Na Koroškem so tako v zadnjih dveh tednih v osnovnih šolah in vrtcih našteli deset izbruhov tovrstnih obolenj.

Ljubljana: Stanje nosečnice resno, a stabilno

Iz ljubljanskega kliničnega centra so sporočili, da število obolelih s pandemsko gripo, ki prihajajo na zdravljenje, sicer narašča, a je hospitaliziranih še v mejah, kar pomeni, da vse dejavnosti potekajo v neomejenem obsegu. Še vedno je večina bolnikov hospitalizirana na Kliniki za infekcijske bolezni in vročinska stanja. Na intenzivni terapiji je še vedno nosečnica, katere stanje je še resno, a stabilno. Pacient, premeščen iz Maribora, pa še leži na oddelku za intenzivno interno medicino.

50-åring dog – av vaccinet

Aftonbladet, 26 November 2009
https://www.aftonbladet.se/nyheter/a/21vaWr/50-aring-dog-av-vaccinet

Första fallet i Sverige.

Personer med nytt hjärta uppmanas särskilt att vaccinera sig mot svininfluensan.
Den nytransplanterade mannen tog sprutan – och dog.
Aftonbladet kan i dag avslöja det första dödsfallet som orsakats av vaccinet.
Nu oroar sig myndigheterna för att människor inte ska våga vaccinera sig.
Mannen, som är i 50-årsåldern, avled nyligen efter att ha vaccinerat sig mot svininfluensan. Han hade dessförinnan genomgått en hjärttransplantation och vaccinet stötte bort det nya hjärtat.

Vaccinet ligger bakom

Fallet är unikt i Sverige. Åtta personer har tidigare dött inom loppet av timmar eller dagar efter vaccineringen, men det har vid samtliga tillfällen handlat om personer med svåra, kroniska sjukdomar.
För första gången har nu läkarna kunnat koppla vaccinet till ett dödsfall.
– Vaccinet är den direkta eller indirekta orsaken till mannens död, säger Ingemar Persson, läkare och utredare vid Läkemedelsverket.
Enligt uppgift fanns det speciella omständigheter kring mannen som inte var kända när han vaccinerades.
– Det går inte att säga att det var fel att vaccinera honom. Vi skriver ju till exempel fortfarande på vår hemsida att människor som genomgått hjärttransplantationer tillhör högriskgruppen och bör vaccinera sig. Men vi har fått ny kunskap som vi kan lära oss av.

Unikt fall

Enligt vad Aftonbladet erfar finns en betydande oro på Smittskyddsinstitutet för att det här unika fallet leder till att människor blir oroliga och inte vågar vaccinera sig.
Den döde mannens fall kommer att offentliggöras på en presskonferens i regeringshögkvarteret Rosenbad i dag. Där medverkar folkhälsominister Maria Larsson samt representanter för Läkemedelsverket, Socialstyrelsen, Smittskyddsinstitutet, Myndigheten för samhällsskydd och beredskap och Sveriges kommuner och landsting.

Ingen ny information

Det har hållits liknande pressträffar tidigare. När svininfluensan först bröt ut sades det att de skulle ske en gång i veckan, men det var nu en månad sedan förra gången.
Enligt Niclas Thorselius, pressekreterare hos Maria Larsson, är mötet i dag dock inte ett resultat av det nya fallet:
– Det är helt enkelt så att det inte funnits särskilt mycket att berätta de senaste veckorna.

THE FLU CASE

Man dies in Sweden from the "swine flu" shot - now 9 official deaths

The Flu Case, 26 November 2009, 08:02
https://web.archive.org/web/20100102041709/http://theflucase.com/index.php?option=com_content&view=article&id=2073%3Aman-dies-in-sweden-from-the-qswine-fluq-shot-now-9-official-deaths&catid=41%3Ahighlighted-news&Itemid=105&lang=en

Man dies in Sweden from the flu shot - now 9 official deaths

Aftonbladet reports that a man in his fifties died after having received the poisonous Pandemrix "swine flu" shot. He had been through a heart transplant operation and the shot made his body reject the new heart. Authorities in Sweden are now afraid fewer will want to take the vaccine.

"- It can not be said it was wrong to vaccinate this man. We do write on our home page that people who have been through heart transplants belong to the risk group and should get vaccinated. But we have new knowledge now which we can learn from." says Ingemar Persson, case investigator at the Swedish Medical Products Agency. "- The vaccine is the direct or indirect cause of this mans death." he continues.

Several involved agencies and departments will hold a press conference today to try to calm down worried citizens and again claim that the vaccine is "tested and safe".

The official death toll in Sweden is now nine but our sources claim there might be as many as 80 deaths. Then there are also many reports about abortions as a result of the shot, just like in other parts of the world. Officials are desperate to declare any deaths in proximity to the vaccinations as coincidental and therefor the official numbers can not be trusted. In fact, the whole official story regarding the "swine flu" in Sweden can no longer be trusted since it is clear that media together with the Swedish authorities have been and still are engaged in a massive propaganda campaign to vaccinate as many as possible without any clear declared reasons or logic.

The ties between scientists, politicians and the Pharma industry and WHO is also not clarified.

This is by far the biggest medical scandal in modern times in Sweden.

THE FLU CASE

Will we ever know how many people have died after taking Arepandrix in Canada?

The Flu Case, 26 November 2009, 15:23
https://web.archive.org/web/20100102011511/http://theflucase.com/index.php?option=com_content&view=article&id=2077%3Awill-we-ever-know-how-many-people-have-died-after-taking-arepandrix-in-canada-&catid=1%3Alatest-news&Itemid=64&lang=en

Swedish and German doctors have reported increased rates of severe allergic reactions and deaths in people who took GlaxoSmithKlines's Pandemrix since the end of October.

However, GSK did not see any need to withdraw the vaccine from the EU market, even though the Pandemrix jab has been linked with at least 20 deaths in Europe.

In Sweden alone, 1,500 side effects have been reported to the drug regulator, many severe.

How many people have suffered damage or death in Canada for GSK to take the drastic step of recalling 172,000 doses of Arepanrix (Pandemrix) vaccines over a "life-threatening" allergy?

AP on Fox News reports that the "pharmaceutical company GlaxoSmithKline says it has advised medical staff in Canada to not use one batch of swine flu vaccine for fear it may trigger life-threatening allergies.

GlaxoSmithKline spokeswoman Gwenan White said Tuesday the company issued the advice after reports that one batch of the swine flu vaccine might have caused more allergic reactions than normal.

She says the affected batch contains 172,000 doses of the vaccine. She declined to say how many doses had been administered before the advice to stop using them was given.

White says GlaxoSmithKline wrote to Canadian healthcare professionals advising them to stop using the batch on Nov. 18. She says a total of 7.5 million doses of the vaccine have been distributed in Canada."

The Canadian health authorites have a vested interest in downplaying the number of people who have suffered death or injury as a result of a vaccine they authorised under emergency procedures.

By attributing swine flu vaccine deaths to other causes (underlying illnesses), the number of deaths can be hidden from the general public.

There was a case in Finland where a woman in hospital was classified as dying from swine flu even though she died shortly after taking the swine flu jab.

Health Canada used an emergency procedure to authorise Arepanrix "based on limited clinical testing in humans under the provision of an Interim Order (IO) on October 13, 2009." The jab contains.
http://www.hc-sc.gc.ca/dhp-mps/prodpharma/legislation/interimorders-arretesurgence/prodinfo-vaccin-eng.php

Dave Mihalovic, a Naturopathic Doctor who specializes in vaccine research, write about the dangers of Arepandrix with squalene and mercury recently.
http://preventdisease.com/news/09/102609_Alert_Canadians_Arepanrix_vaccine_analysis.shtml

Arepanrix™ H1N1 (AS03-adjuvanted H1N1 pandemic influenza vaccine) is a two-component vaccine consisting of an H1N1 immunizing antigen (as a suspension), and an AS03 adjuvant (as an oil-in-water emulsion).

The H1N1 antigen is a sterile, colorless to slightly opalescent suspension that may sediment slightly in a 10mL vial. The antigen is prepared from virus grown in the allantoic cavity of embryonated hen's eggs. The virus is inactivated with ultraviolet light treatment followed by formaldehyde treatment, purified by centrifugation and disrupted with sodium deoxycholate.

The AS03 adjuvant system is a sterile, homogenized, whitish emulsion composed of DL-α-tocopherol, squalene and polysorbate 80 in a 3mL vial. http://pharmacritique.20minutes-blogs.fr/

Swedish and German doctors and patients have reported increeased incidents of allergic reactions and deaths to GSK's Pandemrix since the end of October. However, GSK did not see a need to withdraw the vaccine from the market. For GSK to take the step

Alert Canadians: Toxic ingredients in the Arepanrix H1N1 vaccine harm your health. – PreventDisease, 26 October 2009.
https://web.archive.org/web/20091029101856/http://preventdisease.com/news/09/102609_Alert_Canadians_Arepanrix_vaccine_analysis.shtml

Health Canada has authorized the sale of Arepanrix™ H1N1 vaccine based on no conclusive clinical testing. The authorization is based on the Health Canada review of available data on the quality, safety and immunogenicity of similar vaccines, which established the benefit/risk profile in favour of inoculating the Canadian population.

...

Read the Notice of Decision issued by Health Canada. The decision by the Health Minister was based on a belief (not qualified or informed) that immediate action is required to deal with the H1N1 risk. The assertion that the decision is based on limited clinical testing is being misapplied. There has been NO conclusive results from any clinical trials on the Arepanrix H1N1 vaccine.

Death of Health Care Workers in Switzerland?
Legal Obligation to be Silent Hampers Information

The Flu Case, 27 November 2009, 11:40
https://web.archive.org/web/20100102032338/http://theflucase.com/index.php?option=com_content&view=article&id=2087%3Adeath-of-health-care-workers-in-switzerland-legal-obligation-to-be-silent-hampers-information&catid=1%3Alatest-news&Itemid=64&lang=en

An emailer from Switzerland has said that one health care worker died and another ended up in a coma after taking the swine flu jab but the legal obligation of health personnel to remain silent restricts the flow of information.

He also said another doctor had the "entire flu" after the injection.

A doctor in Austria who signed the consent form and subsequently became ill from the injection was barred from seeking compensation.

"My girlfriend, half of whose family works in hospitals, said that after the vaccination of the personnel one woman died and the other is in a coma...And the doctor of the SI said that he more or less suffered the entire flu after the vaccination..."

"Meine Freundin, deren halbe Familie im Spital arbeitet, hat gesagt, dass nach der Impfung des Personals eine Frau gestorben ist und die andere im Koma liegt... Und der Arzt der SI sagt, dass er quasi die ganze Grippe durchmachte nach der Impfung..."

City resident gets Guillain-Barré after H1N1 shot

The Hamilton Spectator, 27 November 2009
https://web.archive.org/web/20091129131847/http://www.thespec.com/News/BreakingNews/article/680612

Public health says it's unlikely vaccine caused the autoimmune illness

A Hamilton adult got Guillain-Barré syndrome after getting the H1N1 flu shot.

But the public health department believes it's unlikely the vaccine caused the autoimmune disease that attacks the nervous system and results in sudden weakness or paralysis.

"We'll never know for sure," said Dr. Chris Mackie, one of Hamilton's associate medical officers of health. "The evidence is suggesting that it did not, but it is possible."

Health Canada lists GBS as a rare side effect of flu shots. The chances of getting it from a vaccination are one in a million.

Mackie points out that the risk of getting GBS from influenza itself is much higher at four to seven per 100,000.

"It's 40 to 70 times as likely," he said. "The main message is that all evidence gathered to date suggests that this vaccine is quite safe. It suggests there is not an increased risk of GBS with this vaccine. And it suggests that getting the vaccine is a lot safer than not getting the vaccine."

The Hamilton adult came down with GBS three weeks after getting the adjuvanted vaccine. However, the patient also had a mild viral illness about 10 days prior to the onset of symptoms, which could be responsible for the GBS.

The illness has many causes including influenza as well as other respiratory or gastrointestinal viral infections.

Most people have a full recovery.

This was not a severe case and the person is recovering at home.

"Our hearts go out to this patient and family," Mackie said. "This is a tragic event, but it does not signal a safety concern with this vaccine."

Antonia Sell

Impfung legt zwei Schweizer flach

Blick, 27 November 2009, 15:59
https://web.archive.org/web/20091130150828/http://www.blick.ch/news/schweiz/zwei-schweizer-im-spital-134420

Zürich – Zwei Personen liegen im Spital. Grund: Kurz nach der Impfung gegen die Schweinegrippe traten bei ihnen «schwerwiegende» allergische Reaktionen auf.

Die Impfung gegen die Schweinegrippe geht nicht so reibungslos über die Bühne, wie sich das Behörden und Bevölkerung gewünscht hätten. Gestern gab das Bundesamt für Gesundheit (BAG) bekannt, dass zwei Personen wegen «schwerwiegenden» allergischen Reaktionen ins Spital eingeliefert werden mussten.

«Die Reaktionen traten kurz nach der Impfung auf», sagt Joachim Gross, Pressesprecher von Swissmedic zu Blick.ch. Die beiden Personen hätten allerdings zu einer Risikogruppe gehört. «Ihr Zustand ist stabil.» Über das Alter und das Geschlecht der Betroffenen wollte Gross keine Auskunft geben. Auch welcher Impfstoff ihnen verabreicht wurde, wird nicht bekannt gegeben.

Unterschiede zwischen den Impfstoffen?

Insgesamt gibt es in der Schweiz drei Impfstoffe, die uns gegen die Schweinegrippe schützen sollen. Pandemrix wird von dem Pharmakonzern GlyxoSmithKline bereit gestellt und Novartis produziert Focetria und Celtura. Wie unterscheiden sich also diese drei Impfstoffe? «Der Hauptunterschied ist, dass sie auf verschiedene Arten produziert werden», erklärt Gross.

Pandemrix und Focetria werden auf embryonalen Hühnereiern gezüchtet, Celtura auf Hundezelllinien. Alle enthalten einen interaktiven Impfstoff, Adjuvantien (Substanzen, mit denen sich die Immunantwort verstärken lässt) und denselben Grippevirusstamm A/California/7/2009. Allerdings unterscheiden sie sich in der Zusammensetzung dieser Stoffe und in der Verabreichungsform und -häufigkeit. Auch wird Celtura zum Beispiel nicht für Kinder unter drei Jahren empfohlen.

Unterschiede zwischen den Impfstoffen lassen sich auch in den auf sie folgenden allergischen Reaktionen feststellen: Der Swissmedic wurden 75 allergische Reaktionen auf Pandemrix, 16 auf Focetria und 0 auf Celtura gemeldet. Wie kommt das? Die Unterschiede zwischen den Impfstoffen würden sich durch die Menge der verabreichten Dosen und die unterschiedliche Laufzeit erklären. «Celtura ist zum Beispiel noch nicht lange auf dem Markt», sagt Joachim Gross.

THE FLU CASE

Two Swiss in Hospital after Getting Swine Flu Vaccine

The Flu Case, 28 November 2009, 11:48
https://web.archive.org/web/20100102011615/http://theflucase.com/index.php?option=com_content&view=article&id=2109%3Atwo-swiss-in-hospital-after-getting-swine-flu-vaccine&catid=1%3Alatest-news&Itemid=64&lang=en

Two people in Switzerland had to go straight into hospital after getting a swine flu jab, reports Blick.

There is no information on their age or sex or state of health.

According to Swissmedic, the Swiss drug regulator, there have been 75 allergic reactions to Pandemrix 16 to Focentria and 0 to Celtura in Switzerland so far.

Ein Tag nach einer Schweinegrippe-Impfung ist ein 21 Jahre alter Mann am Morgen in seiner Wohnung in Karben verstorben. Ob die Impfung mit dem Tod des Mannes zusammenhängt oder ob die schwere Erkrankung die Todesursache gewesen ist, soll nun eine Obduktion klären.

Ein 21 Jahre alter Mann ist am Morgen in seiner Wohnung in Karben verstorben. Laut einer Mitteilung des Wetteraukreises war der junge Mann am Donnerstag von seinem Hausarzt gegen den Schweinegrippe geimpft worden. Er habe an einer schweren chronischen Vorerkrankung gelitten, sagte Kreissprecher Michael Elsaß. Ob die Impfung mit dem Tod des Mannes zusammenhänge oder ob die schwere Erkrankung die Todesursache gewesen sei, solle nun eine Obduktion klären.

Der Wetterauer Gesundheitsdezernent und Kreisbeigeordnete Ottmar Lich (FWG) teilte mit, er warne vor einer Panikmache. Der Kreis wolle "offen aufklären, um allen Mutmaßungen und Spekulationen zuvorzukommen". Die Schwere der Vorerkrankung des jungen Mannes ließen "keinen Hinweis darauf zu, dass die Impfung an sich lebensbedrohlich sein könnte". Allerdings, so Lich, sollte bei schweren chronischen Vorerkrankungen eine genaue Abwägung der Risiken im Gespräch mit dem Arzt erfolgen.

Young Man Dies in Germany After Getting the Swine Flu Jab

The Flu Case, 28 November 2009, 11:34
https://web.archive.org/web/20100102022619/http://theflucase.com/index.php?option=com_content&view=article&id=2106%3Ayoung-man-dies-in-germany-after-getting-the-swine-flu-jab&catid=1%3Alatest-news&Itemid=64&lang=en

A 21-year-old man in Karben, Germany, died one day after getting the swine flu jab at his GPs, reports the FAZ.

An autopsy is to be carried out to establish whether he died as a result of the jab. The 21-year-old had a history of illness and the chronically ill are a target group designated by WHO for the jab.

73-Jährige starb nach Grippe-Impfung

Westfälische Nachrichte, 27 November 2009, 18:16 Uhr
https://www.wn.de/archiv/73-jahrige-starb-nach-grippe-impfung-2266184?&npg

Billerbeck - Zwei Tage nachdem sie sich hat gegen die Schweinegrippe impfen lassen, ist eine 73 Jahre alte Frau aus Billerbeck gestern tot aufgefunden worden. Das hat das Kreisgesundheitsamt in Coesfeld am Abend bestätigt. Ob die Seniorin an den Folgen der Impfung gestorben ist, sei bisher aber unbekannt, teilte der münstersche Oberstaatsanwalt Schweer mit. Die Leiche wird heute obduziert. Ein Sprecher des Kreises sagte, es gebe zwar einen zeitlichen Zusammenhang zwischen Impfung und Tod; ein ursächliche Verbindung konnte er jedoch nicht erkennen. Die Frau habe eine "Grunderkrankung" gehabt, die auch Todesursache sein kann. Der Fall wurde dem Paul-Ehrlich-Institut gemeldet.

State Prosecutor Orders Autopsy on Woman's Death After Swine Flu Jab in Germany

The Flu Case, 28 November 2009, 11:38
https://web.archive.org/web/20100102040529/http://theflucase.com/index.php?option=com_content&view=article&id=2107%3Astate-prosecutor-orders-autopsy-on-womans-death-after-swine-flu-jab-in-germany&catid=1%3Alatest-news&Itemid=64&lang=en

A woman of 73 years old died in Billerbeck, Germany, after getting the swine flu vaccine on Thursday.

The local state prosecutor has ordered an autopsy to be performed.

Seniorin stirbt nach Impfung gegen Schweinegrippe

RTV SLO | MMC

24 urah dve novi žrtvi nove gripe:
V kritičnem stanju še štirje bolniki

MMC, 29. november 2009 ob 13.40
https://www.rtvslo.si/zdravje/v-24-urah-dve-novi-zrtvi-nove-gripe/218014

V slovenj graški bolnišnici je za posledicami nove gripe umrl 42-letni bolnik v Sloveniji, kmalu zatem pa še 29-letni bolnik v ljubljanskem kliničnem centru.

42-letni moški, okužen z virusom nove gripe, je v soboto zvečer umrl zaradi hude bakterijske pljučnice s sepso. V bolnišnico so ga zaradi slabega zdravstvenega stanja sprejeli 23. novembra iz Centra za usposabljanje, delo in varstvo Črna na Koroškem. Bolnik se je pred gripo tudi cepil, a prepozno.

Moškega s hudimi kroničnimi boleznimi so zdravili v enoti za intenzivno interno medicino, njegovo zdravstveno stanje pa je bilo že nekaj dni kritično. Bolnika so umetno predihavali s pomočjo ventilatorja, prav tako je prejemal specifično podporno in antibiotično terapijo.

V slovenjgraški bolnišnici se zaradi okužbe ali suma okužbe z virusom nove gripe zdravi deset bolnikov. Na oddelku za interno medicino jih zdravijo sedem - pri štirih je okužba z virusom nove gripe potrjena, pri treh bolnikih pa obstaja sum okužbe.

29-letnik z osnovno boleznijo

Glede moškega, ki je umrl v Ljubljani, v kliničnem centru še ne dajejo izjav. TV Slovenija je poročala, da naj bi šlo za 29-letnega moškega, ki je imel osnovno bolezen, za njegovo smrt pa je bila kriva nova gripa.

Alenka Kraigher z Inštituta za varovanje zdravja je za TV Slovenija povedala, da natančnega števila o obolelih z novo gripo nimajo, saj podatke zbirajo enkrat tedensko, povedala pa je, da je bilo prejšnji teden v bolnišnico zaradi gripe sprejetih 32 ljudi. Minister za zdravje **Borut Miklavčič** je povedal, da je šlo v vseh dosedanjih smrtnih primerih za kronične bolnike in da so v tem trenutku v kritičnem stanju štrije bolniki z novo gripo, trije v Ljubljani in eden v Slovenj Gradcu.

Stanje 44-letnega moškega boljše, a še vedno resno

Zdravstveno stanje 44-letnega bolnika, ki je bilo v preteklih dneh kritično, se je izboljšalo, vendar je še vedno resno. V celoti je odvisen od dihalne podpore z respiratorjem, je na dializi ter prejema specifično antibiotično terapijo ter vso podporno terapijo.

Zelo resno je zdravstveno stanje še pri enem bolniku, prav tako starem 44 let. Tudi ta bolnik diha s pomočjo ventilatorja, v bolnišnici pa bodo začeli dializo. Trije otroci - dva dojenčka in mladostnik - ki so zboleli za novo gripo in jih zdravijo na oddelku za pediatrijo, niso resneje ogroženi. Pri njih gre predvsem za dehidracijo zaradi povišane telesne temperature.

Strokovna skupina: Širjenje gripe se hitro nadaljuje

Na ministrstvu za zdravje se je sešla strokovna skupina za novo gripo skupaj s predsednikom vlade **Borutom Pahorjem** in z ministrom za zdravje **Borutom Miklavčičem**. Ponovno so ugotovili, da je cepljenje, ob izvajanju vseh preventivnih ukrepov, kjer je najpomembnejša dobra higiena, še vedno najboljša in daleč najbolj zanesljiva zaščita pred zbolevnostjo za novo gripo. Zaščita pa bo večja, če se bo cepilo čim več prebivalcev.

Glede sestanka strokovne skupine za novo gripo je Kraigherjeva povedala, da so naredili oceno stanja in ugotovili, da se širjenje gripe nadaljuje, saj je iz tedna v teden več obolelih. Kraigherjeva je še enkrat opozorila na ukrepe - umivanje rok, higiensko kašljanje in kihanje, kdor zboli, naj ostane doma, da ne okuži ostalih. "*Če se obolelim zdravstveno stanje poslabša, naj takoj poiščejo zdravniško pomoč*," je še povedala Kraigherjeva in dodala, da je najbolj varno še vedno cepljenje, in da je cepiva v Sloveniji dovolj.

Cepiva je dovolj, novi cepilni centri

Da bi zagotovili čim večjo dostopnost do cepljenja, se je strokovna skupina dogovorila za odprtje novih cepilnih centrov v večjih mestih, ki bodo delovali tudi ob koncih tedna. Slovenija je do zdaj prejela 100.000 odmerkov pandemskega cepiva proti novi gripi. Skupaj naj bi v letu 2009 Slovenija prejela 266.000 odmerkov cepiva, preostalo količino cepiva (534.000 odmerkov) pa do konca marca 2010. Glede na to, da je bilo do 22. novembra cepljenih dobrih 32.000 ljudi, je cepiva dovolj, so še zagotovili na IVZ-ju.

THE FLU CASE

Young Man dies in Slovenia after taking Swine Flu shot

The Flu Case, 30 November 2009, 11:42
https://web.archive.org/web/20100102021314/http://theflucase.com/index.php?option=com_content&view=article&id=2120%3Ayoung-man-dies-in-slovenia-after-taking-swine-flu-shot&catid=1%3Alatest-news&Itemid=64&lang=en

A 29 year old man in Slovenia who took the swine flu shot died two days later after he developed flu simptoms and severe bacterial pneumonia as a complication.

The man, who had a history of chronic illness, has been classified as dying from the swine flu: the official version is that the shot came too late.

In another case, a 77-year old woman's heart stopped five minutes after taking the swine flu jab last week but she was revived and is still in hospital.

So far only 32,000 people in Slovenia have taken GlaxoSmithKline's Pandermix swine flu jab.

The government has said there are 800,000 shots available for the population of 1.8 million.

The low rate of take-up of the jab comes amid growing scepticism in Slovenia about the links between big pharma and doctors.

Two months ago, it emerged that GSK had entered into secret and illegal contracts with the biggest hospital in Slovenia to fund doctors' "education."

The Minister for Health Borut Miklavcic who has a chronic heart disease and so should be in priority group for the swine flu shot, has said 'he doesn't want to be privileged as a minister' and so has not taken the shot.

S. Korean student dies of cerebral hemorrhage after receiving A/H1N1 vaccine

News XinhuaNet, 30 November 2009, 17:25
https://web.archive.org/web/20091203080117/http://news.xinhuanet.com/english/2009-11/30/content_12565798.htm

Seul, Nov. 30 (Xinhua). – A South Korean student had died of cerebral hemorrhage after receiving A/H1N1 vaccine, while health authorities said the death case is not associated with the vaccine, local media reported on Monday.

According to the Ministry for Health, Welfare and Family Affairs, a student, whose identity has not been revealed, died of cerebral hemorrhage on Saturday, four days after being inoculated with the A/H1N1 vaccine, Xinhua reported.

Investigation jointly carried out by experts, the health ministry, the Korea Food and Drug Administration and the National Institute of Scientific Investigation showed that there is not direct causality between the vaccine and the victim's cerebral hemorrhage, the ministry said.

Computer tomography showed serious bleeding in the brain that could indicate a prior dangerous medical condition, so the death may have been caused by an aneurysm, or an extreme swelling on the wall of an artery, in the brain, local media quoted experts who took part in the investigation as saying.

The health authorities also conducted an investigation to 516 students out of a total of 966 students who received the vaccine from the same production batch, and only 70 cases reported with minor side-effects, and the symptoms had vanished in a short period, the ministry said.

THE FLU CASE

German student files Criminal charges
after suffering damage from Pandemrix jab, accuses doctor of bodily harm

The Flu Case, 30 November 2009, 11:28
https://web.archive.org/web/20100102040431/http://theflucase.com/index.php?option=com_content&view=article&id=2119%3Agerman-student-files-criminal-charges-after-suffering-damage-from-pandemrix-jab-accuses-doctor-of-bodily-harm&catid=41%3Ahighlighted-news&Itemid=105&lang=en

A German student has filed a criminal complaint after suffering serious side effects from GlaxoSmithKline's Pandemrix shot.

The student also filed charges against the doctor who gave her the Pandemrix accusing him of committing bodily harm.

"This week I made a criminal complaint at the "Kripo" (Kriminalpolizei) in Heidenheim, Baden-Württemberg (Germany) and accused the WHO, the German Government and the doctor who gave me the Pandemrix of bodily harm.

The next I have to do is to do the same with the "Paul Ehrlich Institut" and the STIKO who recommended the vaccination and always informed the population that the jab is healthy," the student writes.

THE FLU CASE

Scottish Government reclassifying all Flu deaths as Swine Flu deaths

The Flu Case, 1 December 2009 11:47

https://web.archive.org/web/20100102015357/http://theflucase.com/index.php?option=com_content&view=article&id=2148%3Ascottish-government-reclassifying-all-flu-deaths-as-swine-flu-deaths&catid=41%3Ahighlighted-news&Itemid=105&lang=en

Information requested under the Freedom of Information (Scotland) Act 2002 reveals that there have been no deaths from seasonal influenza in Scotland since the start of the H1N1 Swine Flu pandemic according to the government's official.

At the same time, the Scottish Govenment has said that 48 people have died from the swine flu, according to a report in The Scotsman:

Lyndsay Moss. "**Swine flu claims 48th victim in Scotland**. **-** 1 December 2009

The death toll linked to swine flu in Scotland has risen to 48, the Scottish Government said yesterday.

Health secretary Nicola Sturgeon confirmed that an adult from the NHS Ayrshire and Arran Health Board area had died after contracting the H1N1 virus. The patient had underlying health conditions."

The absence of any deaths attributed to the seasonal flu in Scotland and the simultaneous jump in deaths attributed to the swine flu will spark fears that the Scottsh government is deliberately manipulating data to exaggerate the dangers of the swine flu by reclassifying all seasonal flu deaths as swine flu deaths in order to be able to better justify a mass swine flu vaccination campaign.

Many of the suspected swine flu cases have tested negative in the UK with only about 15,000 cases confirmed in labs according to another Freedom of Information request.

It, therefore, seems highly unlikely that every single person who has died in Scotland from the flu so far this year has died from the swine flu while not a single one has died from the seasonal flu.

This is the FOI request:
Chief Medical Officer and Public Health Directorate
Public Health Division
T: 0131-244 5542 F: 0131-244 2157
E: [email address]
Mr McGillivray

By email to: [FOI #22372 email]

Our ref: FoI/09/01511
17 November 2009

Dear Mr McGillivray

Thank you for your email of 2 November which requested information under the Freedom of Information (Scotland) Act 2002 on the number of deaths from seasonal influenza in Scotland since the start of the H1N1 Swine Flu pandemic. I have been asked to provide a response to the question you have raised.

Thus far this flu season (2009-10), there have been no deaths from seasonal influenza communicated to colleagues in NHS Health Protection Scotland. However, I detail below some of the difficulties that exist around identifying deaths as a result of influenza.

The General Register Office for Scotland (GRO(S)) receives all data held on each death registered in Scotland and this is collated into the GRO(S) Annual Report. From time to time, GRO(S) also compiles reports comparing trends over time. If influenza is recorded at any point on a death certificate this information is counted in these official statistics.

GRO(S) have recently produced a report compiling information on influenza deaths across the period 1990 to the end of the 2008/2009 seasonal flu season, and this is available at:
https://web.archive.org/web/20100102015357/http://www.gro-scotland.gov.uk/statistics/publications-and-data/increased-winter-mortality/increased-winter-mortality-in-scotland-2008-09.html

In this report, GRO(S) comment on the difficulty of capturing data on influenza related deaths. In overview, it is likely that to date there has been under-reporting of influenza, which is due to the fact that recording of deaths is often ascribed to a complication of influenza rather than to influenza itself. In many cases, the episode of influenza has passed, and the physician reporting the death may not record this infection on the death certificate. Furthermore a number of experts suggest that stress on the body caused by influenza may precipitate heart attacks, strokes and other conditions in those who are already in poor physical health. It will be these rapidly fatal conditions that appear on the death certificates rather than influenza itself. This may also explain partly the excess winter deaths due to stroke and heart attacks, although other factors such as the cold temperatures may also be attributable. To overcome this difficulty, the GRO(S) report describes excess deaths compared to that expected for each season.

In September this year, the Chief Medical Officer Dr Harry Burns issued a letter to NHS Boards setting out instructions and providing national guidance to those responsible for certifying death certificates. Dr Burns requested that death certificates should record the whole sequence of conditions and events leading up to death, which in future will provide better understanding when establishing the number of deaths where seasonal influenza has been a contributory factor.

If you are unhappy with this response to your request, you may ask us to carry out an internal review, by writing to Dr Kevin Woods, Director General - Health, Floor 1E.07 - St Andrews House, Regent Road, Edinburgh, EH1 3DG. Your request should explain why you wish a review to be carried out, and should be made within 40 working days of receipt of this letter, and we will reply within 20 working days of receipt. If you are not satisfied with the result of the review, you then have the right to make a formal complaint to the Scottish Information Commissioner.

Yours sincerely

Rona Watters
Health Protection Team

Le Monde

La grippe H1N1 a fait 92 morts en France

Le Monde avec AFP et Reuters, 3 Décembre 2009, à 13h33,
https://www.lemonde.fr/epidemie-grippe-a/article/2009/12/03/la-grippe-h1n1-a-fait-92-morts-en-france_1275490_1225408.html

Quatre vingt-douze décès liés au virus grippal H1N1 ont été enregistrés en France métropolitaine depuis le début de l'épidémie, dont quatorze chez des personnes sans facteur de risque connu, selon le dernier point de situation arrêté au 1er décembre. Sur le total, vingt-quatre décès ont été signalés au cours de la semaine passée, précise l'Institut de veille sanitaire (InVS).

Neuf cent quatre-vingt-treize mille ont consulté la semaine dernière pour des symptômes grippaux, soit une augmentation de 40 % par rapport à la période précédente, a précisé la ministre de la santé lors d'une conférence de presse. Roselyne Bachelot a toutefois souligné que certains signes laissaient espérer un ralentissement de la progression du virus. Depuis le début du mois d'août, *"trois millions de personnes ont été infectées par le virus grippal pandémique en France"*, a-t-elle déclaré, soit *"plus que pour toute la saison de grippe saisonnière 2008-2009"*. Depuis le début de l'épidémie, 481 cas graves ont été hospitalisés, dont 18 % d'enfants de moins de quinze ans.

Vaccins: 567 Événements Indésirables

La vaccination contre la grippe A monte en puissance avec environ 1,3 million de personnes vaccinées en dix-huit jours en France métropolitaine. Dans un entretien au *Monde*, la ministre de la santé affirme que 30 millions de personnes pourront être vaccinées d'ici à la fin de février. Afin de faire face à l'afflux des demandes, tous les centres de vaccination seront désormais ouverts de 8 heures à 22 heures du lundi au samedi, a par ailleurs précisé le premier ministre. Dans les grandes agglomérations, sur décision des préfets, les centres seront ouverts sept jours sur sept à partir de dimanche prochain.

Sur les 1,3 million de personnes vaccinées, 567 événements indésirables ont été enregistrés, a indiqué, jeudi, l'Agence française de sécurité sanitaire des produits de santé (Afssaps). Le vaccin Pandemrix, avec adjuvant, de GlaxoSmithKkline, le plus utilisé jusqu'à maintenant, a été à l'origine de 562 signalements d'effets indésirables, soit 0,5 pour 1 000 doses administrées.

97 % des cas rapportés étaient d'intensité bénigne à modérée : douleurs à l'endroit de l'injection, réactions inflammatoires, douleurs générales, fièvre, fatigue, syndrome grippal... Vingt-quatre nouvelles observations *"médicalement significatives"* ont été rapportées, entraînant une gêne fonctionnelle ou une incapacité temporaire. Sept nouvelles observations graves ont été signalées, dont deux réactions allergiques (oedème de Quincke, choc anaphylactique) d'évolution favorable, deux cas de paresthésie (fourmillements dans les membres) et un cas de douleurs thoraciques. Deux cas d'embolie pulmonaire et pneumopathie sont en cours d'évaluation.

THE FLU CASE

German drug Regulator denies 15 deaths linked to Swine Flu shots

The Flu Case, 3 December 2009, 13:57
https://web.archive.org/web/20100102043453/http://theflucase.com/index.php?option=com_content&view=article&id=2175%3Agerman-drug-regulator-denies-15-deaths-linked-to-swine-flu-shots&catid=1%3Alatest-news&Itemid=64&lang=en

The German drug regulator, the Paul Ehrlich Institute (PEI), has said it has found no evidence that any of the15 people reported by doctors as dying after getting the swine jab actually died as a result of the shot.

12 of the 16 of the members of a key vaccination committee of the PEI have links with the pharmaceutical industry, and this regulator was also responsible for allowing the toxic and untested swine flu jab onto the market in the first place.

It is, therefore, legitimate to raise the question of whether there is a conflict of interest in the case of the PEI and whether the investigation into the possible deaths of people taking the swine flu should be conducted by genuinely independent authorities.

Beat Kraushaar und Georg Nopper

Impfung gefährlicher als Virus?

Blick, 3 Dezembre 2009, 19:50

https://web.archive.org/web/20091207004831/http://www.blick.ch/news/schweiz/schweinegrippe

Bern – Die neuesten Zahlen sind nicht gerade beruhigend. Bereits kam es nach der Schweinegrippe-Impfung zu 72 schwerwiegenden Fällen.

Vor rund drei Wochen hat das grossangelegte Impfen gegen die Schweinegrippe begonnen. Wie die heute Nachmittag veröffentlichten neusten Zahlen des Heilmittelinstituts Swissmedic aufzeigen, ist das Pieksen doch nicht so harmlos wie von den Gesundheitsbehörden und Ärzten dargestellt.

Bereits meldeten die Mediziner 197 Vorfälle bei der Schweinegrippe-Impfung. Die Zahlen der unerwünschten Nebenwirkungen im Detail:

44 Meldungen mit schwerwiegenden und erwarteten Reaktionen
28 Meldungen mit schwerwiegenden und unerwarteten Reaktionen
5 Meldungen bei Schwangeren
42 Meldungen mit laufenden Rückfragen (Nebenwirkungen noch nicht definiert)

Die als nicht schwerwiegend eingestuften Reaktionen sind hier nicht separat aufgelistet. Sie sind aber in den insgesamt gemeldeten Fällen enthalten. Die schwerwiegenden erwarteten Fälle betreffen vor allem starke Allergie-Reaktionen. Beim Impfstoff Pandemrix und Focteria besteht Gefahr bei Patienten mit einer Eiweiss-Allergie, bei Celtura haben Patienten mit Tierhaar-Allergie unerwünschte Reaktionen zu befürchten.

Zwei Schwangere haben nach der Impfung ihr Kind verloren. In einem Fall ist ein Zusammenhang des Kindstodes mit der Impfung eher unwahrscheinlich. Im zweiten Fall klärt Swissmedic die Ursache noch ab.

Aufhorchen lässt die Zunahme der unerwarteten schwerwiegenden Reaktionen auf den Pieks. Ihre Zahl hat sich seit der letzten Erhebung vom 21. November mehr als verdoppelt.

Die von Swissmedic veröffentlichten Zahlen sind nur die Spitze des Eisberges. Denn gemeldet werden nur Vorfälle, die gewisse Kriterien erfüllen.

Wie hoch die Gesamtzahl der Fälle mit unerwünschten Nebenwirkungen wirklich ist, können weder Swissmedic noch das Bundesamt für Gesundheit (BAG) sagen.

Vaccine more dangerous than Virus? Asks Blick

The Flu Case, 4 December 2009 16:40

https://web.archive.org/web/20100102020624/http://theflucase.com/index.php?option=com_content&view=article&id=2186%3Avaccine-more-dangerous-than-virus-asks-blick&catid=1%3Alatest-news&Itemid=64&lang=en

72 cases of severe side effects from the swine flu jab have been reported in Switzerland, including two pregnant women who lost their babies after the jab, reports Blick, the most popular newspaper in the country.

Blick says the number of severe reactions reported by the Swiss drug regulator, Swissmedic, are just the "tip of the ice berg".

Swissmedic only includes cases that fulfil "certain criteria," says Blick.

At least five people are reported to have died in Switzerland after receiving the jab about three weeks into the mass vaccination campaign.

Severe H1N1 reactions in 48 Canadians

Toronto Star, 4 December 2009
https://www.thestar.com/life/health-wellness/severe-h1n1-reactions-in-48-canadians/article_2eaf2693-dda8-5c74-8c02-f374c7857647.html

Ottawa – The Public Health Agency of Canada says 48 people nationwide have experienced severe allergic reactions to the swine flu vaccine since the immunization campaign began two months ago.

The agency updated its vaccine surveillance report Friday to show 2,574 adverse reactions to the H1N1 influenza vaccine had been reported by provinces and territories as of Nov. 20.

About 12.3 million doses of the vaccine had been shipped across the country by that point.

The report says 135 of those side effects were considered serious.

Forty-eight of those serious cases involved anaphylaxis, a severe reaction that some people can experience when they are allergic to bee stings or peanuts and can be treated with an immediate shot of adrenaline.

One person has died following an anaphylactic reaction, which Quebec health authorities have said was an octogenarian in that province.

The rate of anaphylaxis so far has been about 0.39 reactions out of 100,000 doses distributed.

Vaccine manufacturer GlaxoSmithKline Inc. is producing the Canadian order of 50.4 million doses at its plant in Ste-Foy, Que.

Victoria Nicks

New side effect from GlaxoSmithKline's H1N1 vaccine:
Second swine flu shot gives kids fever and more

The Flu Case, 4 December 2009, 7:22 AM
https://web.archive.org/web/20100102043936/http://theflucase.com/index.php?option=com_content&view=article&id=2179%3Agsk-shot-gives-kids-fever-and-more-reports-victoria-nicks&catid=1%3Alatest-news&Itemid=64&lang=en

Getting a second swine flu shot is causing side effects in children

According to the European Medicines Agency, GlaxoSmithKline has reported that side effects are more common in children after the second dose of the Pandemrix H1N1 injection. The necessity for the second swine flu shot for kids is a matter of contention between GlaxoSmithKline and the European health authorities.

Second H1N1 vaccine injection side effects in children

The H1N1 injection commonly causes mild side effects, such as redness and soreness at the injection site, and a runny nose. Children who receive the second Pandemrix swine flu shot, however, are more likely to get fever, experience muscle pain, and be irritable, or drowsy.

Dosage of the GlaxoSmithKline swine flu shot

GlaxoSmithKline has stated that a single dose of the swine flu shot is sufficient to provide immunity to the swine flu (H1N1) virus. European drug regulators, however, recommend the second dose for children, even babies as young as 6 months.

THE FLU CASE

Novartis Managers being investigated after man dies in Italy from celtura jab

The Flu Case, 5 December 2009, 15:38
https://web.archive.org/web/20100102033449/http://theflucase.com/index.php?option=com_content&view=article&id=2193%3Anovartis-managers-being-investigated-after-man-dies-in-italy-from-celtura-jab&catid=1%3Alatest-news&Itemid=64&lang=en

State prosecutors in Salerno, southern Italy, have launched a criminal probe into two Novartis managers and 14 doctors in connection with the death from heart failure of a man directly after he was vaccinated with Novartis's Celtura material, reports Polskaweb.

Slovenian prosecutors are also looking into the death of a 20-year-old man after he got GlaxoSmith-Kine's Pandemrix jab.

The probes are being conducted independently of the European and other national drug regulator, which, have consistentaly denied any link between severe reactions reported to them by doctors and patients and the jab.

The European drug regulator, the EMEA, is two thirds funded by pharma companies, raising concerns of a conflict of interest.

Antti Heikkilä

H1N1 Rokotuksen Komplikaatioita

Antti Heikkila, 7 December 2009
https://web.archive.org/web/20091215005622/http://www.anttiheikkila.com/index.php?id=2&art=152

Oheisena tähän mennessä kertyneitä palautteita. Olen keskustellut muutaman TK lääkärituttavan kanssa ja heidän mielestä koko rokotusrumba on mielipuolista. Terveet lapset sairastuvat. Näillä sairastumisilla on yhteinen piirre. Flunssan tapainen sairaus puhkeaa muutaman päivän korkeintaan viikon kuluttua rokotuksesta ja oireet voivat olla hyvinkin rajuja.
Näistä rokotuskomplikaatioista voi myös lukea blogieni vastauksista. Toivon, että lähettäisitte kokemuksistanne tietoja osoitteeseen drantti@gmail.com.

see:
https://web.archive.org/web/20091215005622/http://www.anttiheikkila.com/index.php?id=2&art=152

Finnish doctor compiles list of Swine Flu Damage as authorities do nothing

https://web.archive.org/web/20100102023738/http://theflucase.com/index.php?option=com_content&view=article&id=2214%3Afinnish-doctor-compiles-list-of-swine-flu-damage-as-authorities-do-nothing&catid=1%3Alatest-news&Itemid=64&lang=en

A Finnish medical doctor Antti Heikkilä has started collecting reports of side effects suffered by people who took the swine flu jab as authorities – many of whose leading members have proven financial links to big pharma – play down the damage.

Heikkila reports 29 separate, confirmed cases concerning about 100 people suffering a range of symptoms from a little pain or ache, to flu like symptoms, fluid in lungs, hallucinations after Tamiflu treatment as well as death and miscarriages.

One nurse (midwife) reported a night when there were no other cases than miscarriages. Also one child was given the jab even though parents did not give permission.

Heikkila started collecting reports after 23rd of November when about 1 million people in Finland were vaccinated.

There needs to be a criminal investigation into the national and international authorities such as the EMEA, which is two thirds funded by pharmaceutical companies, and whether they are systematically suppressing evidence of the damage and death caused by these vaccines for profit.

THE FLU CASE

Damage caused by Swine Flu jab suppressed in USA

The Flu Case, 8 December 2009 13:37

https://web.archive.org/web/20100102043240/http://theflucase.com/index.php?option=com_content&view=article&id=2206%3Adamage-caused-by-swine-flu-jab-suppressed-in-usa&catid=1%3Alatest-news&Itemid=64&lang=en

"I would like to share this...but due to American HIPAA Laws I have to be very vague... I know of a middle-aged man who has become ill after receiving the Swine Flu Vaccine. He developed Guillain-Barre syndrome and is now intubated in an Intensive Care Unit in Tennessee. I continue to see patients of all ages come in to the Emergency Room with nausea, vomiting, headaches, Bell's Palsy, and chest pain after receiving the Swine Flu Vaccine... It usually takes 2-4 days after the poisonous vaccine for side effects to begin," emails a medical professional from the USA.

Swine Flu Vaccine Side Effects: Increasing number of Guillain-Barre syndrome cases

Examiner, 10 December 2009
https://web.archive.org/web/20100102031612/http://theflucase.com/index.php?option=com_content&view=article&id=2226%3Aswine-flu-vaccine-side-effects-increasing-number-of-guillain-barre-syndrome-cases&catid=1%3Alatest-news&Itemid=64&lang=en

Guillan-Barre syndrome is a dangerous, potential swine flu vaccine side effect.

While statistics have not been released proving that swine flu vaccine side effects are more dangerous than typical flu vaccine side effects, the number of reported cases of Guillain-Barre syndrome and fatalities due to the swine flu vaccine appear to be rising.

Swine Flu Vaccine Side Effects: Danger of Guillain-Barr syndrome

In the United States, Jordan McFarland, a 14-year old from Virginia has been diagnosed with Guillain-Barre syndrome only hours after having the H1N1 swine flu vaccine administered.

Elsewhere in the world, a woman in France that is employed as a health worker was diagnosed with Guillain-Barre syndrome only six days after receiving the H1N1 vaccine.

While American officials are reluctant to announce anything, Japanese, Chinese, and Swedish officials have caught the world's attention after reporting devestating swine flu vaccine side effects, including an increasing number of deaths occuring after receiving the H1N1 vaccine.

Additional H1N1 Swine Flu Vaccine Side Effects

Other reported side effects of the H1N1 vaccine include:
Redness and swelling at the injection site
Mild fever
Muscle aches
Fatigue

Additionally, China conducts a daily survey and in its recent report, 54% of its residents said they would not receive the H1N1 swine flu vaccine because of the potential side effects.

64 pessoas morreram no Japão depois de terem sido vacinados contra gripe dos porcos

Raiva Escondida, 10 Dezembro 2009
https://raivaescondida.wordpress.com/tag/swine-flu/

Um total de 64 pessoas morreram no Japão até ao mês de dezembro, entre 80 pessoas após terem recebido o "tiro" da vacina dos suínos, de acordo com um relatório no jornal Mainichi. Um menino morreu imediatamente depois de receber a vacina. Um outro homem foi encontrado inoperante na sua casa quatro dias depois de ter recebido a vacina dos suínos. Queixou-se do estômago e vomitou e morreu mais tarde em repouso junto dos seus familiares. O médico indicou que sua morte não estêve ligada com a vacina H1N1 e que o efeito é lateral, era somente um mal de estômago.

Tem havido muitos relatórios das mortes relacionadas a Tamiflu no Japão, incluindo jovens que caemmortos nos seus apartamentos após terem tomado Tamiflu, apresentando acções violentas, irracionais e alucinações.

THE FLU CASE

64 people die in Japan after getting Swine Flu jab

The Flu Case, 10 December 2009 11:21
https://web.archive.org/web/20100102005953/http://theflucase.com/index.php?option=com_content&view=article&id=2222%3A64-people-die-in-japan-after-getting-swine-flu-jab&catid=1%3Alatest-news&Itemid=64&lang=en

A total of 64 people have died in Japan as of December 8th after receiving the swine flu shot, according to a report in the newspaper Mainichi.

One teenage boy died immediately after taking the shot.

Another man was found dead in his home four days after he received a swine flu jab.

He complained of stomach ache and vomited and died later at home on his own.

His doctor stated his death was not linked with H1N1 flu shot and that the side effect of the shot was only a stomach ache.

In addition, there have been many reports of deaths related to Tamiflu in Japan, including young people falling to their deaths from their apartment after taking Tamiflu, violent and irrational actions and hallucinations.

But while the Japanese corporate media appears to downplay the side effects of the swine flu jab and of Tamiflu, it exaggerates the threat of the mild swine flu.

According to Sankei news on November 27th, more than 100,000 people have been infected with swine flu in Japan. The total number of deaths caused by the swine flu is over 100 people, it is maintained.

The Japanese government completed the first phase of its mass vaccination programme in the middle of November, after giving 450,000 people the jab.

Children and pregnant women were given the priority groups vaccinated using a swine flu vaccine made in Japan.

WHO Denies Link Between Swine Flu Vaccine and Illnesses, Deaths

The Flu Case, 12 December 2009
https://web.archive.org/web/20100102024239/http://theflucase.com/index.php?option=com_content&view=article&id=2242%3Awho-denies-link-between-swine-flu-vaccine-and-illnesses-deaths&catid=1%3Alatest-news&Itemid=64&lang=en

Ref: St. Nebehay. **Deaths not linked to H1N1 vaccine**: WHO**.** Reuters, 19 November 2009
http://www.reuters.com/article/idUSTRE5AI2BL20091119?feedType=RSS&feedName=he
The World Health Organization said on Thursday the H1N1 vaccine had been cleared of blame for 41 deaths which health authorities worldwide had investigated after suspicions they might have been caused by the inoculation. ... See original article above

Joseph Mercola
WHO Denies Link Between Swine Flu Vaccine and Illnesses, Deaths

This would be great news were it not for the fact that reports of adverse reactions to this vaccine continue to pour in from around the world. Consider for example:

In Canada, GlaxoSmithKline recalled an entire batch of its H1N1 vaccine, Arepanrix, after an unusual number of anaphylactic and other allergic reactions were reported.

In the U.S., authorities are investigating dozens of reports of side effects across the country. For example, one victim is a New York City six-year old who was vaccinated without her parents' knowledge, and ended up in the hospital afterward; several others are high school students in Mississippi who went to the hospital with allergy-like symptoms immediately following their injections; and a Virginia 14 year old was diagnosed with Guillian-Barre Syndrome shortly after his shot.

And these are just a sampling of what legitimate, mainstream news agencies have been reporting, while the WHO insists that safety is not a problem with this vaccine.

When you also take into consideration the blogs that are proliferating with complaints of side effects – such as miscarriages – (be aware: health officials don't count blogs as legitimate) the WHO's denials really don't make sense.

I, for one, am truly curious about what kinds of "investigations" have been done, and how they've been able to completely rule out the vaccine as a potential cause of all those side effects and deaths.

I find it very interesting that if someone exhibits flu like symptoms and then dies, they officially died from the swine flu, even though the CDC no longer requires lab testing to verify infection.

And when someone dies shortly after receiving the flu shot, they died from some underlying cause that would have crippled or killed them anyway, no matter how young or healthy they were prior to the shot!

This kind of unscientific, illogical nonsense is downright infuriating.

It's frustrating that health officials who call the shots, literally and figuratively, won't address the professional and ethical thing to do here, which is to thoroughly investigate every single adverse report, especially the "unofficial" miscarriages.

Go to any of these websites and you will see that the reason the blogs are popping up is because no one seems to be collecting miscarriage data, mainly because doctors appear to be discounting the unfortunate events as having nothing to do with the vaccine. But why should these blogs be necessary? Isn't it time for the WHO to demand that all miscarriages after an H1N1 vaccine be reported?

What's frightening is that, instead of looking more closely at the adverse reactions, the WHO is criticizing the U.S. for refusing to use dangerous adjuvants such as squalene in its H1N1 vaccines!

Adjuvants can double or triple the number of vaccines that can be created with a small amount of antigen. And since the WHO was hoping that rich countries would donate leftover vaccines, the fact that the U.S. isn't using adjuvants – and therefore won't have as many leftover vaccines – has the WHO upset.

It also has upset vaccine makers, who could have tripled their profits on an adjuvanted vaccine. Congress is still out on this issue. However, the whining and moaning did produce a reaction from the National Institute of Allergy and Infectious Diseases, which decided to award researchers and companies $60 million to develop new adjuvants for use in the U.S.

Will they be any safer than the ones already created? I highly doubt it. Instead, we'll probably see even more vaccines with highly questionable novel adjuvants that will not have been thoroughly tested prior to marketing.

As it is, having leftover vaccines to donate to the WHO might not be a problem in the U.S. As reported on Fox News as well as in numerous mainstream media, interest in this shot is waning so much that some state and county health departments in the U.S. are offering the vaccine to just about anybody who will take it.

Two counties in northeast Indiana, for example, have so much H1N1 vaccine left over that they are lifting all restrictions on who gets it. The demand just isn't there, even at doctors' offices, Indiana health officials told the Fort Wayne Journal Gazette.

Similar reports are coming from the rest of the nation too. In Utah, the Salt Lake Tribune reported December 1st that the Davis County Health Department had 9,000 doses of shots or nasal spray available, but only 1,500 residents had picked up reservation tickets for them.

The same is true from south Florida to Oklahoma to Montana, where demand for the vaccine is so low that Ravalli County, Montana, health officials decided to take the shots on the road in a rolling vaccine clinic in an effort to get rid of their leftovers.

Ravalli County had planned to administer 2,000 shots a day at two recent Saturday clinics, according to the Ravelli Republic.They even had lined up an army of volunteers to help with the crowds expected at the clinics. But after all the preparation and blitzing, the only thing they had to show for it was a cloud of dust, with just 700 doses being administered over both all-day clinics.

There still are some areas where health officials have managed to keep up the demand for the vaccine, mostly by selling the idea that another wave of H1N1 might be on its way. But the point is, this pandemic has proven to be a disappointing blip on the radar, with far fewer people being stricken by this flu than was predicted.

The latest news from Quest Diagnostics Health Trends, which tracks laboratory testing services for emerging diseases, confirms that H1N1 peaked in October 2009.

So why not admit this flu for the non-event that it is? The H1N1 "pandemic" has proven to be nothing but a practice drill to see how fast nations and health officials respond when WHO calls a war.

The only problem with that is, what happens if, like in the story of "The Little Boy Who Cried 'Wolf'" nobody pays attention when a real pandemic develops? In the meantime, let's start taking all adverse reaction reports on this vaccine seriously, instead of denying that they are related.

AFTONBLADET

29-åring förlamad efter vaccinering

Aftonbladet, 12 December 2009
http://www.aftonbladet.se/nyheter/svininfluensan/article6281571.ab

En 29-årig man vårdas i respirator efter att ha fått vaccin mot svininfluensa, rapporterar Västgöta-Bladet.

– Det är fruktansvärt, säger mamman till tidningen.

Nu misstänker läkarna att mannen drabbats av en neurologisk sjukdom som sammanföll med vaccineringen.

Mannen fick vaccin mot svininfluensa på tisdagen förra veckan.

– På onsdagen hade han ont i armen, på torsdagen fick han ont i ryggen. På fredagen fick han stickningar i fingrar och ben, säger 29-åringens mamma till Västgöta-Bladet.

När symptomen förvärrades ytterligare på lördagen ringde mannen till sjukvårdupplysningen, men enligt mamman fick han rådet att vila och ta värktabletter. Då ringde 29-åringen till sin mamma.

– Det var hemskt, jag hörde knappt att det var han, han lät sluddrig och sa att han hade krupit fram till telefonen, berättar mamman för Västgöta-Bladet.

Respirator

Mamman åkte direkt hem till sonen och insåg genast att han behövde vård.

– När han skulle sitta i soffan ramlade huvudet åt olika håll och kroppen också, säger hon till Västgöta-Bladet.

Hon ringde återigen till sjukvårdsupplysningen som ordnade med ambulans till Skaraborgs sjukhus. Där bedömde läkarna att 29-åringen behövde vårdas vid Sahlgrenska sjukhuset i Göteborg.

Mannen är nu förlamad och vårdas i respirator, men är vid fullt medvetande.

– Han formar läpparna. Han säger ”Jävla spruta” och så frågar han efter sin flickvän, säger mamman till tidningen.

Allvarligt

Sjukhuset har gett mannen en femdagarsbehandling. Helene Sandgren, pressinformatör vid Sahlgrenska, säger till Aftonbladet att man utreder vad som orsakat mannens tillstånd.

– Man kan inte säga säkert att det är vaccinet som är orsaken. Tillståndet är allvarligt men har förbättrats i dag.

Enligt 29-åringens mamma har mannen återfått lite rörelseförmåga i armar och ben.

Kan bli helt återställd

Enligt Västgöta-Bladet pekar symptomen på att 29-åringen har Guillain-Barrésyndromet, som är en neurologisk sjukdom.

Tidningen skriver att cirka 150 personer i Sverige insjuknar varje år. Guillain-Barrésyndromet är en stigande motorisk förlamning av muskulaturen. Om förlamningen påverkar andningen behöver den drabbade hjälp av en respirator. Vanligtvis går förlamningen tillbaka efter behandling, uppger Västgöta-Bladet.

– När man vaccinerar fyra miljoner människor på åtta veckor kommer det tidsmässigt att sammanfalla med att andra allvarliga sjukdomar bryter ut, som hade kunnat bryta ut i alla fall, säger Anders Hagman, chefläkare på Skaraborgs sjukhus, till tidningen.

– De säger att de allra flesta blir helt återställda, men man vet inte, säger 29-åringens mamma till Västgöta-Bladet.

THE FLU CASE

29-year old Man Paralyzed after getting the "Swine Flu" Shot

The Flu Case, 12 December 2009, 18:45

https://web.archive.org/web/20091220035426/http://www.theflucase.com/index.php?option=com_content&view=article&id=2248%3A29-year-old-man-paralyzed-after-getting-the-qswine-fluq-shot&catid=1%3Alatest-news&Itemid=64&lang=en

A 29-year old Swedish man received the poisonous Pandemrix "swine flu" shot last Tuesday and started to get the by now considered normal severe pain in the arm. Two days later he got back pains and on Friday he had prickly feelings in fingers and legs. On Saturday he called the Hospital for advice and they said he should take pain killers. He then called his mom.

"- It was horrible, I hardly heard it was him, he could not speak properly and said he had crawled on all fours to the telephone." his mom says. She went directly to his home. "- When he tried to sit in his sofa, his head would tip over in different directions and so did his whole body". She called for an ambulance and at the local hospital they decided he needed specialist care at the Sahlgrenska Hospital in Gothenburg.

The man is now paralyzed and is connected to a respirator. He is fully consious. "- He shapes his lips." his mother says, "- He says ' Fucking Shot ' and he aslo asks for his girlfriend".

The doctors in the hospital are "investigating" what has happened to him.

And again: "- One can not say for sure it was the vaccine that caused this. His condition is serious but has been stabilizing today" says Helene Sandgren, the hospital press informer.

His mother says he has started to regain some of his mobility in his legs and that doctors claim "most people will get better or completely well again" but one never knows.

Hundreds fall ill after having swine flu jab

Herald.ie, 14 December 2009.
https://web.archive.org/web/20100114125712/http://www.herald.ie/national-news/hundreds-fall-ill-after-having-swine-flu-jab-1974224.html

Swine flu vaccine has caused adverse reactions in 619 people to date, varying from seizures and anaphylactic shock to fainting and vomiting.

Two more people have died from the flu but the number of people falling ill with the virus has halved in the past week.

More than 400,000 vaccinations against swine flu have been carried out, according to the latest figures from the Irish Medicines Board which details the reported side effects for both forms of the vaccines -- Pandemrix and Celvapan.

Of the 619 people who showed side effects to the vaccine, 52 had an allergic reaction and three of these went into anaphylactic shock.

Altogether 210 children reacted adversely to the vaccine, 15 with an allergic reaction and some of the children needed hospital treatment as a result.

Forty pregnant women reported side effects, four of them allergic and one woman, with a history of miscarriage, lost her baby.

Six people had seizures, two people reported facial palsy and the IMB was made aware of the death of one patient 10 days after vaccination but says the patient had an underlying condition and there was no evidence of a link between the vaccine and the patient's death.

"Most people receiving the vaccine have serious and/or chronic underlying medical conditions which put them at greater risk of developing serious complications of swine flu," says the board adding "this is why it is important for these people to be vaccinated as a priority".

Generally the reactions included flu-like illness, head-ache, dizziness and fainting, pins and needles, transient weakness of the vaccinated limb and nausea and vomiting.

The latest people to die from swine flu were two men with underlying illnesses, one from the east and the other from the south of the country, bringing the total deaths to 20.

Health officials say there has been a marked decline in the spread of the virus in the past week, down to 5,500 new cases compared to 10,500 the previous week.

Témoignages d'effets indésirables violents

AgoraVox, 14 décembre 2009
https://www.agoravox.fr/actualites/sante/article/vaccination-h1n1-cascade-de-66654

C'est bien connu: les effets indésirables des vaccins contre la grippe A/H1N1 sont dérisoires, une petite démangeaison locale, quand il y en a. D'ailleurs le gouvernement en est tellement persuadé qu'il vous fera signer une décharge avant la piqûre. Tellement persuadé, que les laboratoires bénéficient d'une immunité juridique. Avez-vous entendu parler d'effets indésirables violents suite aux vaccinations, au sacro-saint journal de 20h? Moi pas. Et ne pas aborder le sujet, c'est laisser entendre qu'il n'y a pas matière à disserter.

Pourtant, la réalité du terrain est bien différente. Si la plupart des vaccinations se passent, pour l'instant, correctement, les couacs commencent à se multiplier et certains d'entre eux sont peu rassurants. Pour l'instant, car le squalène, utilisé dans la guerre du golfe, qui a provoqué une hécatombe dans les rangs américains plusieurs années après avoir été administré, pourrait refaire parler de lui (0). Mais, même en se focalisant sur l'instant, la vérité commence à prendre forme.

Car, outre le doute sur le vaccin lui-même, vient s'ajouter la véritable débandade dans l'organisation de la campagne. En regard des personnels de santé non formés et réquisitionnés manu-militari, ce sont les conditions de vaccination qui commencent à être mises en causes, des « étudiants qui vaccinent sans autorisation », parfois sans médecin qui supervise, et à la chaîne – jusqu'à 600 vaccinations par jour et par étudiant : « De plus en plus de cas d'accidents, de patients qui reçoivent des surdoses, remontent à mes oreilles. Car ce ne sont pas les mêmes étudiants qui préparent le vaccin (mélange d'une base et d'un adjuvant) et ceux qui l'administrent. Or le vaccin n'est pas le même pour tous!», rappelle Thierry Amouroux, secrétaire du Syndicat national des professionnels infirmiers (SNPI). (1)

Un vaccin douteux, des novices réquisitionnés, acculés dans les centres à coup de chantage administratif, qui manient la seringue à la manière des «temps modernes» de Charlie Chaplin, que peut-il sortir de bon de cette foire du trône médicale? Qu'on en juge:

«je me suis faite vaccinée par pandemrix le 1er décembre, dans les deux jours qui ont suivis, rien si ce n'est la douleur dans le bras, le 3e jour reveil 3/4 h après m'être endormie par des tremblements et l'insensibilité de mes pieds jusqu'aux genoux. En totale panique j'ai appelé le 15 qui m'a dit d'attendre et de rappeler si cela persistait, dans la foulée j'ai eu la diarrhée et depuis ça va de mal en pis, je ne dors plus j'ai une douleur dans la poitrine. J'ai consulté et attend mes résultats sanguins ce soir, je pense que suivant cela je me rendrais aux urgences car je ne me sens vraiment pas bien.» (2)

«Je suis médecin hospitalier, à ce titre j'ai fait parti de la 1ère vague de vaccinations. Et bingo, 3 jours aprés l'injection, je me suis trouvé être l'un des 4 premiers patients à avoir un effet indésirable grave. "homme de 34 ans, avec paresthésies..." d'aprés l'Afssaps. Je vous épargnerai les détails, mais bilan des courses: 1ère poussée de sclérose en plaque, et déjà un mois d'arrêt de travail». (3)

«Samedi 21 novembre, j'ai commencé à sentir des sensations anormales dans ma main gauche: picotement, engourdissement, froid. Ensuite se fut le tour de tout mon bras gauche puis le droit, ce qui m'a conduit lundi 23 novembre, à me rendre chez mon médecin traitant avec 2 bras complétement

engourdis et des fasciculations sur tout le corps (myokimies m'a précisé le médecin). Mon médecin traitant m'a dirigée, en suspectant un syndrome de Guillain Barré sur le service de médecine interne de l'hôpital le plus proche pour rencontrer le médecin chef de service. Lorsque je me suis présentée dans le service, celui-ci a pris moins de 2 minutes dans les couloirs pour me dire de revenir vendredi 27.... » (4)

«je suis très inquiète, ma soeur s'est faite vacciné dimanche dernier avec pandemrix, une heure après elle a ressenti comme un enorme mal de tete et dès le lendemain des fourmillements sont apparus dans les bras et les cuisses, les pieds, le visage... 3 jours apres ayant toujours des fourmillements, le centre de vaccination lui conseille de se rendre aux urgences lui informant que son état n'etait pas normal. Aujourd'hui vendredi nous en sommes là : toujours des fourmillements et quelques maux de tête ..... mais surtout une inflammation au cerveau (lésion) datant de moins de 2 mois, nbre de ???? élevé à 4 après ponction lombaire donc il y a une inflammation et on doit lui faire un irm de la moelle epinière au cours du week end..... Le médecin ne nie pas le lien avec le vaccin, une déclaration va être faite mais aucun résultat ne peut le prouver. Elle a 32 ans et n'avait jamais eu ce type de symptome precedement. » (5)

«Bonsoir, alors voilà vaccin fait pour moi et mon fils hier soir à 17h44 lol pour être précise avec le vaccin Celtura, hier aucun problème, aucune douleur ni pour mon fils, ni pour moi. Ce matin 5h30 mon fils se réveille m'appelle je vais le voir il venait de vomir dans son lit et me disait avoir très mal, je le touche il était plus que brûlant! Je lui change son lit, lui apporte une poche de glace enroulée dans un linge, je lui donne du frais à boire, j'essaye de lui faire prendre de l'algifor en sirop mais il a refusé, impossible de lui faire avaler, je prends sa température 39,9 c° alors qu'il allait parfaitement bien en allant se coucher. Bref nuit catastrophique, il dort à moitié tous en gémissant par moment et en parlant mais genre hallucination il me disait qu'on était chez le médecin alors qu'on était à la maison, bref il n'allait vraiment pas bien, j'ai été cherché mon duvet, mon oreiller et je suis restée près de lui toute la nuit à dormir parterre au pied de son lit (enfin dormir quelques minutes, se réveiller, et ainsi de suite.) Ce matin 8h40 il se réveille vraiment, mais il n'arrive pas se lever comme les jambes en coton, à peine il voulait se lever il retombait, j'ai appellé la hotline d'urgence pédiatrique (urgence je sais qu'ils sont débordés mais quand même, plus d'1h pour pouvoir les atteindres...) car toujours 39c° de fièvre et justement il restait couché en plutôt plié en deux en me disant qu'il arrivait pas se lever et qu'il avait sommeil. » (6)

«Durant la nuit de lundi à mardi, j'ai eu beaucoup de fièvre. Je me suis réveillée avec mon bras gonflé. Je ne pouvais plus le bouger ». Résultat, une semaine d'arrêt pour la jeune fille et des regrets: « Si j'avais su, je ne me serais jamais fait vacciner. Les patients ne sont pas prévenus que de tels effets peuvent arriver ». Avertie par plusieurs de ses patients, la doctoresse de l'étudiante décide de ne plus les envoyer se faire vacciner. (7)

«J' ai été vacciné y a 15 jours et j' ai eu très mal au bas du dos pendant 8 jours (sacrum déplacé car parti plus faible de mon corps).Ma femme est vacciné depuis hier et se retrouve au lit avec le dos deglingué» (8) […]

Ces témoignages français peuvent être multipliés à volonté, il suffit de parcourir les très nombreux forums qui en parlent, et on peut faire la même chose pour tous les pays. Aux Etats-Unis, par exemple, c'est le triste témoignage de la CheerLeader (9), qui a perdu l'essentiel de ses capacités motrices après la vaccination, qui défraye la chronique. En Hollande, un vaccin a été retiré après la mort de 3 bébés. (10)

En lisant les témoignages, on s'aperçoit qu'il n'existe aucune procédure de déclaration d'effets secondaires. Comment donc l'Afssaps peut-elle prétendre établir des statistiques, si seule une fraction de cas flagrants lui parvient ? Les patients sont livrés à eux-mêmes, et l'administration médicale traîne la savate à reconnaître un lien entre les effets indésirables et la vaccination récente. Comme les effets secondaires neurologiques (11), cette femme enceinte qui a perdu son bébé (12), ou cet enfant de 9 ans, décédé 4 jours après s'être fait vacciné (13). On comprend mieux le doute qu'avait évoqué le Dr Girard sur la validité de la pharmaco-vigilance.

Compte tenu de cette inertie administrative à reconnaître et répertorier les effets indésirables, les multiples signalements de décès à travers le monde, 55 reconnus officiellement à ce jour (14), ainsi que les effets indésirables graves, sont probablement très en dessous de la réalité. Quand on voit que le CDC admet qu'il y a deux fois plus d'effets indésirables que pour la grippe saisonnière, et que le taux d'effets pour le H1N1 est de 82 pour un million (15), ça laisse sans voix. En effet, l'Afssaps, qui ne bénéficie d'aucune ressource de suivi de terrain, parle déjà de 0,5 effet indésirable sur mille (16), cad 500 pour un million.

En clair, les Etats-Unis ont … 6 fois moins d'effets indésirables que la France. De deux choses l'une, soit la France a acquis de la daube auprès des laboratoires, soit les autorités médicales américaines sont encore plus complaisantes que les nôtres en matière de rapport statistique. A qualité égale de vaccin, et à honnêteté statistique égale, c'est 6 fois plus d'effets indésirables américains qui auraient dû figurer dans la presse internationale, ce qui aurait (ramené au chiffre de la population américaine) dissuadé la plupart des gens d'aller se faire vacciner. Tout cela pour un taux de mortalité qui aura eu le record du grotesque dans l'histoire de la médecine: 0,03 pour mille, 30x moins que la grippe saisonnière.

THE FLU CASE

Reports of serious side effects for Swine Flu jab sore in France
Only Internet Reports

The Flu Case, 15 December 2009
https://web.archive.org/web/20100102053140/http://theflucase.com/index.php?option=com_content&view=article&id=2299%3Areports-of-serious-sude-effects-for-swine-flu-jab-soar-in-france-only-internet-reports&catid=1%3Alatest-news&Itemid=64&lang=en

Reports of serious side effects from the swine flu vaccine including numbness, fever, inflammation of the brain are soaring in France - but in a pattern that is repeating itself across the world, the reports are being ignored by the authorities and the mainstream media, and are instead being circulated on the internet.

One hospital doctor who was among the first to get the jab reported he had serious side effects within three days. Another physics teacher reported that all five of the children in a class who got the jab have been absent for a week.

Several people get GBS after swine flu vaccinations, yet some doses 'not potent enough'

Examiner, 15 December 2009, 4:14 PM MST
https://web.archive.org/web/20150210114455/http://www.examiner.com/article/several-people-get-gbs-after-swine-flu-vaccinations-yet-some-doses-not-potent-enough

Several people have reported suffering from symptoms of paralysis, muscle spasms, weakness and numbness in limbs after receiving swine flu vaccinations in the US and in other countries. Symptoms of dizziness and paralysis occurred right after vaccination for a 16-year-old boy in Korea. But for others, some of which were in the US, the onset was anywhere from a few hours to a week after vaccination, according to a www.wnd.com article.

Cases in Tennessee, Virginia and New Mexico (one in each state) were cited in the article and included an adult a teen and a 14-month-old girl. Outside the US, a case in France, Canada and Korea were mentioned.

Guillain-Barre Syndrome (GBS) is basically a nerve disease and symptoms can include "paralysis, inability to breathe, 'pins and needles' sensations in fingers and toes; weakness or tingling in legs and upper body; inability to walk; difficulty with eye movement, facial movement, speaking, chewing or swallowing; severe lower back pain; difficulty with bladder control or intestinal functions; very slow heart rate or low blood pressure; difficulty breathing; choking on saliva and even complete paralysis of legs, arms and breathing muscles over the course of a few hours."

The Tennessee adult who contracted GBS, Suzanne Hogan, was hospitalized on November 14 when "she lost function of her legs and was unable to walk without assistance. She is now learning how to master motor skills." Hogan's husband stated that they have been told that she will recover but that, "If you've ever watched anyone go through Guillain-Barre, you would rather go through the flu."

The US teen is also expected to fully recover, but detail was not offered concerning the 14-month-old.

Interestingly, www.foxnews.com reported Tuesday that 800,000 doses of swine flu vaccine intended for children between the ages of 6 months and about 3 years are thought to "not be potent enough to protect against the virus," and that "Health officials recommended children those ages get two doses, spaced about a month apart."

Apparently, the pre-filled syringes tested fine for potency just before shipping, but then the potency waned. Further explanation about how potency can wane during shipping wasn't offered. The vaccine manufacturer, Sanofi, has commented that there aren't any safety concerns associated with the lots.

The swine flu vaccine was fast-tracked through the FDA process because swine flu had been determined to be a pandemic by the WHO. As of December, it was discovered that swine flu is not as serious as originally anticipated, and Harvard University researchers concluded that it is only slightly worse than the seasonal flu. As a result, public interest in the vaccine is waning in some states, one of which is Ohio. CDC spokesman Tom Skinner has stated that there could be several

states across the US that have a surplus while other states have a shortage, but that it's too early to be certain about supply and demand issues.

One might also find it interesting to note that this particular discovery of the swine flu vaccination is being reported during the same week that Senator Lieberman is being accused of holding up the passage of the liberal Democrat Senators' healthcare bill. In reality, of course, there are several moderate Democrats who have taken issue with certain aspects of the bill, and the Republicans are united in stopping its passage. Those who are opposing the bill are more in touch with what the majority of Americans want than those who are trying to ram it through based on polls about the healthcare bill. And those in congress are supposed to be developing legislation that reflects the will of the majority of American people, not their own will.

The passage of this anti-healthcare bill and of the economically destructive cap and trade bill will certainly bring us one step closer to a one world system (see Revelation chapter 13, Matthew chapter 24, and the Old Testament book of Daniel chapter 9 verses 20-27). To be a bit more specific concerning the one world system (or new world order), this will look like a one world government (with a small elite class where everyone else lives in poverty), a one world communistic leader, one world currency, and one world religion, which will basically consist of worshiping the one world communistic leader. It's not going to be some utopia. In fact, it won't even be remotely close to what life is presently like in America with the freedoms that we presently enjoy.

Poverty and joblessness will be far more rampant as people begin to depend more and more on a system that continues to enslave them. That's why becoming engaged in the political process and taking the time to vote out officials who are in this for their own gain rather than what's truly best for the country is so important – especially come 2010.

Is H1N1 Vaccine linked to rare Disorder?
Kansas man afflicted with Guillain-Barre Syndrome

KMBC News, 18 December 2009
https://www.youtube.com/watch?v=xCPYc0BlGW0

Overland Park, Kan. - A 73-year-old Atchison man is in the hospital, unable to stand on his own because his muscles are too weak, and his family is concerned about the H1N1 flu vaccine he received.

Health officials said they doubt the family's claim, but they admit they don't know what is causing the man's affliction. – "I was in fine shape Friday evening," Gerald Kuckelman told KMBC's Jim Flink. "I got up Saturday morning, and I couldn't walk."

"I got up Saturday morning, and I couldn't walk."

It wasn't a stroke or a heart attack. His doctors said the muscle weakness is from Guillain-Barre Syndrome, a rare disorder afflicting only one person in 100,000. – "The doctors haven't said 100 percent that the GB was brought on by the H1N1 vaccine, but I wonder," said Theresa McDermed, Kuckelman's daughter.

Ten days before he was stricken, Kuckelman received the H1N1 vaccine.

Health officials are adamant there is no tie. – "Nowadays, in about 60 percent of GBS cases, we never know what causes it," said Jeff Hershberger, with the Kansas City Health Department.

"Nowadays, in about 60 percent of GBS cases, we never know what causes it,"

Hershberger said with millions of people getting the flu vaccine, only a few patients have reported side effects. The Centers for Disease Control and Prevention is monitoring any cases that arise.

"It's constantly being evaluated, and the CDC is working all the time to decrease the side effects," Hershberger said.

The Kansas City Health Department said concerns about GBS and vaccines dates back to the mid-1970s, but no research has tied the two together.

Krzysztof Tarnawski

Two of 24 influenza volunteers react to locally-made vaccine

MCOT English News, 20 December 2009
http://enews.mcot.net/view.php?id=13354 (deleted)

Bangkok, Dec 20 (TNA) – Two of 24 Thai volunteers to use the locally-made nasal spray vaccine in trials on the Influenza A (H1N1), conducted for the first time in the kingdom, have reacted to the vaccine, Dr. Vichai Chokewiwat, chairman of the Government Pharmaceutical Organization (GPO), on Sunday.

The human trials began Friday, and two of the overall 24 volunteers have already reacted by showing that they suffered from sore throat and swollen noses, said Dr. Vichai. Both had nasal discharges but no fever which showed that their bodies reacted to the vaccine.

In order to ascertain that the volunteers' bodies are immune to the deadly disease, doctors will have to wait for blood test results which will be obtained three weeks after the vaccine was administered, he said.

Dr. Vichai said medical personnel on Monday will check inside the noses of all 24 volunteers, clean them with water and then conduct tests on the water whether it contained any virus from the vaccine. If the virus is found, then it could be proven that the trials were successful.

Such nasal sprays can be harmful for the vaccinated, and can actually contribute to starting a flu epidemic.

Package insert of FluMist, another spray already in use, in part 14.5 reads: "Transmission Study - FluMist contains live attenuated influenza viruses that must infect and replicate in cells lining the nasopharynx of the recipient to induce immunity. The relationship of viral replication in a vaccine recipient and transmission of vaccine viruses to other individuals has not been established."

Prof. Joe Cummins and Dr. Mae-Wan warn that live attenuated viruses from the spray, which contains three strains, can be dangerous as they have potential to recombinate nucleic acids and cause autoimmune disorders. Dr. Rima Laibow and others point out, that introducing viruses via olfactory track may result in viral brain inflammation and its damage. What is more, safety of the spray has not been evaluated in people with compromised immune system (estimated 60% of the society). This means people can contract illness from the very vaccine and it is just a recipe to trigger an epidemic.

Historically, except for seasonal flu injections bringing severe flu, there are known cases of live vaccines causing illnesses they were supposed to prevent, like the polio outbreaks in Nigeria.

New Thai Nasal Spray Supposed to Spread H1N1

The Flu Case, 20 December 2009 10:21
https://web.archive.org/web/20100102004234/http://theflucase.com/index.php?option=com_content&view=article&id=2346%3Anew-thai-nasal-spray-supposed-to-spread-h1n1&catid=1%3Alatest-news&Itemid=64&lang=en

Thailand is testing a new H1N1 nasal spray on volunteers. The article quoted below first mentions blood test after three weeks, but later informs that if on day three after vaccine application nasal discharges with the virus are present, this is supposed to indicate the trials were successful.

Mandatory autopsies sought for suspected vaccine fatalities

The China Post, 24 December 2009, 9:28 am
https://web.archive.org/web/20091227072533/http://www.chinapost.com.tw/taiwan/national/national-news/2009/12/24/237785/Mandatory-autopsies.htm

(The China Post) **Taipei**, Taiwan – Taiwan's Center for Disease Control (CDC) yesterday announced a plan to seek an amendment to the Disease Prevention Act to allow for mandatory autopsies on all vaccine-related deaths. The amendment would allow health authorities to perform autopsies to find out the exact cause of death on fatalities involving recent inoculations, to alleviate any public fear on the safety of the vaccinations, explained Chou Jih-haw, CDC deputy director-general.

The plan comes after the controversial death of a 7-year-old boy who received a vaccination against the A(H1N1) virus. According to CDC statistics, the center received 93 reports of severe adverse reactions to the vaccination, of which four proved fatal, while five pregnant women suffered miscarriages or stillbirths.

However, obligatory autopsies can only be performed on one of the fatalities because it is the only one under judicial investigation.

Currently, mandatory autopsies apply only to deaths involving infectious diseases, but not to deaths allegedly related to vaccinations – resulting in uncertainty over what exactly caused the deaths.

If the amendment is passed by the legislature, mandatory deaths will apply to all suspected inoculation related fatalities, regardless of the type of vaccination received, added Chou.

The Korea Times

292 Cases of Flu Vaccine Side Effects Reported

The Korea Times, 25 December 2009, 21:24
https://web.archive.org/web/20091231021941/http://www.koreatimes.co.kr/www/news/nation/2009/12/117_57965.html

A total of 292 possible side effects have been reported after vaccinations against the H1N1 virus here, so far, the Ministry for Health, Welfare and Family Affairs said Thursday. The majority of reactions have been minor and assumed to be unlinked to the vaccine.

"There have been four deaths and three critical reactions reported after inoculation. However, it was later found that the three deaths and the illnesses have stemmed from pre-existing health conditions. The authorities are currently conducting an autopsy on a 19 month-old infant's body, of which the result is expected to come next week," a government official said.

The ministry also said the spread of the virus was slowing down here.

The World Health Organization said that 11,516 people worldwide have died of the flu as of Dec. 20, up 934 from the previous week. Most deaths have been in America, with 6,670 fatalities, followed by Europe and the Asia-Pacific region.

WHO said the transmission of the virus has passed its peak in the northern hemisphere, but is still active in east Europe and some parts of southern Asia.

EUROPEAN MEDICINES AGENCY
SCIENCE MEDICINES HEALTH

EMEA Massages Swine Flu Vaccine Adverse Reactions Statistics

The Flu Case, 29 December 2009, 12:24
https://web.archive.org/web/20100102054535/http://theflucase.com/index.php?option=com_content&view=article&id=2426%3Aemea-massages-swine-flu-vaccine-adverse-reactions-statistics&catid=1%3Alatest-news&Itemid=64&lang=en

The European Medicines Agency – which is two thirds funded by the pharma industry according to Transparency International – has published a summary of adverse reactions to the swine vaccines and Tamiflu in Europe up to 13 December 2009.

The Fourth pandemic pharmacovigilance weekly update of reports of adverse reactions up states that "the most frequent adverse reactions that have been reported are non serious and as expected."

It says that 28 million people in Europe have been vaccinated so far.

From the "limited information received from 7 countries by 22 December 2009, at least 218 pregnant women have been vaccinated."

It admits that 13 cases of Guillian-Barre syndrome (GBS) and 1 case of Miller-Fischer syndrome in relation to the vaccines have been reported but claims there is evidence that these cases were caused by the vaccine. It argues that these 13 cases are lower than the overall number of cases expected to naturally occur.

However, medical experts have made a clear connection between the swine flu vaccines and GBS, and the UK government even sent neurologists a letter warning them of the likelihood of an increase in GBS cases as a result of the mass swine flu vaccination programme.

To argue that the 13 cases are just part of the overall number of cases expected to occur naturally strongly suggests the notion that the EMEA is more interested in white washing the pharmaceutical industry than in fulfilling its duties.

Hundreds of deaths in connection with the vaccine have been reported to national regulatory agencies in Europe alone.

the japan times

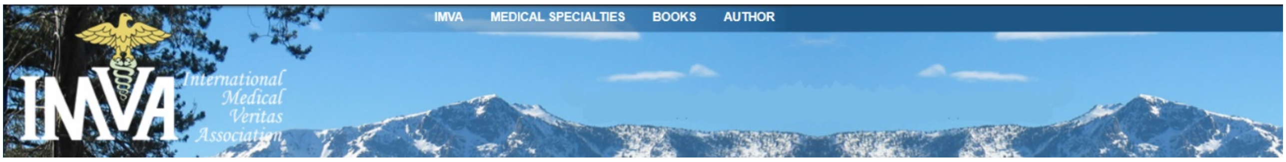
H1N1 vaccine death probe set

The Japan Times, 31 December 2009

http://www.japantoday.com/category/national/view/health-ministry-to-investigate-link-between-deaths-flu-vaccination (deleted)
https://web.archive.org/web/20100220012002/http://www.theflucase.com/index.php?option=com_content&view=article&id=2454%3Ajapan-to-launch-investigation-into-swine-flu-vaccine-deaths&catid=41%3Ahighlighted-news&Itemid=105&lang=en

The health ministry will conduct an epidemiologic investigation into whether H1N1 influenza vaccinations can increase the death risk for people with serious chronic diseases, ministry officials said Wednesday.

The Ministry of Health, Labor and Welfare plans to begin the study next spring amid an increasing number of reports of deaths and serious side effects among the people who have received shots of domestically produced vaccines against the virus.



The ministry said postvaccination deaths have totaled 104, roughly 80 percent of whom are people aged 70 or older who had chronic diseases or disorders, while nearly 1,900 cases of side effects had been reported from medical institutions.

It estimates 14.92 million people have been vaccinated so far nationwide.

Swine Flu Madness

IMVA, October – December 2009
https://web.archive.org/web/20100127000050/http://imva.info/index.php/vaccines/swine-flu-madness/

Under federal laws adopted post 9/11, the Secretary of HHS candeclare a national emergency and order all citizens to be vaccinated.These extreme powers can permit agents of the federal government to enterprivate residences to compel those inside to receive vaccinations.[1]
Jonathan W. Emord
Attorney of constitutional and administrative law

More than a third of parents don't want their kids vaccinated, according to an Associated Press-GfK poll yet public health officials seem ready to ram it down their throats if possible. Parents say they are concerned about side effects from the new vaccine and many say swine flu doesn't amount to any greater health threat than seasonal flu. The AP poll found that 38 percent of parents said they were unlikely to give permission for their kids to be vaccinated at school. The AP poll, conducted Oct. 1-5, found 72 percent of those surveyed are worried about side effects.[2]

Health and Human Services Secretary Kathleen Sebelius appealed for widespread inoculation against swine flu, vouching unconditionally for the vaccine: "We know it's safe and secure." This official has what can only be considered as Swine Flu Madness for she really does not know if it's safe and secure. In fact she has to know that a warning that the new swine flu jab is linked to a deadly nerve disease has been sent by the Government to senior neurologists in a confidential letter. The letter from the Health Protection Agency, the official body that oversees public health tells the neurologists that they must be alert for an increase in a brain disorder called Guillain-Barre Syndrome (GBS),[3] which could be triggered by the vaccine. GBS attacks the lining of the nerves, causing paralysis and inability to breathe, and can be fatal. The letter, sent to about 600 neurologists on July 29,[4] is the first sign that there is concern at the highest levels that the vaccine itself could cause serious complications yet Sebelius and others are on their bullhorns telling the public it is safe.

More than half a million U.S. children yearly havebad reactions or side effects from widely used medicinesthat require medical treatment and sometimes hospitalization.[5]

U.S. health officials have lost track of how many illnesses and deaths have been caused by the first global flu epidemic in 40 years. And they did it on purpose. Government doctors stopped counting swine flu cases in July.[6] Yet at the same time we find at a recent CDC weekly meeting on swine flu, Anne Schuchat, MD, Director of the CDC's National Centre for Immunization and Respiratory Diseases, informed of the increasing illnesses, hospitalizations, and deaths, virtually all due to the H1N1 virus. To date, 37-states have reported cases of swine flu, with 19-paediatric deaths reported last week, which means 76-children have died of swine flu this year, many more than the typical influenza toll in the past years. According to CDC, between 30th August and 3rd October, 1,784-American adults and children have died from pneumonia or different strains of influenza.[7] Health officials seem to be confused; are they counting or not?

Fortunately, we have some heroes standing up to the might of the vaccine industry and public health officials. Mike Adams over at Natural News reports that health freedom attorney Jim Turner is

filing a lawsuit in Washington D.C. mid-day Friday in an urgent effort to halt the distribution of the swine flu vaccine in America. On behalf of plaintiffs Dr. Gary Null and other licensed health care workers of New York State, the lawsuit charges that the FDA violated the law in its hasty approval of four swine flu vaccines by failing to scientifically determine neither the safety nor efficacy of the vaccines. "The suit will seek an injunction against the FDA from approving the vaccine and the core of the argument is that they have not done the proper safety and efficacy tests on the vaccine to allow it to be released at this time," attorney Jim Turner told Natural News.[8]

The World Health Organization (WHO) restated its confidence in the H1N1 flu vaccine on October 6th, calling it the most important tool against the pandemic though they admit that mild adverse side effects such as muscle cramps or headache are to be expected in some cases, but everyone who has access to the vaccine should be inoculated the WHO said. Of course, they don't mention the possibility of serious side effects including death.

As soon asswinefluvaccinationsstart next month, some peoplegetting them will drop dead of heart attacks or strokes, somechildren will haveseizuresand some pregnant women will miscarry.

New York Times [September 28, 2009].

A majority of doctors and medical examiners are notoriously prone to gloss over the official cause of death when mortality occurs in close proximity to vaccine administration. It is not surprising that the WHO recommends the vaccine even to pregnant women for the WHO is a front organization for one world government, which obviously could care less if fetuses are contaminated. Officials are worried about spontaneous miscarriages, because they are urging pregnant women to be among the first to be vaccinated even though most of the vaccines contain thimerosal, which is fifty percent methyl mercury by weight.

Any competent biochemist would look at the structure ofthimerosal and identify it as a potent enzyme inhibitor.What is surprising is that the appropriate animal and laboratory testing was not done on the vaccines containing thimerosal (and aluminum)before the government embarked on a mandated vaccine program thatexposed infants to the levels of thimerosal that occurred.

Dr. Boyd E. Haley

Yet today we find the New York Times giving space to Dr. Paul A. Offit who says, "Infants could safely receive eight times as much mercury as is contained in the H1N1 vaccine."[9] Dr. Haley, former chairman of the chemistry department of Kentucky University is one of the most intelligent and noble men I have ever had the pleasure to talk to. One can hardly say that about Offit who has financial stakes in the vaccine industry.[10]

Doctor admits Vaccine is more deadly than Swine Flu itself & will not give it to his kids

Fox News

Why would you sign a consent form for your children to be injected with mercury, which is 100 times more brain-toxic than lead? And why would your government want you to do so? Pregnant women and their fetuses are especially sensitive to mercury and mercury has been established by the federal vaccine court to be associated with autism in cases where the children had mitochondrial disease. Problem is doctors and nurses have not the slightest idea which children have such metabolic disorder before they inject their little patients with so many vaccines it would turn grandma's hair white if it wasn't already.

Documents from the archives of Eli Lilly & Companyclearly demonstrate that it was known as early as April 1930 that the thimerosal was dangerous.

The following is a list of some of the nasty side effects that the package insert for the Influenza A (H1N1) 2009 Monovalent Vaccine manufactured by Novartis admits to: [11]

*Local injection site reactions (including pain, pain limiting limb movement, redness, swelling, warmth, ecchymosis, induration); *Hot flashes/flushes; *Chills; *Fever; *Malaise, *Shivering; *Fatigue; *Asthenia; *Facial edema; *Immune system disorders; *Hypersensitivity reactions (including throat and/or mouth edema); *In rare cases, hypersensitivity reactions have lead to anaphylactic shock and death; *Cardiovascular disorders; *Vasculitis (in rare cases with transient renal involvement); *Syncope shortly after vaccination; *Digestive disorders; *Diarrhea; *Nausea; *Vomiting; *Abdominal pain; *Blood and lymphatic disorders; *Local lymphadenopathy; *Transient thrombocytopenia; *Metabolic and nutritional disorders; *Loss of appetite; *Arthralgia; *Myalgia; *Myasthenia; *Nervous system disorders; *Headache; *Dizziness; *Neuralgia; *Paraesthesia; ***Febrile convulsions;** ***Guillain-Barré Syndrome;** *Myelitis (including encephalomyelitis and transverse myelitis); *Neuropathy (including neuritis); *Paralysis (including Bell's Palsy); *Respiratory disorders; *Dyspnea; *Chest pain; *Cough; *Pharyngitis; *Rhinitis; *Stevens-Johnson syndrome; *Pruritus; *Urticaria; *Rash (including non-specific, maculopapular, and vesiculobulbous).

GlaxoSmithKline won a further 22 government orders for its H1N1 swine flu vaccine in the last two months, taking the total number of doses ordered to 440 million worth some $3.5 billion. Rivals in flu vaccines include Sanofi-Aventis, Novartis, Baxter, AstraZeneca and CSL. The President's Council of Advisors anticipates that 2009 H1N1 may infect half of the US population, require 1.8 million hospitalizations, and result in 30,000-90,000 deaths[12] but it is not clear whether the virus or the vaccines themselves will be the major cause of what they are anticipating. Considering the fact that the swine flu has been very mild we can easily believe that the vaccines themselves will do the dirty work.

I have run against so many histories of little childrenwho had never seen a sick day until they were vaccinated and who,in the several years that have followed, have never seen a well day since.I couldn't put my finger on the disease they have.They just weren't strong. Their resistance was gone. They were perfectly well before they were vaccinated.They have never been well since.

Dr. William Howard Hay

Dr. Hay is not alone and its public knowledge that tens of thousands of health care workers typically avoid flu shots because of questions of safety and effectiveness. Fewer than half of them got flu vaccinations last year, according to a Centers for Disease Control and Prevention survey. That includes physicians in clinics, lab technicians, respiratory therapists and home health aides.

Approximately one-half of the hundreds of parentswho call our office each month report that their childbecame autistic shortly after receiving a vaccination.

Portia Iverson, Cure Autism Now foundation in Los Angeles

The official advice on swine flu protection is essentially limited to "wash your hands, get your vaccine shot and cough into your elbow. The omission of vitamin D (among many other things) is another demonstration of pharmaceutical and medical terrorism. The officials we pay and trust could care less if we die from the flu or flu shot, in fact our deaths substantiate their theories and marketing campaigns. The simple addition of vitamin D supplementation or recommendations to get healthy doses of sun and vitamin C would go a long way, longer than the vaccines to mitigate death from the flu. So would recommendations to doctors and patients to fully hydrate. Yesterday I received a testimonial[13] of the use of hydrogen peroxide and in addition to the IMVA protocol [14] for Swine Flu treatments.

Utter Criminal Madness to Use Thimerosal in Vaccines

Robert F. Kennedy Jr. published in the Huffington Post a few years ago devastating evidence that implicated the CDC in a terrible scandal in regards to the unnecessary injection of millions of children with thimerosal a few years back and this is important because again the CDC is going to

allow mercury containing thimerosal to be used in the swine flu shots as well as the regular flu shots in the fall of 2009.

Correspondence obtained under the Freedom of Information Act reveals a medical monstrosity at the very center of the medical world. Soon after the CDC in July 1999 recommended that the nation's vaccine makers eliminate Thimerosal as a preservative, "as soon as possible," they themselves (the CDC) secretly discouraged Thimerosal removal in effect deliberately exposing millions of infants to continued mercury poisoning.

According to Kennedy, in a July 1999 letter, vaccine producer SmithKline Beecham tells CDC that it is ready to produce non-Thimerosal DTP (Diptheria/Tetanus/Pertussis) vaccines immediately and has sufficient inventories to supply the entire U.S. market during the remainder of 1999 and the first half of 2000, by which time other vaccine manufacturers would have their Thimerosal-free DTP vaccines on line. Thimerosal-laden DTP vaccines containing 25 micrograms of mercury apiece (75 thousand trillion atoms of mercury) were then being administered to American infants at two months, four months and six months – far exceeding EPA's recommended safe level for mercury. Had CDC accepted SmithKline's offer, it could have immediately reduced the mercury exposures to vaccinated six-month-old children by 40%.

Kennedy continued, "However, in November, CDC mysteriously sent a letter back rejecting Smith Kline's offer. Then, on July 14, 2000 CDC published a deceptive press release promising to require that all vaccines be Thimerosal-free as soon as "adequate supplies are available." This was a full 12 months after the agency had denied SmithKline's proposal."

I devoted time to study this issue because I believe that this is a moralcrisis that must be addressed. If, as the evidence suggests, ourpublic-health authorities knowingly allowed the pharmaceutical industryto poison an entire generation of American children, their actions arguablyconstitute one of the biggest scandals in the annals of American medicine. Robert F. Kennedy, Jr.

"If CDC were basing its decision on safety alone, it would have taken SmithKline up on its offer. That's a no-brainer," said a federal health official to Kennedy anonymously. "So there were other considerations beside safety that were guiding their decision making." "Among these "other considerations" were CDC's important concerns for the preservation of the vaccine program, a bureaucratic impulse for self-preservation, and protecting the economic interests of its vaccine industry friends."Immediate withdrawal would send a strong message; 'We messed up!'" the health official told Kennedy. "And I don't think they wanted to send that message to parents, the public or those considering legal action." "There was also concern," says the federal official, "that an immediate withdrawal might discredit the international vaccine programs for which CDC is an important partner."

Why will CDC inject millions of minority kids in America's poorestneighbourhoods with poison proven to kill brain tissue and causelearning disorders when child-safe vaccines are available?

Robert F. Kennedy Jr.

[13] I wanted to share my testimony with you about MY recent flu episode (this past week). Last Sunday I had a very scratchy throat and started feeling achy. I was on a lovely drive with 2 friends to the mountains to get fresh apples at warehouses along Hwy. 16 up past Taylorsville, NC. We stopped for a nice lunch on the way home and my throat was getting so sore eating was barely enjoyable, despite delicious food. By the time we got back to my house I was starting to feel feverish and had a pretty severe headache… so I immediately drank a pint of water and went to bed… where I STAYED (except hours. Wallah! A book I got from my dad after he died in 2001 surfaced and saved the week for me: Dr. William Campbell Douglass book: Hydrogen Peroxide: Medical Miracle. I immediately staggered to my vitamin cabinet and dragged out the bottle of Food Grade H2O2 I had squirreled away many years ago… put 1/4 tsp in a pint of water, swished it around my mouth, gargled, then swallowed the first half, then drank the rest. Back to bed and finally some sleep. When I awoke the massive headache was almost gone, the all-over body aches were drastically less and my throat was not killing me. The runny nose and dry cough even subsided dramatically! So I have been drinking 10 drops to 1/4 tsp H2O2 in a pint of water as often as possible for the past day and a half and I feel back to "normal" now (whatever normal is). I've been a health coach since 1968 and had not been sick in over 10 years, so this whole episode took me my complete surprise. I tried massive C, homeopathic medicines, essential oils, oregano oil and nothing much worked… but the 35% Hydrogen Peroxide in water really sent those nasty bugs that had hold of my body … into a tailspin down the drain! I now have two new 16 oz. bottles of peroxide in my cupboard and am using it regularly – even to brush my teeth 2xday and soak my dental piece every night. / Jan Jenson

男人流感疫苗注射後被給五萬新台幣
Man given NT$50,000 after flu vaccine

The China Post, 2 January 2010, 12:06 am TWN

https://web.archive.org/web/20100118022043/http://www.chinapost.com.tw/taiwan/national/national-news/2010/01/02/238982/Man-given.htm
https://www.discuss.com.hk/viewthread.php?tid=11282775&extra=page=10&nomobile=1

The Department of Health (DOH) decided yesterday to offer a relief fund of NT$50,000 to a 35-year-old man because he showed symptoms including numbness in the lower limbs after getting A(H1N1) flu vaccination, making him the first recipient of financial aid related to the vaccine shots.

Medical experts on a panel screening the medical cases related to vaccination said they have so far reviewed applications for relief fund in 39 cases connected to A(H1N1) flu inoculation, but the man was the only patient qualified for the relief measure.

Commensurate compensation to victimized vaccine recipients will be offered only when three major criteria are met:
1) after they are diagnosed to have suffered consequences related to vaccination;
2) their sufferings have reached a specific extent, and
3) the effects of the vaccines are unable to be ruled out, they explained.

The male patient in the case met the third criterion since the panel was unable to completely exclude the possible impact from the vaccine.

Thirteen days after taking the vaccine shot, the man showed symptoms of fever and numbness in the feet.

Since the man has a medical history of diseases, including problems in spinal cord, the problem could have arisen from effects on his immune system.

He will be given a relief fund of NT$50,000 because the team of medical experts were unable to entirely rule out the connection between the vaccine and the symptoms, a spokesman of the panel said.

The patient is presently recovering from the conditions after follow-up medical treatment, he said.

Families of some patients have held press conferences along with elected officials, mainly lawmakers and members of local county or city councils, to publicly question the connection between the causes of the patients' deaths and the anti-flu vaccine.

They accused the DOH for providing unsafe vaccines and sought government compensation.

At a press conference yesterday, Chang Yao-chung, a member of the Taichung City Council, said a student at a senior high vocational school in the central Taiwan city suddenly lapsed into unconsciousness and died after receiving the vaccine.

There were similar cases and suspicions expressed by patients' families.

DOH officials said autopsies will be performed at the request of families to determine the actual causes of patients' deaths with objective reviews by a panel of medical experts.

But families can also appeal their cases or use other channels for relief if they do not accept the ruling of the panel.

Families of some deceased patients have already filed charges against doctors who provided medical treatment and the DOH for providing the vaccines.

DOH officials such litigation cases will have to be dealt with via proper legal procedures.

Prosecutors said they can proceed with the judicial procedures only after gathering adequate evidence and getting formal medical reports from the Institute of Forensic Medicine under the Ministry of Justice to help determine the responsible parties for the cases.

Officials at the institute confirmed that they have been working on some cases related to the flu vaccines forwarded from prosecutors in various districts to help settle the medical disputes.

But they said the institute will not make public the findings concerning any particular cases before adequate medical examinations and analyses are completed.

AF ALGERIE FOCUS

Vaccin contre la grippe A (H1N1)
Mort suspecte d'un médecin à Sétif, après sa vaccination!

Algerie Focus, 2 January 2010
https://web.archive.org/web/20100103093050/http://www.algerie-focus.com/2010/01/02/vaccin-contre-la-grippe-a-h1n1-mort-suspecte-dun-medecin-a-setif-apres-sa-vaccination/

Gros point d'interrogation. Le vaccin contre la grippe AH1N1 est-il sûr et sans danger comme l'a assuré le ministre de la Santé, de la Population et de la Réforme hospitalière, Saïd Barkat?

Jeudi 30 décembre, soit un jour après le lancement de la campagne de vaccination contre la grippe AH1N1, une terrible nouvelle vient endeuiller le personnel de l'hôpital universitaire Saâdna-Abdennour: le médecin chef du service de réanimation, le docteur Rezig Lilia décède mystérieusement, alors qu'elle «venait de se faire inoculer le vaccin contre la grippe AH1N1, à l'instar de ses collègues» rapport notre confrère Le Jeune indépendant dans son édition du vendredi. La défunte ne présentait aucun signe de maladie qui expliquerait sa mort subite, précise la même source.

Pour rappel, à ce jour 20 cas de grippe A H1N1 suspectés et 4 décès ont été enregistrés au niveau de l'ensemble de la wilaya de Sétif, selon des sources officielles. Néanmoins, depuis la mort suspecte de ce médecin de 35 ans après avoir été vaccinée, d'énormes doutes planent sur l'efficacité, voire la dangerosité potentielle du vaccin.

Interrogé par Le Jeune indépendant, le professeur Lachhab, responsable du centre de référence, indique «qu'il est encore tôt pour se prononcer sur la cause de cette mort subite de sa collègue», et que» seule l'autopsie déterminera la véritable cause de ce décès».

Se voulant rassurant, le professeur Lchahab déclare avoir» été lui-même vacciné du même flacon que la défunte aux côtés du Dr Lehtihet, directeur de la santé, du Dr Koussa, responsable de la cellule de prévention, et d'autres collègues, mercredi dernier, date du début de la campagne de vaccination dans le milieu médical de la wilaya.

THE FLU CASE

Doctor in Algeria Dies One Day after Swine Flu Jab

Algerie Focus // The Flu Case, 15 January 2010

https://web.archive.org/web/20100220012528/http://www.theflucase.com/index.php?option=com_content&view=article&id=2563%3Adoctor-in-algeria-dies-one-day-after-swine-flu-jab&catid=41%3Ahighlighted-news&Itemid=105&lang=en

Vaccine against influenza A (H1N1). Suspicious death of a doctor in Setif after vaccination!

A big question mark. Is the vaccine against influenza AH1N1 as safe as the Minister of Health, Population and Hospital Reform, Said Barkat, affirms?

On Thursday, December 30, one day after the launch of the vaccination campaign against influenza AH1N1, terrible news plunged the staff of the University Hospital-Saadna Abdennour into mourning: the head doctor of the ICU, Dr. Lilia Rezig, had died mysteriously, "just after she had been inoculated with the vaccine against influenza AH1N1, like her colleagues" reported our fellow newspaper "Le Jeune Indépendant" in its Friday edition. The deceased had shown no signs of disease that would explain her sudden death, said the source.

As a reminder, to date 20 cases of suspected influenza A H1N1 and 4 deaths have been recorded at all of the wilaya of Setif, according to official sources. However, since the suspicious death of this 35 year old physician after being vaccinated, huge doubts hang over the effectiveness or the potential dangerousness of the vaccine.

Questioned by Le Jeune Independent, Professor Lachhab, head of the reference centre, said "it is still early to comment on the cause of this sudden death of his colleague," and that "only an autopsy will determine the true cause of this death".

In an attempt to be reassuring, Professor Lchahab said he "was himself vaccinated from the same bottle used for the deceased, alongside Dr. Lehtihet, Health Director, Dr. Kusa, head of the prevention unit, and other colleagues, last Wednesday, date of the start of the vaccination campaign in the medical community of the wilaya.

Fewer swine flu jabs as doc falls ill

The Standard, 8 January 2010
http://www.thestandard.com.hk/news_detail.asp?pp_cat=30&art_id=92850&sid=26627549&con_type=1 – deleted
http://www.whale.to/vaccine/fewer_swine.html

A 58-year-old cardiologist who received a human swine flu (H1N1) vaccination is in serious condition with Guillain- Barre syndrome, a disease that affects the nervous system. But an expert group said it could not be determined if the doctor's disorder was directly caused by the vaccine.

A doctors' group said the case led to a decline in the number of people receiving vaccinations yesterday.

Controller of the Centre for Health Protection, Thomas Tsang Ho-fai, said it is impossible to say whether the man's illness was caused by the flu jab.
"The [expert] group thinks it is not possible to differentiate with reasonable certainty whether the relationship between the vaccine and patient's symptoms is causal or coincidental, meaning that we are unable to conclude one way or the other based on a single case," Tsang said.

"We have vaccinated over 100,000 people in Hong Kong and if we look at overseas experience, the vaccine has not been associated with an increased rate of Guillain-Barre syndrome." He added: "So we are of the view that for high-risk groups the benefit of receiving the vaccine definitely outweighs the risk and we recommend members of such groups to receive the vaccine."

The cardiologist, Kwok Hong-tai, who has an underlying medical condition, received the vaccine on December 24 and began feeling weakness in his lower limbs on December 28, Patrick Li Chung-ki of Queen Elizabeth Hospital said.

Kwok was admitted to Queen Mary Hospital on January 2 where he remained in serious but stable condition yesterday.

A nurse at the cardiologist's clinic in North Point declined to confirm whether the doctor is the one suffering from Guillain-Barre syndrome.

Li said the patient has shown weakness in all four limbs and his symptoms were "compatible with Guillain-Barre syndrome."

The rare disease occurs after receiving vaccines, while other patients develop it after viral or bacterial infections.

For some patients, there is no underlying cause but is "incidental," Li said. Hong Kong Doctors Union president Henry Yeung Chiu-fat said there were significantly fewer people who came forward to be vaccinated at private clinics.

But government figures showed at least 8,872 were vaccinated in the 24 hours ending 1 pm yesterday. Of those, 1,717 went to private doctors, compared with 2,171 the day before.

Infectious disease specialist Lo Wing-lok said the case is more likely related to the vaccine "because of the time sequence and because of various clinical observations and tests done."

He said the case is a "very strong deterrent" for people not to be vaccinated.

Fury at Vaccine Scandal

Express, 10 January 2010
http://www.express.co.uk/posts/view/150804/Fury-at-vaccine-scandal

Hundreds of public sector workers who claim their lives have been wrecked by vaccines say the Government has abandoned them.

Up to 200 doctors, nurses, firefighters, prison officers, police officers, forensic scientists and binmen say they have developed serious physical and mental health problems after injections essential for their work over the past 10 years. All have given up their jobs and some are now 60 per cent disabled.

Last night it emerged they are to miss out on payouts, prompting furore among campaigners. More than 150 MPs have lent their support to demands for a better deal for the victims.

Olivia Price, of the Vaccine Victim Support Group, said: “These people have given their lives in the service of looking after others and this is how they’re repaid. They’ve lost their careers and are a burden to their families. It is very degrading.”

Frontline health workers, social workers, prison officers and binmen have to be vaccinated against hepatitis B as a condition of their employment.

This is to protect them from contracting potentially fatal conditions from infected blood through needle injuries or physical assaults.

Although they are not legally forced to have the vaccinations, without them they are not allowed to work.

Experts believe the injections caused the health problems, which include chronic fatigue, muscle pain, weakness and cognitive problems, because illnesses developed soon after vaccination. In one case Steve Robinson, a previously fit 43-year-old father of three, was vaccinated six years ago against hepatitis A, B and polio, tetanus and diphtheria as part of his work as a forensic specialist.

Two days later he became ill and developed muscle weakness and chronic fatigue. Mr Robinson, from Morpeth, Northumberland, is now 60 per cent disabled, which an industrial injuries tribunal put down to the vaccinations.

He has also been diagnosed with macrophagic myofascitis, a disabling condition which may be caused by the aluminum in vaccines. He also suffers from problems that cause him to fall with no warning. He said: “Before I had the vaccinations I was very healthy, a keen mountain biker and enjoyed walking and keeping fit.

"Now I have very poor mobility and walk with sticks, I am constantly tired." In up to 10 of the 200 cases, Government officials have already ruled, on the balance of probabilities, that the vaccines caused the damage.

Campaigners say these victims should be entitled to payouts of up to £120,000 through the Government's Vaccine Damage Payment Scheme, like other people who have suffered side effects, but the hepatitis B vaccine is excluded so they get nothing.

Payouts are restricted to the industrial injuries scheme but this is a long and difficult process and, according to campaigners, results in "paltry" sums. So far, fewer than 10 have successfully claimed this money. Ian Stewart, Labour MP for Eccles, has tabled an Early Day Motion on the scandal which has been backed by more than 150 MPs of all political parties.

YESHIVA WORLD NEWS

Swine Flu Victim was Vaccinated

The Yeshiva World, 11 January 2010
https://www.theyeshivaworld.com/news/israel-news/44618/swine-flu-victim-was-vaccinated.html

The 66-year-old man who died of swine flu in Tel Aviv's Beilinson Hospital on Sunday did have the vaccination, officials report. Health Ministry officials report that the vaccine takes three weeks from the inoculation date before the recipient is protected and in the case of the niftar, it was less than three weeks since he received the vaccine.

Health Ministry officials fear a new outbreak of the illness, urging citizens to report to their HMO for the vaccination which is now available to the general population.

The updated death toll in Eretz Yisrael from swine flu is now 85.

Panica: Medic decedat la o zi dupa vaccin

România liberă, 15 Ianuarie 2010
https://web.archive.org/web/20100119022035/http://www.romanialibera.ro/eveniment/a174728-plangere-penala-contra-vaccinarii-impuse-de-cercel.html

Potrivit Ministerului Sanatatii, in ultimele 24 de ore s-au mai inregistrat patru decese din cauza A/H1N1 (ajungandu-se in total la 100) si 131 de noi imbolnaviri, pana acum fiind vorba de 6.386 de cazuri.

Un medic de familie din comuna clujeana Alunis s-a vaccinat vineri impotriva virusului A/H1N1, iar sambata a murit. Localnicii, extrem de speriati, spun ca acesta a decedat din cauza vaccinului. Reprezentantii Autoritatii de Sanatate Publica din Cluj sustin insa ca panica este nejustificata, pentru ca medicul a murit din cauza unui infarct. Medicul Mihai Constantin a fost gasit de localnici decedat in curtea casei, iar trupul sau a fost transportat la Institutul de Medicina Legala din Cluj, unde i-a fost facuta autopsia. Potrivit profesorului Florin Stamatian, cadru didactic la Universitatea de Medicina si Farmacie "Iuliu Hatieganu", vaccinul nu are in nici un caz efecte mortale.

Health probe in young man's sudden death

Times Malta, 15 January 2010

Twenty-three-year-old took swine flu vaccine five days earlier

https://www.timesofmalta.com/article/health-probe-in-young-mans-sudden-death.289825

The health authorities are investigating the unexpected death of a young man who took the swine flu vaccine five days earlier, although initial results indicate just a "coincidental" relation between the two.

Clayton Cachia, 23, died on Wednesday evening at Mater Dei Hospital after he was taken ill from work.

Described by his distraught parents, Joseph and Pauline, as perfectly healthy, Mr Cachia was to be engaged to his girlfriend Ebony in two months' time.

The health authorities confirmed that an autopsy was held yesterday and medical tests were ongoing to determine whether the untimely death was related to the vaccine.

"Since the person was injected with the A(H1N1) influenza vaccine five days ago, the case is being followed very closely by the health authorities. From the information collected so far the relation between his death and the vaccine could possibly be coincidental," a spokesman said.

Mr Cachia's sudden death came as a complete surprise to his parents and only sister, Romina.

"He was a healthy six-foot-four boy," his mother said, adding he took the swine flu vaccine on Saturday after being advised to do so at his work place. Mr Cachia had only just started working as a medical representative with a pharmaceutical company two months earlier.

"I do not know whether his death is linked to the vaccine. Doctors said it was not but I don't know. I don't know. I have not taken the vaccine and will not take it myself," his mother added.

"I am going to die," his grieving father said, pointing out that doctors had taken all the necessary tests and sent them abroad.

"They told us his heart swelled. He took the injection on Saturday... I don't know if it was a reaction to the vaccine," he said.

Mr Cachia was an "exemplary" child who, according to his mother, "brightened up the street" with his charm.

An avid Manchester United supporter, Mr Cachia had left home at 5 a.m. after kissing his mother goodbye. He collapsed at work a few hours later.

Swine flu jab takes hit as man, 91, falls ill

The Standard, 15 January 2010
http://www.whale.to/vaccine/swine_flu_jab.html
http://www.thestandard.com.hk/news_detail.asp?pp_cat=11&art_id=93181&sid=26704544&con_type=1 - deleted

Experts have yet to find a link between the human swine flu vaccine and Guillain-Barre syndrome, the health chief says.

York Chow Yat-ngok's remarks yesterday came as doctors tried to find out whether a 91-year-old man who complained of lower limb weakness after receiving the vaccine is suffering from the rare nerve disorder.

A definitive diagnosis has yet to be made, a spokesman for the Department of Health said yesterday.

The patient, who is in stable condition at Princess Margaret Hospital, received a vaccine for seasonal flu on November 26 and another for human swine flu on January 4.

He began complaining of lower limb weakness on Saturday and was admitted to hospital on Tuesday.

"The patient was assessed by a neurologist. Clinical assessment showed that he had [a] decrease in power in both legs," a Centre for Health Protection spokesman said.

A nerve conduction test came out normal and further test results are pending.

Last week, a 58-year-old cardiologist was diagnosed with Guillain-Barre syndrome after also complaining of lower limb weakness.

He had received the human swine flu vaccine on December 24 and is undergoing treatment at Queen Mary Hospital.

However, experts could not say whether the swine flu jab itself had led to his illness.

Centre for Health Protection controller Thomas Tsang Ho- fai said it would be cause for concern if the number of local cases of the syndrome increased significantly from the current monthly average of six to 12.

Meanwhile, 2,604 people were vaccinated in the 24 hours ending at 1pm yesterday. The daily number of people taking the human swine flu shot has been on the decline since the cardiologist was diagnosed with Guillain-Barre syndrome.

As of Wednesday, 34,697 people had been confirmed with swine flu in the city. Fifty-six have died.

THE FLU CASE

The Authorities knew the Risk, says Danish Doctor

The Flu Case, 19 January 2010, 11:54

https://web.archive.org/web/20100220012754/http://www.theflucase.com/index.php?option=com_content&view=article&id=2604%3Athe-authorities-knew-the-risk-says-danish-doctor&catid=1%3Alatest-news&Itemid=64&lang=en
http://whale.to/vaccine/authorities_knew.html

Medical doctor, Jytte Hestbech, Copenhagen is in the unique position of being both an MS patient as well as former vicedirector of Forensic Institute in Denmark.

She estimates, that the authorities in advance knew the risqué of taking the vaccine against the swine flu. It is well known, that the activation of the immune systeme may contribute to a process of disease-development or lead to relapse in the group of autoimmune diseases as for example multiple sclerosis. In spite of this, the MS-patients in Denmark have specificially been recommended to take the vaccine, she says.

Jytte Hestbech presumes, that the authorities at some level or other have knowledge about mercury in vaccines playing a role in the development of autoimmune diseases.

The authorities have chosen to hide for the population, that there is a risk in taking the vaccine. They have also chosen to hide for patients with MS, that they run a risk of aggravation of their disease by taking the vaccine.

According to Dr Jytte Hestbech it is not easy to see through, why the authorities secretly have decided to expose the citizens to such serious dangers.

THE FLU CASE

Ulla Danielsen

38 Cases of Guillian Barré and 11 cases of Multiple Sclerosis following vaccination against H1N1

The Flu Case, 19 January 2010, 11:50
https://web.archive.org/web/20100220012750/http://www.theflucase.com/index.php?option=com_content&view=article&id=2603%3Aemea-registers-38-cases-of-guillian-barre-and-11-cases-of-multiple-scelorosis-from-swine-flu-jab&catid=1%3Alatest-news&Itemid=64&lang=en

The European Medicines Agency (EMEA) has registered 38 cases of Guillian Barré Syndrome, an illness with paralysations, following vaccination against the swine flu (H1N1) since the vaccination campaign started.

Senior medical doctor, Doris Stenver, head of the department for consumer safety at the Danish Pharmaceutical Board (Laegemiddelstyrelsen) 11 cases of multiple sclerosis (MS) have been registered.

EMEA covers the 27 EU countries plus Norway and Iceland.

H1N1 Meeting in Copenhagen
Doris Stenver participated Wednesday in an open meeting about the swine fluat the pharmaceutical faculty at the University of Copenhagen in Denmark.

Since that meeting, the figures communicated by Doris Stenver, have had to be revised and are higher than what was presented at the meeting Wednesday.

The vaccine Pandemrix accounts for 23 cases of Guillian Barré Syndrome in Europe.

Concerning Focetria the European Medicines Agency (EMA) has registered 13 cases of Guillain Barré Syndrome while Celvapan accounts for two cases.

Furthermore the three types of vaccine each account for one case of Miller-Fischer Syndrome. That is a rare, acquired nerve disease that is considered to be a variant of Guillain-Barré syndrome.

11 Cases of MS following H1N1-vaccination
Altogether EMEA has registered 11 cases of multiple sclerosis (MS) following vaccination against H1N1 in Europe. Of these Pandemrix is responsible for nine cases and Focetria for two cases.

Meanwhile, according to senior medical doctor, Doris Stenver, the prevalence of Guillian Barré and multiple sclerosis among citizens vaccinated against H1N1 is not causing concern, when compared with the prevalence of these diseases in the background population.

"When you compare with background data for Europe as a whole, there is no reason for panic," says Doris Stenver.

In Denmark a single case of suspected Guillain Barré has been registered following vaccination. Some cases of sensory disturbances and paralysations have also been registered but nothing like MS says, Doris Stenver.

As of January 11, 2010 32.4 million people in Europe had been vaccinated against the swine flu.

ABC NEWS

School Staff get Insulin instead of Swine Flu Shot

ABC News, Wellesley, Mass.19 January 2010
https://web.archive.org/web/20100126215744/https://abcnews.go.com/GMA/WaterCooler/wireStory?id=9605600

Mass. elementary school staff members mistakenly given insulin instead of swine flu vaccine.

Wellesley school officials said several staff members at an elementary school had to be taken to the hospital after being injected with insulin rather than the swine flu vaccine. Superintendent Bella Wong said no students were ever in danger at Friday's vaccine clinic for staff at Schofield Elementary School and all the people who got the wrong shot have recovered.

Wong, in a letter to staff and parents Monday, said the insulin belonged to students with diabetes and was provided by their parents.

Wong said in the letter that the school nurse who administered the insulin to staff has been placed on paid administrative leave pending an investigation. She did not give the nurse's name.

ABC NEWS

How Did School Staffers Get Insulin Instead of Flu Vaccine? Officials looking for answers in vaccination mix-up

ABC News, 20 January 2010, 7:24 AM
https://abcnews.go.com/Health/SwineFluNews/school-staffers-insulin-swine-flu-shot/story?id=9606504

Jan. 20, 2010; - When staff members at a Wellesley, Mass., school went to the nurse last Friday, they expected to be injected with a vaccine for the H1N1 flu. What they received instead was a shot of insulin resulting in about with low blood sugar.

While the staffers seem to be suffering no long-term damage from mistakenly receiving the insulin injections, investigations are ongoing to determine what caused the medical error. Indications thus far have been that a school nurse was responsible. The nurse has been temporarily relieved of duty.

While ABC News contacted people at the departments of health for the town of Wellesley and the Commonwealth of Massachusetts, as well as the Wellesley School District, it remains unclear how the flu vaccine, which can be distributed in pre-filled syringes or vials, was mistaken for insulin, which is drawn from a vial because each dose needs to be calibrated when it is given.

Such errors have happened before. This past fall, a number of people in the neighboring town of Needham received a seasonal flu vaccine in place of the H1N1 vaccines they were supposed to receive. And in 2007, a teacher in the nearby town of Attleboro also received an injection of insulin instead of the intended flu shot.

"Mistakes can always be made," said Lisa Lowery, a registered nurse and immunizations program manager for the Visiting Nurse Service in Indianapolis. While she is reluctant to blame the nurse, she said other steps can be taken to avoid such a problem.

The benefit of having a nurse specifically performing a vaccination clinic, according to Lowery, is that it allows the nurse to be more focused. "You're in a habit of doing what you're doing. You're doing one vaccine and only one vaccine," she said.

"In practices, you're taught to take the bottle to another nurse and have her double-check what you're about to give," she said – a situation that isn't possible when a school nurse alone is administering vaccine.

"That nurse is not used to injecting vaccines as a school nurse," said Lowery. "It would have been her habit to pick up insulin. Having someone to back them up and check them out would have prevented some more errors. If you're holding a vaccination clinic, use someone who's used to doing that."

Kay Renny, a registered nurse and manager of community programs for the Visiting Nurse Association of Southeast Michigan in Detroit said other steps are typically taken to avoid such a problem.

She said when her nurses are giving out both seasonal and swine flu vaccines, they do so in two separate lines with two separate forms, which do not look alike, so that nurses – who are only administering one shot – will notice. "This is the first year where we're administering two flu vaccines at the same time," she said, explaining it presented a new challenge.

When a mistake happens, "It doesn't hurt them, but it doesn't help them. What they want is what they're there for," said Renny. "You try to put steps in place to avoid that happening."

She noted that the vials for insulin and flu vaccine are similar but the syringes are different, with those for insulin being smaller. "Whenever administering any kind of medication, you have to double check when you have multiple kinds of medication in front of you. You really need to double check your double check."

10 hospitalized after insulin administered instead of flu shots

CNN, 8 November **2019**, 9:49 AM EST,
https://edition.cnn.com/2019/11/07/us/oklahoma-flu-shot-mix-up/index.html

(CNN) Ten people at a care facility in Oklahoma were hospitalized after they were injected with insulin instead of a flu shot, police said.

Eight of the patients were residents of Jacquelyn House and two were employees, Sgt. Jim Warring, with Bartlesville Police Department told CNN. The facility serves intellectually and developmentally disabled people, according to the website of AbilityWorks, the company that owns the eight-resident site.

EMS and fire crews responding Wednesday afternoon "found … multiple unresponsive people," police Chief Tracy Roles said during a news conference covered by CNN affiliate KTUL.

Most patients' suffering symptoms after the medication was administered "were not able to explain the issues," Warring said. "Many of them are not vocal and not able to walk."

"All these people are symptomatic, lying on the ground, needing help, but can't communicate what they need," Roles said. "That's why I give a lot of praise to the fire and EMS staff for doing an outstanding job of identifying the problem."

The pharmacist who injected the insulin was a contractor and went to the facility on Wednesday to administer the flu shot to residents and employees, Rebecca Ingram, CEO of AbilityWorks of Oklahoma, said in a statement.

Ingram said all people who received the injection had reactions and were taken to Jane Phillips Hospital in Bartlesville.

Several remained hospitalized Thursday due to the long-acting insulin that was administered, police said.

Ingram didn't discuss whether the residents and employees were injected insulin but said authorities were investigating the "cause of the reactions to the injections."

"I've never seen where there's been some sort of medical misadventure to this magnitude," Roles said. "But again, it could have been a lot worse. Not to downplay where we are, but thinking about where we could be, it could certainly have been very, very tragic."

Tony D. Sellars, director of communications for the Oklahoma State Department of Health, said his agency will review the facility's report on the incident "to determine if we need to follow up or if their action was sufficient."

"There is no reason to suggest at this point that the facility should have had a reasonable suspicion that this sort of error would occur or be preventable on their part," Sellars said.

An investigation was still underway on Thursday.

One small needle, a world of trouble

Toronto Sun, 30 January 2010, 9:09 pm
https://web.archive.org/web/20100201225400/http://www.torontosun.com/news/columnists/michele_mandel/2010/01/30/12680636.html

Downstairs in the rehab wing of Markham Stouffville hospital, in a private room with a sunny window, lies Donna Hartlen, a young mother who is now partially paralyzed.

The Whitby woman can't stand without leaning on a walker and her legs are too numb to allow her to walk for more than a few steps. The right side of her face is paralyzed, she can't properly chew solid food and her right eye is bandaged because she can no longer blink to protect it.

Until five weeks ago, she was a perfectly healthy woman spending Christmas with her family in Nova Scotia. And then on Dec. 29 she was rushed to an emergency room in Halifax, suddenly unable to stand on feet.

The doctors diagnosed her with Guillain-Barre syndrome, a rare neurological condition characterized by sudden weakness or paralysis. And while no one seems willing to discuss the likely cause, the 39-year-old knows exactly where the fault lies.

She blames the H1N1 flu shot she received on Dec. 13 – two weeks before her symptoms suddenly appeared.

Of course, there is no way to know for certain. But Hartlen has only grown more convinced since chatting by chance in the hall with the older gentleman from the hospital room next door.

Don Gibson has GBS as well, with legs so numb now that he is confined to a wheelchair. It turns out that not only was he also vaccinated against H1N1, but he got the shot just two days before Hartlen, in the very same Markham doctors' office.

"It's way too coincidental," insists the slight mom, her words slurred because the right side of her face will not move. "It's either a bad batch or a lot more people are getting this than they are talking about."

Her 80-year-old neighbour is equally convinced that the H1N1 vaccine to blame. "It must have been a bad batch," Gibson believes. "But nobody is saying anything. I know I signed a piece of paper and there's no liability but it's pretty scary."

They are now comrades in arms, an unlikely duo who share a rare illness and a similar vaccination history that no one wants to acknowledge.

According to the Public Health Agency, there are about 600-700 new GBS cases a year in Canada, caused usually by food-borne bacteria, respiratory infections or surgery.

"The risk of getting GBS after any flu vaccine is about one case for every million doses distributed," the website says. "The benefit of the vaccine outweighs this theoretical risk."

So far, the agency says they haven't had any unusual spike in GBS – there's been 22 cases following the H1N1 vaccination – or .87 per million doses distributed. But Hartlen questions how many GBS patients are actually being reported; she says she was the one who finally called her local public health department because no medical professional seemed interested in the possible connection.

"Not a single doctor we've talked with will even remotely discuss that it's the H1N1 shot," marvels Hartlen. "They almost pretend they don't hear you. They don't want to alarm the public and they don't want you to stir up trouble."

So GBS patients like Hartlen and Gibson are on their own.

Right now, Quebec is the only province with a no-fault vaccine injury compensation program in place.

"It's a horror story of how little Ontario will do to help patients that come down with this after the government promotes it so much," complains her husband, Wayne Burke.

They have two little girls at home, just 4 and 2. He works full-time at Telus; she was a self-employed business systems analyst. With no family in Whitby, they flew in her parents from Nova Scotia, but the elderly couple can't look after the kids indefinitely.

Meanwhile, Hartlen has been told it can take months – and up to a year – before she completely regains all movement. So how is the partially-paralyzed mom supposed to take care of two young children until then?

"If my kids were 10 and 12 it would be different. But a four and two-year-old need 100% attention and I can't give it to them," she worries.

So she's hardly unreasonable in expecting some kind of government support. But after countless phone conversations with every level of bureaucrat, she's learned there will be no such thing.

"They're the ones who push this vaccine. They promote it every five minutes on TV. So I do what they say and I get GBS and they're not going to help me?

"I need help for my kids - I'm not looking for anything extravagant. I'm not an ambulance chaser. I don't want to sue anybody. I just want to get my kids looked after while their father is at work."

Instead, there is only a shameful silence.

Donna Hartlen, a young mother who is now partially paralyzed, has been diagnosed with Guillain-Barre syndrome.
Hartlen, seen in her hospital room with her husband Wayne Burke, blames the H1N1 flu shot. (Stan Behal, Toronto Sun)

THE FLU CASE

Katherine Smith

Open letter on possibly carcinogenic Baxter swine flu jab
Could Baxter's A/H1N1 influenza vaccine ("Celvapan") endanger your health?

The Flu Case, 2 February 2010
https://web.archive.org/web/20100220013339/http://www.theflucase.com/index.php?option=com_content&view=article&id=2680%3Aopen-letter-on-possibly-carcinogenic-baxter-swine-flu-jab&catid=41%3Ahighlighted-news&Itemid=105&lang=en

Dear Health Professional,

Please read this letter carefully, regardless of whether or not you support vaccination.

In 2009, the NZ Ministry of Health *decided to purchase 300,000 doses* of an A/H1N1 influenza vaccine manufactured by Baxter International for targeted distribution to health professionals, police, firefighters and other emergency personnel in the event that the A/H1N1 influenza pandemic warranted its use.
=>https://web.archive.org/web/20180413122315/http://www.radionz.co.nz/news/world/7846/distribution-talks-underway-for-swine-flu-vaccine
=> http://www.moh.govt.nz/moh.nsf/indexmh/influenza-a-h1n1-questions#vaccine (28/10/10 - deleted)

As you probably know, fears that the new A/H1N1 strain would turn out to be devastating have proved to be largely groundless with NZ's influenza death rate being comparable to that of seasonal influenza. [Baker M, et al. Pandemic influenza A(H1N1)v in New Zealand: the experience from April to August 2009]
=> https://web.archive.org/web/20090829164130/http://www.eurosurveillance.org/ViewArticle.aspx?ArticleId=19319

Baxter International's recent *safety record in the production of biological products is very poor.* You may recall the problems with the company's Heparin in 2008 in which at least four people died due to the product's being contaminated, while hundreds more became ill as a result of its use.
See: Baxter Heparin Contaminant Found. – Medical News Today, 6 Mar 2008;
https://web.archive.org/web/20080309032059/http://www.medicalnewstoday.com/articles/99662.php

An investigation into this debacle found that Baxter was sourcing *raw materials from an uncertified Chinese factory* that had never been inspected by the Chinese drug regulators.
See: Heparin Chinese supplier was never checked by Chinese Drug Regulators. – Medical News Today, 6 Feb 2008
https://web.archive.org/web/20080218072441/http://www.medicalnewstoday.com/articles/97598.php

In February 2009, Baxter distributed to sixteen labs in four different countries a bulk seasonal (H3N2) influenza vaccine product that was *contaminated with live bird flu (H5N1) viruses*. This could potentially have sparked a deadly H5N1 influenza pandemic, but fortunately staff in a Czech laboratory discovered the problem in time.
See: Branswell H. Baxter: Product contained live bird flu virus. – Toronto Sun, 27 February 2009;
https://web.archive.org/web/20090302095805/http://www.torontosun.com/news/canada/2009/02/27/8560781.html

The Czech Republic subsequently refused to enter into a contract with Baxter for A/H1N1 influenza vaccine as Baxter *refused to guarantee the vaccine's safety* nor take responsibility for compensating recipients who might suffer side effects from the vaccine's use.
See: Baxter not to provide anti-swine flu vaccine to Czechs. – Ceske Noviny, 3 August 2009;
https://web.archive.org/web/20090822003914/http://www.ceskenoviny.cz/tema/zpravy/baxter-not-to-provide-anti-swine-flu-vaccine-to-czechs/391210

Despite having been informed of Baxter International's recent history of producing *contaminated biological products*, the New Zealand Ministry of Health maintained its supply contract with Baxter. This decision is currently the subject of a complaint to the Solicitor General – as is the decision to

continue a vaccine supply agreement with CSL despite an FDA inspection of its Australian vaccine production factory which *found numerous safety code violations.*

deleted => http://www.entrepreneur.com/tradejournals/article/202644880.html

Baxter's A/H1N1 influenza vaccine ("Celvapan") is produced in "Vero cells" which are derived from green monkey kidney tissue. => http://en.wikipedia.org/wiki/Vero_cell

Cell lines of this type have the potential to be *contaminated with viruses such as Simian Virus* 40 (SV40) a monkey virus of known oncogenic (tumour producing) potential. (For information about SV40 and cancer in humans please see => Horwin M. Simian Virus 40 (SV40): A Cancer Causing Monkey Virus from FDA-Approved Vaccines. Law J Sci & Tech, 2003, 13(3), http://www.sv40foundation.org/Alexander.html

The Minister of Health responded to a request made under the Official Information Act (OIA) by stating that the Vero cell line used by Baxter has been tested and found to be free from SV40. However, he refused to release the documents necessary to prove this assertion. (This refusal is currently the subject of a complaint to the Ombudsman.)

Moreover, the Vero cell line used to culture the A/H1N1 influenza viruses for Baxter's "Celvapan" vaccine, is a *neoplastic cell line*. The FDA is currently investigating whether residual DNA from neoplastic cells (like Vero cells) used in vaccine manufacture can cause cancer in vaccine recipients.

Lewis A. Development of Assays of Defined Sensitivity for the Regulatory Management of Novel Cell Substrates http://www.fda.gov/BiologicsBloodVaccines/ScienceResearch/BiologicsResearchAreas/ucm127304.htm

The NZ Minister of Health *is aware of this risk*. However, he has no plans to cooperate "at this time" with the US FDA on research on this issue. According to the Minister, the Vero cells line used by Baxter in the production of "Celvapan" is one that minimises the possible cancer risk from the vaccine. However, he refused to release any of the documents to prove this assertion.

Moreover, he stated that the NZ Ministry of Health *would not conduct independent testing* of Baxter's A/H1N1 influenza vaccine prior to its use in New Zealand. Such testing could provide vaccine recipients with assurance that the vaccine is not contaminated with H5N1, SV40, any other adventitious microorganisms, oncogenic DNA fragments or any other inadvertent contaminants that could pose a health risk. In other words, The Ministry of Health is relying solely on information supplied by Baxter – which has a massive financial interest in its products – attesting to the safety and efficacy of "Celvapan". Given the recent history of the company, I don't find this reassuring, do you?

The datasheet for "Celvapan" is now available on Medsafe's website. *CELVAPAN: Pandemic influenza vaccine* (whole virion, Vero cell derived, inactivated) suspension for injection; Qualitative and quantitative composition https://web.archive.org/web/20100526012255/http://www.medsafe.govt.nz/profs/Datasheet/c/Celvapaninj.pdf

It is worth reading to get an idea of the possible side effect profile of Baxter's influenza vaccine. (Please note that it appears that there are as yet no Phase III trials Baxter's A/H1N1 influenza vaccine; thus much of the data on the datasheet comes from trials of Baxter's H5N1 vaccine. Moreover, the Phase III trials of Baxter's H5N1 vaccine have yet to be completed.)

deleted: http://clinicaltrials.gov/ct2/show/NCT00711295?term=H5N1+influenza+vaccine+%2B+Baxter&rank=2 => https://clinicaltrials.gov/study/NCT00711295

Using data from an H5N1 influenza vaccine to justify the use of an H1N1 influenza vaccine was considered acceptable for the registration process, due to the "pandemic". Potential side effects of concern for Celvapan include sudden *hearing loss, paresthesia, arthralgia* (from H5N1 influenza vaccine trials) while post marketing surveillance of H1N1 influenza vaccine recipients include *convulsions, anaphylaxis and influenza-like illness*, among others.

It is also important if you are pregnant (or treat pregnant patients) to realise that according to Baxter's datasheet there have been clinical trials on the use of its A/H1N1 influenza vaccine "Celvapan" during pregnancy (or while breastfeeding). This is of concern because pregnant women vaccinated with A/H1N1 influenza vaccines in North America have reported *foetal death* and *miscarriages*.

Reports of H1N1 Vaccine Causing Miscarriages. – Prevent Disease, 7 November 2009; https://web.archive.org/web/20091112143056/http://preventdisease.com/news/09/110709_H1N1_vaccine_miscarriage_reports.shtml

9 New stories of Pain and Loss from Pregnant Women who lost their Babies after receiving the H1N1 Vaccine. – The Flu Case, 18 January 2010.
https://web.archive.org/web/20100413024019/http://www.theflucase.com/index.php?option=com_content&view=article&id=2593%3Ais-the-h1n1-swine-flu-vaccine-causing-miscarriages&catid=1%3Alatest-news&Itemid=64&lang=en

Another factor to take into account when considering whether or not to be vaccinated with "Celvapan" is that influenza vaccines have a long history of producing disappointing results in terms of preventing influenza or influenza like illness. A recent article published in the British Journal of Medicine stated that:

"In children under 2 years inactivated vaccines had the same field efficacy as placebo,8 and in healthy people under 65 vaccination did not affect hospital stay, time off work, or death from influenza and its complications." => Demicheli V et al. Vaccines for preventing influenza in healthy adults. Cochrane Database Syst Rev 2004; (3); CD001269; https://pubmed.ncbi.nlm.nih.gov/15266445/

The author also expressed surpise at the lack of safety studies:

"A Cochrane Database Systematic Review found only one old trial with data from 35 participants aged 12-28 months.8 In the general population of elderly people, despite a dataset of several million observations, safety was only reported in five randomised controlled trials (2963 observations in total) on local and systemic adverse events seen within a week of giving parenteral inactivated vaccine."

Rivetti D et al. Vaccines for preventing influenza in the elderly. Cochrane Database Syst Rev 2006;(3):CD004876.

He recommended that in light of the evidence poor effectiveness of inactivated influenza vaccine, poor methodology of some studies and the surprisingly small amount of information relating to vaccine safety, that a "a re-evaluation [of influenza vaccination programmes] should be urgently undertaken."

Jefferson T. Influenza vaccination: policy versus evidence. BMJ. 2006 Oct 28;333(7574):912-5. doi: 10.1136/bmj.38995.531701.80. http://www.bmj.com/cgi/content/full/333/7574/912

I hope that this letter gives you some starting points for investigating the A/H1N1 influenza vaccine programme for yourself – or at least gives you some information to help you make a more informed decision about its use.

As someone who is grateful for the excellent care I have received in the NZ public health system (most recently following an accident in which I suffered three fractures) I have the utmost respect for the good work done by health professionals. My aim in writing this letter is to bring your attention to an issue that could be of vital importance to your own health.

Yours sincerely,
Katherine Smith

Flu shot blamed for paralysis
Kingston woman on mend, hoping to walk again

Toronto Sun, 6 February 2010, 8:07
https://web.archive.org/web/20100210015930/http://www.torontosun.com/news/columnists/michele_mandel/2010/02/06/12774076.html

(TORONTO SUN) Just before Christmas, Stephanie Willette went from being a healthy nursing student to suddenly being a helpless patient paralyzed from the neck down with a tracheotomy so she could breathe.

Today the 20-year-old is slowly recovering in a Kingston rehab hospital, still unable to sit up, but hoping that she'll eventually walk again.

The Lindsay woman is yet another person stricken with Guillain Barre Syndrome, yet another whose family blames her H1N1 flu shot for triggering the rare neurological condition.

"They can't prove it, but they can't disprove it. She was perfectly fine until two weeks after her shot," says her angry mom Karen. "I think there's a lot more cases out there than the government's letting on. It's a big secret."

According to the ministry of health, they are investigating just four reported cases of GBS in Ontario following the province's mass inoculation of five million people.

But we've already told the harrowing stories of two patients who blame their debilitating onset of GBS on the swine flu shot – which they received within days of each other at the same Markham doctors' clinic.

Since then, four more GBS victims have come forward to the Sunday Sun. With the addition of a Hamilton case reported last November, that's seven Ontario cases by our count alone.

So exactly how many have really been devastated by this highly touted vaccine? And why is Quebec the only province that has a no-fault compensation program for the unlucky few who suffer such a crippling side effect?

GBS can cause mild muscle weakness or severe paralysis and is diagnosed in about 600 Canadians every year after a bout with food-borne bacteria, viral infection or surgery.

Far more rarely, it can develop up to six weeks after a flu shot. It's there in the waiver's fine print: The risk of getting GBS after any flu vaccine is about one for every million doses.

While increased cases of GBS were found after the 1976 swine flu vaccine, there's been no similar upsurge reported with this season's shot. But how many cases are not being properly reported?

As of Jan. 23, the Public Health Agency of Canada was tracking 24 cases following vaccination, or .95 per million as expected. "Concerns about GBS have not emerged in connection with H1N1 vaccines," the agency says.

That's hardly comforting to another mother who almost lost her son last month. "These numbers mean absolutely nothing when your child is lying in intensive care fighting for his life," says Cathy, whose son asked that their last name not be used.

"These numbers mean absolutely nothing when your child is lying in intensive care fighting for his life," says Cathy, whose son asked that their last name not be used. "Then the odds are more like one in one."

Her son Michael was a strapping, fit 26-year-old hospital worker who began complaining of tingling in his feet four weeks after his H1N1 shot. On Dec. 5, as he was losing feeling in his legs, his mom rushed him to St. Joseph's hospital. A spinal tap confirmed GBS.

And then he deteriorated so quickly that he spent four days in intensive care, completely paralyzed.

"It was brutal," Michael recalls, back at his Etobicoke home. "You're trapped inside your brain. I couldn't move. I couldn't even swallow my own spit. It was hell and there was a time I just wanted to die."

He's one of the lucky ones. His recovery has been almost as stunningly quick as his descent into paralysis. After a month in hospital and two weeks at West Park rehab, he's weak, but walking again. "It feels like a bad dream," he says.

But not for his mother. She wrote a scathing letter to several health officials, including Dr. David Butler-Jones, Canada's chief medical officer of health who has spent months urging everyone to get their H1N1 shot.

"I look forward to your replies as to how you can compensate Michael for his pain and suffering since all health officials promise over and over again that the H1N1 vaccine is safe," she wrote. "What will you do for unlucky people such as Michael?"

A month later, and no one has even had the decency to reply.

CBC

H1N1 shot blamed for Calgary woman's rare disorder

CBC News, 23 February 2010, 1:53
https://www.cbc.ca/news/canada/calgary/h1n1-shot-blamed-for-calgary-woman-s-rare-disorder-1.954684

A Calgary woman regrets getting the H1N1 shot after her doctor told her it likely caused a rare and painful disorder.

Norma Goldring said she felt compelled to get an H1N1 vaccine because she is diabetic and has had a heart attack, two factors that Alberta Health noted as putting people at higher risk for serious complications from swine flu.

But soon after getting the shot last winter, Goldring felt ill. "My body was aching and I was throwing up. Then I developed a spot on my leg," she said.

The rash spread quickly and Goldring ended up in hospital on Christmas Day. "By the time I got to emergency, it spread pretty bad and turned to blisters."

Her kidneys were shutting down. Doctors eventually diagnosed it as vasculitis, an inflammation that destroys blood vessels.

Her doctor, who asked not to be named, concluded it was probably connected to the H1N1 shot. Goldring, according to her doctor, is one of only 31 people since 1974 to have had this type of reaction to a flu shot.

Won't get shot again, says Goldring

Now, even using a walker to get from her living room to her kitchen causes her excruciating pain. She is on pain killers and steroids.

"It was like I was put through a fire. It was like someone lit me on fire," she said.

Goldring said she won't get a flu shot again. Desmond Fordyce, her partner, said he is worried the vaccine wasn't tested properly before widespread public vaccinations began.

"I think they're killing you more than giving you something for making you better," he said.

Dr. Glen Armstrong, head of the microbiology and infectious diseases department at the University of Calgary, said the H1N1 vaccine is safe. "It's very clear that the benefits of having people get vaccinated, far, far outweigh the risks of the very small number of adverse reactions to the vaccine."

So far, 25 million doses of the vaccine have been distributed across Canada. Nearly 6,000 H1N1 shots resulted in an adverse reaction, of which more than 200 were considered serious. Health officials are investigating 13 post-shot deaths. (Note: "distributed" does not mean "administered". The numbers do NOT match the information we were given indicating only about a third of Canada's population actually took the shot, which would mean the 25 million doses is a misleading figure. And we are also pretty sure that the 6000 events they are talking about do NOT include a lot of people whose conditions post-shot were NOT linked to the shot. Boldfacing and comment are mined)

Alberta health officials told CBC News they have talked to Goldring's doctor and will continue to investigate what happened in her case.

The province has seen 1,276 people hospitalized with H1N1 since April 2009 and 71 deaths have been connected to the virus.

THE FLU CASE

Carl O'brien

Irish Times finally looks at reported adverse reactions to swine flu jab, believed to be just tip of iceberg

The Flu Case, 2 March 2010, 10:28

https://web.archive.org/web/20100508003237/http://www.theflucase.com/index.php?option=com_content&view=article&id=2882%3Airish-times-finally-looks-at-reported-adverse-reactions-to-swine-flu-jab-believed-to-be-just-tip-of-iceberg&catid=1%3Alatest-news&Itemid=64&lang=en

Almost 1,000 reported cases included vomiting or diarrhoea, fever, swollen glands and injection-site swelling

The Swine flu vaccine caused almost 1,000 suspected adverse reactions last year, more than any other vaccine or medicine over the past five years.

However, health authorities insist the vaccine is safe and that the balance of risk and benefits for the vaccine remains positive.

The Irish Medicines Board (IMB) says the most frequently reported reactions for the vaccine have been relatively mild injection-site reactions (such as swelling), gastrointestinal problems (such as vomiting or diarrhoea) and flu-like symptoms (such as fever and swollen glands).

The Irish Times requested a breakdown of the drugs or vaccines responsible for the highest number of adverse reactions from the IMB under the Freedom of Information Act over the past five years.

The data shows there were about 11,500 adverse reaction reports for drugs or vaccines submitted to health authorities between 2005 and the end of 2009.

The number of adverse reactions does not necessarily represent the risk profile of each drug or vaccine, as figures for the number of people using each drug are not available. Also, it does not provide a breakdown of the number of serious or mild adverse reactions.

The figures show that the anti-psychotic drug Clozapine, also known as Clozaril, ranks second-highest in the number of adverse reactions (883).

Common adverse effects of the drug include dizziness, rapid heartbeat, constipation, excess saliva production and weight gain.

Another drug used to treat psychosis, which has attracted a relatively high number of adverse reactions, is Risperidone (154), which is more commonly known as Risperdal.

The childhood combination vaccines, which includes jabs for whooping cough, measles, mumps and rubella, ranked third highest (722) in the number of adverse reactions.

Again, health authorities insist the vaccine is safe and that most adverse reactions are mild, such as swelling, redness or fever.

Paracetamol (715), one of the most commonly used pain killers, is sometimes associated with minor issues such as hives, rashes or – if taken at high levels over a prolonged period of time – kidney damage.

Lipitor, also known as Atorvastatin, was linked to 225 adverse reactions. Studies show these typically range from joint pain and stomach upset to more serious issues such as severe muscle problems.

A spokesperson for the IMB said adverse reaction reporting rates were influenced by the seriousness of the reactions, their ease of recognition and the extent of use of a particular medicine.

In addition, reporting rates are also influenced by campaigns aimed at healthcare professionals to submit reports on specific drugs or vaccines, often as part of ongoing post-marketing surveillance.

Publicity about a particular medicine or its safety may also lead to increased reporting.

The two swine flu vaccines available in Ireland since November – GlaxoSmithKline's Pandemrix and Baxter's Celvapan – have been subjected to a particular vigilance.

In the first two months of 2010, more than 400 additional adverse reactions had been recorded, meaning that the overall total tops 1,400.

Adverse Reactions

Drugs or vaccines with the most adverse reactions between 2005 and 2009:

1. H1N1 vaccine: 934 (Swine flu vaccine.)
2. Clozapine: 883 (Anti-psychotic drug, also known as Clozaril.)
3. Childhood combination vaccines: 722 (Typically the six-in-one to prevent diseases such as diphtheria, tetanus, etc.)
4. Paracetamol: 715 (Pain killer.)
5. Atorvastatin: 225 (Lowers blood cholesterol, also known as Lipitor.)
6. BCG vaccine: 207 (A vaccine to protect against tuberculosis.)
7. Adalimumab: 170 (A medication for the treatment of rheumatoid arthritis, also known as Humira)
8. Varenicline: 155 (Anti-smoking drug, also known as Champix.)
9. Venlafaxine: 155 (Anti-depressant, also known as Efexor.)
10. Risperidone : 154 (Anti-psychotic medicine, also known as Risperdal.)

FOCUS online

Nach Schweinegrippe-Impfung fordern Erkrankte Entschädigung

Focus, 3 March 2010, 13:01

https://web.archive.org/web/20120830041249/http://www.focus.de/gesundheit/gesundheits-news/schweinegrippe-nach-schweinegrippe-impfung-fordern-erkrankte-entschaedigung_aid_486212.html

Betroffene von Folgeerkrankungen nach der Schweinegrippe-Impfung fordern vom Land Nordrhein-Westfalen Entschädigung. Insgesamt seien vier Anträge eingereicht worden, weitere würden erwartet, sagte ein Sprecher des Düsseldorfer Gesundheitsministeriums. Sollte nachgewiesen werden, dass die Schweinegrippe-Impfung Ursache für die Erkrankungen sei, könnte das Land in Regress genommen werden.

Wegen Folgeerkrankungen nach der Schweinegrippe-Impfung fordern erste Betroffene in Nordrhein-Westfalen Entschädigungszahlungen vom Land. Insgesamt lägen derzeit vier Anträge vor, ein weiterer werde erwartet, erklärte ein Sprecher des Düsseldorfer Gesundheitsministeriums am Mittwoch auf DAPD-Nachfrage und bestätigte damit einen Bericht des „Westfalen-Blatts“. Die Anträge werden derzeit von den Landschaftsverbänden Westfalen-Lippe (LWL) und Rheinland bearbeitet.

Sie entscheiden darüber, ob das Land wegen möglicher Impfschäden tatsächlich in Regress zu nehmen ist. Wenn klar belegbar sei, dass Erkrankungen tatsächlich auf die öffentlich empfohlenen Schweinegrippe-Impfung zurückgingen, müsse das Land zum Beispiel für die Kosten der Krankenbehandlung oder für Rentenansprüche aufkommen, erklärte ein LWL-Sprecher. Dem Landschaftsverband in Münster liegt den Angaben zufolge derzeit der Antrag einer 51-jährigen Frau aus dem Kreis Warendorf vor, die nach der Impfung im Krankenhaus behandelt werden musste. Nähere Details nannte der Sprecher nicht.

Kopfschmerzen und Übelkeit

Beim Landschaftsverband Rheinland sind laut „Westfalen-Blatt“ die Anträge eines 30 Jahre alten Mannes aus Düsseldorf, eines 60-jährigen Mannes aus Kleve und eines 71-jährigen aus Fürstenau (Kreis Höxter) eingegangen. Die Betroffenen aus Düsseldorf und Kleve sollen an einer Hauterkrankung leiden. Bei dem 71-Jährigen sollen sich nach der Impfung die Nerven im Schädelbereich entzündet haben und die Augenmuskeln geschwächt worden sein. Zudem plagen den Mann dem Bericht zufolge Kopfschmerzen und Übelkeit. Der Landschaftsverband Rheinland war für eine Stellungnahme zunächst nicht zu erreichen.

Insgesamt wurden nach Angaben des Paul-Ehrlich-Instituts bis zum 30. Dezember bei rund 1.380 Menschen Verdachtsfälle von unerwünschten Reaktionen nach der Impfung gegen die Schweinegrippe gemeldet. Am häufigsten sei über Fieber, Schmerzen der Impfstelle, Kopfschmerz, Schüttelfrost, Übelkeit, Ermüdung, Schwindelgefühl sowie Kreislaufkollaps berichtet worden.

Eine Million Menschen in NRW geimpft

In Nordrhein-Westfalen haben sich laut Gesundheitsministerium bislang rund eine Million Menschen impfen lassen. Da das Land verpflichtet sei, vom Hersteller Glaxo-Smith-Kline 7,4 Millionen Impfdosen des Serums Pandemrix abzunehmen, versuche NRW 6,4 Millionen überzähliger Dosen an andere Staaten zu verkaufen, sagte ein Sprecher des Gesundheitsministeriums dem „Westfalen-Blatt“.

Die Zahl der überzähligen Impfdosen in allen Bundesländern wird von den Gesundheitsbehörden dem Bericht zufolge auf 27,6 Millionen geschätzt. Die Impfquote ist demnach mit 3,5 Prozent in Baden-Württemberg am niedrigsten und mit jeweils zehn Prozent in Sachsen und Sachsen-Anhalt am höchsten.

THE FLU CASE

First claims for compensation for swine flu jab injuries are filed in Germany

The Flu Case, 3 March 2010 13:25
https://web.archive.org/web/20100504185039/http://www.theflucase.com/index.php?option=com_content&view=article&id=2891%3Afirst-claims-for-compensation-for-swine-flu-jab-injuries-are-filed-in-germany&catid=41%3Ahighlighted-news&Itemid=105&lang=en

Four people in the German state of Nordrhein Westfalen (NRW) have filed financial compensation claims for injury they have suffered as a result of taking the Pandemrix swine flu jab, the state's health ministry reported Wednesday, according to „Focus".

A fifth person is expected to file for compensation soon.

A spokesperson confirmed the state government carries liabilty for injury caused by the swine flu vaccine, which was recommended by them. In addition, the federal government in Berlin issued a special recommendation.

Adverse reactions reported by injured patients include respiratory problems, nausea, vomiting, among others.

About one million people in the state of NRW and about 7.5 million people in Germany altogether took the swine flu vaccin.

The compensation claims could be the first of a flood.

They are sure to focus attention on the issue of why GlaxoSmithKline, the manufacturer of Pandemrix, was given blanket immunity from compensation claims when the untested jab was so evidently risky, so leaving the cost of compensating injured patients to tax payers.

Little Women With Big Voices Expose HPV Vaccine Dangers

PR Newswire, 8 March 2010, 09:07 ET
https://www.prnewswire.com/news-releases/little-women-with-big-voices-expose-hpv-vaccine-dangers-86857987.html
https://www.infonews.co.nz/news.cfm?l=1&t=145&id=49116

Denver, March 8, 2010 /PRNewswire via COMTEX/ - Called the "Little Women," six women who have spent the past three years listening, documenting and researching parental concerns about Gardasil have been invited to formally present their information to the FDA on March 12. FDA participants include the Office of Communication, Outreach and Development/Center of Biologics (CBER), Office of Biostatistics and Epidemiology, and Office of Vaccines Research and Review.

The women making the presentation on behalf of the parents whose daughters have died or have been injured by the HPV vaccines are: Karen Maynor, mother of the late Megan Hild, New Mexico; Rosemary Mathis, whose daughter Lauren was adversely injured, North Carolina; Freda Birrell, political activist and lobbyist, Scotland and the United Kingdom; Leslie Carol Botha, broadcast journalist, Colorado; Cynthia Janak, research analyst, Illinois; and Janny Stokvis, research analyst, Netherlands.

Over 17,500 adverse reactions and 61 deaths have been reported to VAERS (estimated 1 to 10% of the population reporting). The National Vaccine Information Center (NVIC) has posted 272 VAERS reports of abnormal pap tests post-vaccination. Reports of deaths and injuries are now coming in from the United States, New Zealand, Australia, United Kingdom, France, Germany, Spain and India.

Birrell has compiled 40 pages of reports of deaths and injuries from the above countries for the FDA. Stokvis and Mathis have compiled data of vaccine injuries and deaths from VAERS. Botha is presenting studies on menstrual cycle evaluation to prevent vaccine injury - and the impact of aluminum on the endocrine system. Janak has researched vaccine ingredients and believes that she has found the reason as to why "healthy" girls have been injured or have died suddenly and unexpectedly within days weeks, months or potentially years after vaccination.

The group has prepared a power point presentation for the FDA "listening session." Each participant will receive a file with over 236 pages of research, data and parental concerns. As soon as the Webinar is over, the group will be releasing their data and research to the public and to the media.

The group was dubbed "Little Women" by the FDA who is impressed with the women's research and how quickly they mobilized a global movement of parents concerned about the safety and efficacy of the HPV vaccines.

FDA invites six women to present evidence of HPV vaccine damage

The Flu Case, 9 March 2010, 14:27
https://web.archive.org/web/20100325183558/http://www.theflucase.com/index.php?option=com_content&view=article&id=2957%3Afda-invites-six-women-to-present-evidence-of-hpv-vaccine-damage&catid=1%3Alatest-news&Itemid=64&lang=en

Seasonal flu shot may increase A/H1N1 risk: studies

Xinhuanet English News, 7 April 2010, 10:55:20.
https://web.archive.org/web/20100409112903/http://news.xinhuanet.com/english2010/health/2010-04/07/c_13240453.htm

BEIJING, April 7 (Xinhuanet) – Regular seasonal flu vaccine may have increased the risk of A/H1N1 flu infection, suggested an article published in Public Library of Science Medicine Tuesday.

The article said four studies, by the Canadian researchers, were carried out in some 2,700 people after an outbreak in April 2009 first signaled a possible connection between seasonal flu vaccine and pandemic flu illness.

Results show that the likelihood of needing medical attention for pandemic flu was 1.4 to 2.5 times greater among people who were vaccinated the previous fall.

In one study, an ongoing sentinel monitoring system was used to assess the frequency of prior vaccination with the seasonal flu vaccine in people diagnosed with A/H1N1 flu in 2009 compared to people without the pandemic flu.

Findings show that seasonal flu vaccination was linked to 68 percent increased risk of getting A/H1N1 flu.

The other studies, including additional case-control investigations and transmission study, reveal that seasonal flu vaccination was associated with a 1.4- to 5.0-times greater risk of having A/H1N1 flu.

However, the authors warn that since all four studies were observational, even careful design cannot rule out the possibility that some undetected methodologic bias affected the results.

Principal investigator Danuta Skowronski, of the British Columbia Center for Disease Control in Vancouver, pointed out that the studies don't show whether there was a true cause-and-effect relationship between seasonal flu vaccination and subsequent swine flu illness, or whether the association was possibly due to a common factor among the people in the studies.

H1N1 Spread Linked to Seasonal Flu Shots - four new studies show

Science Blogs, 8 April 2010, 20:47
https://scienceblogs.com/insolence/2010/04/06/someone-didnt-nail-the-coffin-shut-andre
https://web.archive.org/web/20100613224823/http://www.theflucase.com/index.php?option=com_content&view=article&id=3244%3Ah1n1-spread-linked-to-seasonal-flu-shots-four-new-studies-show&catid=1%3Alatest-news&Itemid=64&lang=en

The four new studies conducted by Canadian researchers conclude that the traditional seasonal flu vaccine seems to have boosted the risk of infection with pandemic H1N1 swine flu by almost double.

In one study, the researchers revealed to use ongoing sentinel monitoring system in order to assess the frequency of prior vaccination with the seasonal flu vaccine in people suffering from H1N1 swine flu in 2009 compared to people without swine flu.

The study discovered that seasonal flu vaccination was linked with a 68 percent boosted risk of falling in prey to swine flu.

"I do think that they did the best they could with the data they had", said Dr. Mark Loeb, an infectious diseases expert at McMaster University in Hamilton who was not part of the study and who seems to be sceptical about the study's conclusion.

The studies, published April 6 in the online journal PLoS Medicine, attributed to the combined of over 40 researchers including many of Canada's top influenza experts. The data is reported to be fetched from four studies that draw cases from British Columbia, Alberta, Ontario and Quebec.

However, the studies *failed to show the presence of a true cause-and-effect link between seasonal flu vaccination and subsequent swine flu illness*, or it is due to presence of a common factor among the people in the study.

=> See above:
D. M. Skowronski, etc. Association between the 2008–09 Seasonal Influenza Vaccine and Pandemic H1N1 Illness during Spring–Summer 2009: Four Observational Studies from Canada. - PLOS Medicine, 6 April 2010 // https://doi.org/10.1371/journal.pmed.10002
https://journals.plos.org/plosmedicine/article?id=10.1371/journal.pmed.1000258

Conclusions: Prior receipt of 2008–09 TIV was associated with increased risk of medically attended pH1N1 illness during the spring–summer 2009 in Canada. The occurrence of bias (selection, information) or confounding cannot be ruled out. Further experimental and epidemiological assessment is warranted. Possible biological mechanisms and immunoepidemiologic implications are considered.

Seasonal flu vaccines increase risk of pandemic H1N1 flu, stunned scientists discover

Natural News, 8 April 2010, 11:42
https://www.naturalnews.com/028538_seasonal_flu_shot_vaccines.html

I remember the H1N1 "swine flu" season of 2009 very well. People were rushing out to get vaccinated, scared half to death by the mainstream media which was pushing false reports that the swine flu would kill tens of millions of people and that only a vaccine could save you. The CDC and health authorities were pushing a double-barreled vaccine strategy that demanded people get both a seasonal flu shot as well as an H1N1 pandemic flu shot. Those who questioned the sensibility of vaccines for fighting the flu were attacked as "baby killers" for not kow-towing to the vaccine mythology that drives Big Pharma's profits to record profits nearly every flu season.

I specifically remember writing an article here on NaturalNews, warning people that taking a seasonal flu shot actually weakened your immune system and made you more susceptible to H1N1 swine flu. => https://web.archive.org/web/20101015053934/http://www.naturalnews.com/027102_vaccines_H1N1_flu_shot.html

This suggestion earned me a highly accusatory email from a CDC employee who suggested that warning people to avoid the swine flu vaccine shot was equivalent to "an act of terrorism" and that all those who questioned vaccines should be arrested and stopped from writing anything on the internet ever again.

(Hilarious, isn't it, how deeply the vaccine mythology drives these vaccine-pushing nut jobs?)

Fast forward six months (or so) and now we have a new scientific paper published in one of the few remaining honest, independent medical journals out there: BLoS Medicine. The title of this study? Check it out:

Does Seasonal Influenza Vaccination Increase the Risk of Illness with the 2009 A/H1N1 Pandemic Virus?

Viboud C, Simonsen L (2010) Does Seasonal Influenza Vaccination Increase the Risk of Illness with the 2009 A/H1N1 Pandemic Virus? PLoS Med 7(4): e1000259. doi:10.1371/journal.pmed.1000259

Care to guess what the study found? In short, it found that people who received the seasonal flu vaccine shot in 2008 were up to 274% more likely to be infected by H1N1 swine flu than those who skipped the season flu shots.

Season flu vaccines have a "counterproductive effect"

This result, which virtually all the top natural health writers openly predicted last year, apparently stunned the researchers. As explained in the published study, "Danuta Skowronski and colleagues report the unexpected results of a series of Canadian epidemiological studies suggesting a counterproductive effect of the vaccine."

In this case, "counterproductive effect" of the vaccine means that it works *against you*. Getting the vaccine shot appears to actually make you MORE susceptible to being infected with (and potentially killed by) a future pandemic.

If this sounds familiar, it's because we've been saying this over and over again to anyone who will listen: Flu vaccines are a medical scam, folks! A Big Pharma hoax. Getting a vaccine shot could actually result in you being killed by the next seasonal flu or pandemic outbreak that comes along. I even wrote this into the lyrics of my hip-hop song *Don't Inject Me*:

=> https://www.naturalnews.com/Dont_Inject_Me_The_Swine_Flu_Vaccine_Song.html

Lyrics:
The swine flu's comin' back
like a viral attack
It's like '76, you gotta cover ya back
But not with a vaccine don't give in to that
Because those medical quacks
are makin money off that, etc...

Criminal neglect at the CDC and WHO?

So it turns out the CDC, WHO and FDA officials who all pushed these vaccines so hard were actually sending people to their graves. Meanwhile, they all engaged in what I consider to be blatant criminal neglect for not mentioning the simple, free solution for preventing virtually any widespread pandemic: Vitamin D and sunlight therapy. Vitamin D, we now know, works *better* than vaccines at preventing a flu infection, and the best part is that it makes your immune system *stronger* for the future, not weaker.

According to the CDC's official figures, well over ten thousand Americans died from swine flu infections. How many of those people could have been saved if they had taken vitamin D supplements instead of a seasonal flu shot? That is the question that now hangs over the heads of all the vaccine pushers at the FDA, WHO and CDC who have yet to admit in a single public story that vitamin D could have saved lives (or that the vaccine might be harmful to anyone).

To hear these agents of Big Pharma say it, vaccines are *always* good for you; they *always* work; and they *never* cause harm. Those are the beliefs of their vaccine cult, and they cannot be swayed by scientific evidence or actual reality.

What the new study actually says

The preamble to the study's findings:

The spring 2009 pandemic wave was the perfect opportunity to address the association between seasonal trivalent inactivated influenza vaccine (TIV) and risk of pandemic illness. In this issue of PLoS Medicine, Danuta Skowronski and colleagues report the unexpected results of a series of Canadian epidemiological studies suggesting a counterproductive effect of the vaccine [4]. The findings are based on Canada's unique near-real-time sentinel system for monitoring influenza vaccine effectiveness.

And here's the real kicker of what they found:

"...receipt of TIV [vaccine] in the previous season (autumn 2008) appeared to increase the risk of pH1N1 illness by 1.03- to 2.74-fold, even after adjustment for comorbidities, age, and geography."

In other words, those who were vaccinated with the previous seasonal flu were 103% to 274% more likely to be infected with H1N1 than those who skipped the vaccine.

And this analysis only measured the effects from one year of seasonal flu vaccines. What might the results show if they tracked consumers' vaccination patterns over the last decade?

I have no doubt that those who rejected vaccines for the greatest number of years would have the lowest rates of H1N1 infections. At the same time, those who received the greatest number of vaccine shots over the last decade would be far more likely to be infected with the H1N1 pandemic flu – perhaps as much as 500% more likely (my guess).

It's all about repeat business

Let me explain the dirty little secret of the vaccine business, because it's exactly the same dirty little secret as the pharmaceutical business: They actually WANT you to get sick so that you keep coming back for more drugs (which make you even sicker).

See, a vaccine actually weakens your immune system from future infections. So the more vaccines you get, the more likely you are to catch the flu in subsequent years. The more you catch the flu, the more you automatically think, "Gee, I must need a flu shot" and you therefore go back to get another shot.

(Ka-Ching $!) Big Pharma scores revenue from you and sends you back out into the world with a weakened immune system yet again, perfectly positioned for endlessly repeating this cycle.

Big Pharma's high-profit medications follow the same strategy: Osteoporosis drugs, for example, actually cause bone fractures. Psychiatric drugs cause psychiatric disorders. Chemotherapy drugs cause cancer, and so on.

What the drug companies have figured out is that a patient cured is a patient lost. But a patient in which *sickness can be induced by the medicine* is a repeat customer! So vaccines, medications and cancer treatments actually become profit centers as they harm hundreds of millions of people who then seek out yet more medical care where they will be prescribed yet more drugs.

The whole medical cycle is absurdly sick, and yet this is the system upon which the entire system of western health care is currently based. The recent health care "reforms," in fact, are nothing more than an expansion of this system to make sure everybody gets sick rather than just those who can afford to buy health insurance.

How to escape the dark agenda of the vaccine pushers

The vaccine pushers have a clear agenda: They want to inject *everyone* -- pregnant mothers, infants, teenage girls and boys, senior citizens and even healthy adults -- with vaccines. In doing so, they can absolutely guarantee a windfall of future business (and profits) from all the people whose immune systems are compromised.

A vaccine is a repeat business generator for the drug companies. It has absolutely nothing to do with your health, or saving the people, or halting any pandemic. It has *everything* to do with trapping the public in a cycle of medical dependence from which they can never escape.

But YOU can escape. It's easy: Just say NO to vaccines and say YES to Vitamin D and sunlight. It's really that simple, and the same goes for your children, too. When you have vitamin D and good nutrition, you don't need vaccines and you're extremely unlikely to catch any seasonal flu.

Don't expect the CDC or WHO to leap right out and admit this, however: These people are still living in the Dark Ages of medicine. They have yet to see the (sun) light. They remain shackled to their distorted, dark beliefs in dangerous chemicals and needles, much like the Orcs were beholden to the Dark Lord Sauron in *The Lord of the Rings*. They are, in a very real way, creatures of deception and darkness who only seek to gain power by depriving the People access to information that could save their lives – information about nutrients, sunlight, antioxidants, anti-viral herbs and many other remedies that make flu vaccines obsolete.

The Dark Lord Sauron, however, is very powerful, as is the CDC, WHO and FDA. They rule with intolerance for opposing views and without any regard for the value of human life. They censor scientific findings and conspire with the enemy drug companies to medicate everyone whether they need it or not. They invoke power through the spread of fear, and they take great solace in their power to dominate innocents. And yet they insist their vaccine cult is the one true belief – their God – and that anyone who dares step forward and question their vaccine mythology is a heretic who should be arrested or destroyed.

We are actually living out *The Lord of the Rings* right now in western medicine and the modern vaccine agenda. The clouds are roiling over the horizon, threatening to shadow us all in censorship

and health ignorance. Meanwhile, we are being stripped of our healthy minds and immune systems through these highly neurotoxic medications and vaccines that make us less and less human with each passing day. It's almost as if the Dark Lord were expanding his own army of dark creatures by destroying the minds of innocents and reshaping them to fit his own medical domination agenda. Coincidentally, it is quite true that those are have already been vaccinated are the most likely to be vaccinated again... perhaps because the vaccine-induced brain damage has kicked in and destroyed their ability to think for themselves.

What the Dark Lords of western medicine fear the most is the truth:
The truth about sunlight. The truth about vitamin D. The truth about nutrition and how natural medicine makes virtually everything in conventional medicine obsolete. The truth, in fact, is what will ultimately destroy this conspiracy of medical darkness that has blanketed our world in darkness for the last century. But there is light at the end of this tunnel, and it's *sunlight!*

Because as long as there are people who are willing to say NO to vaccines and medications, there will always be hope for a revolution in healing that sees the crumbling of the pharmaceutical empire and the rise of a new era of healing freedom.

Teach your children well, friends, because they will need their minds sharp and their bodies fit to rise up against the medical tyranny that now enslaves our fellow brothers and sisters. Teach your children the meaning of freedom and the skills of discernment so that they may tell the difference between tyranny versus freedom. And most of all, teach them the truth about their miraculous innate healing potential so that they will not be cowed into submitting to the tyrants of conventional medicine who prey upon weak minds.

Most importantly, feed your children well so that they will survive the next great pandemic that quietly steals the lives of those who foolishly believed in vaccines. In this way, your healthy children will inherit the earth while those who misplaced their faith by worshipping the Gods of vaccines and pharmaceuticals will quite literally perish.

We live and die by our beliefs, and those who believe in vaccines may very well die by them.

P.S. For the record, I have not been vaccinated for nearly 20 years and I take no pharmaceuticals whatsoever. I travel around the world frequently, and I'm on airplanes and in crowded public places on a regular basis. I can't even remember the last time I lost a single day sick in bed from any flu, pandemic or infection of any kind. I am not afraid of the swine flu and have almost certainly already been exposed to it, although I would never know because I never showed any symptoms. I truly and honestly believe that the next great pandemic, whenever it comes, will demonstrate a devastating mortality rate for those who depend on western medicine's vaccines and pharmaceuticals. Mark my words: The survivors will be those who rejected the vaccines. Will you be one of them?

Vaccinated senior in critical condition

News Gov.HK, 8 April 2010

http://www.whale.to/vaccine/vaccinated.html

http://www.news.gov.hk/en/category/healthandcommunity/html/6c6812e3-49ef-479e-b981-05074b68125b.htm - deleted

A 73-year-old woman who had a human swine flu vaccination is in critical condition after being hospitalised for weakness in her hands and feet, the Centre for Health Protection says.

She developed numbness in her hands and feet on March 4. She was admitted to Kwong Wah Hospital on March 11.

She was inoculated at a public out-patient clinic on December 31. Investigations are underway to ascertain whether she has Guillain Barre Syndrome or other neurological conditions.

Chile's TV reports second case of GSB after swine flu jab

The Flu Case, 16 May 2010, 13:58

https://web.archive.org/web/20100523171412/http://www.theflucase.com/index.php?option=com_content&view=article&id=3507%3Achiles-tv-reports-second-case-of-gsb-after-swine-flu-jab&catid=1%3Alatest-news&Itemid=64&lang=en

Chile's TV news has reported a second case of GBS in Chile following vaccination. This case involved an 80 years old man, in Temuco (southern Chile), who went to a vaccination center in the morning and around 7 pm had neurological problem and is now breathing with the help of a ventilator. Max, a 7 year old child, also developed neurological problems after the swine flu jab.

I am getting more info (through the mail and blog) about more VAERS. All ages, babies and adults with convulsions, palsy, etc. 1 baby is on UTI (Intensive treatment unit)...but this case is not reported yet by media..."

theForeigner Norwegian News in English

Ten people in Norway died as a result of swine flu jab, official numbers just tip of iceberg

The Foreigner // The Flu Case, 18 May 2010, 11:10
http://theforeigner.no/pages/news/swine-flu-vaccine-caused-deaths/ [deleted]
https://web.archive.org/web/20100523172237/http://www.theflucase.com/index.php?option=com_content&view=article&id=3527%3Aten-people-in-norway-died-as-a-result-of-swine-flu-jab-official-numbers-just-tip-of-iceberg&catid=41%3Ahighlighted-news&Itemid=105&lang=en

Ten people in Norway have died as a result of last year's mass vaccination programme against the swine flu (Influenza A H1N1).

According to figures released by the Norwegian Medicines Agency (Statens legemiddelverk), the Pandemrix vaccine also accounted for 801 reported incidents of side-effects. Health authorities considered 201 of these cases to be severe.
=> https://web.archive.org/web/20101003133352/http://theforeigner.no/pages/news/information-about-the-h1n1-flu-vaccine/

Amongst other symptoms, patients experienced severe allergic reactions and cramps. But perhaps the most serious were those who suffered from Guillain-Barré syndrome, causing gradual ascending paralysis up the legs. It can also affect the arms and upper body, and at worst can paralyze the breathing muscles.

The vaccine also affected *pregnant women* and *children*. There were 16 reported cases of abortions, fetal death, or stillbirth. And 58 children were hospitalized for observation due to fainting, fever, fatigue, loss of appetite, and dehydration.
=> https://web.archive.org/web/20101003133437/http:/theforeigner.no/pages/news/pregnant-women-advised-to-take-precautions-against-influenza-a/
=> https://web.archive.org/web/20101003035534/http:/theforeigner.no/pages/news/parents-ignore-swine-flu-vaccination-programme/

Approximately two million people were vaccinated against swine flu last year, and the agency says it's investigating every incident.

Seasonal influenza vaccine and increased risk of pandemic A/H1N1 - related illness: first detection of the association in British Columbia, Canada

Clin Infect Diseases, 1 November 2010; 51(9):1017-27.
doi: 10.1086/656586. PMID: 20887210; PMCID: PMC7107856.
https://pubmed.ncbi.nlm.nih.gov/20887210/

Abstract

Background: In April 2009, an elementary school outbreak of pandemic H1N1 (pH1N1) influenza was reported in a community in northern British Columbia, Canada – an area that includes both non-Aboriginal and Aboriginal residents living on or off a reserve. During the outbreak investigation, we explored the relationship between prior receipt of trivalent inactivated influenza vaccine (TIV) and pH1N1-related illness.

Methods: A telephone survey was conducted from 15 May through 5 June 2009 among households of children attending any school in the affected community. Members of participating households where influenza-like illness (ILI) was described were then invited to submit blood samples for confirmation of pH1N1 infection by hemagglutination inhibition and microneutralization assays. Circulation of pH1N1 was concentrated among households of the elementary school and elsewhere-reserve to which analyses of TIV effect were thus restricted. Odds ratios (ORs) for the TIV effect on ILI were computed through logistic regression, with adjustment for age, comorbidity, household density, and Aboriginal status. The influence of within-household clustering was assessed through generalized-linear-mixed models.

Results: Of 408 participants, 92 (23%) met ILI criteria: 29 (32%) of 92 persons with ILI, compared with 61 (19%) 316 persons without ILI, had received the 2008-2009 formulation of TIV. Fully adjusted ORs for 2008-2009 TIV effect on ILI were 2.45 (95% confidence interval, 1.34-4.48) by logistic regression and 2.68 [95% confidence interval, 1.37-5.25) by generalized-linear-mixed model.

Conclusions: An outbreak investigation in British Columbia during the late spring of 2009 provided the first indication of an unexpected association between receipt of TIV and pH1N1 illness. This led to 5 additional studies through the summer 2009 in Canada, each of which corroborated these initial findings.

Brain-Damaged UK Victims of Swine Flu Vaccine to Get £60 Million Compensation

IBT, 2 March 2014, 2:40 PM GMT
https://www.ibtimes.co.uk/brain-damaged-uk-victims-swine-flu-vaccine-get-60-million-compensation-1438572

Patients who suffered brain damage as a result of taking a swine flu vaccine are to receive multi-million-pound payouts from the UK government.

The government is expected to receive a bill of approximately £60 million, with each of the 60 victims expected to receive about £1 million each.

Peter Todd, a lawyer who represented many of the claimants, told the Sunday Times: "There has never been a case like this before. The victims of this vaccine have an incurable and lifelong condition and will require extensive medication."

Following the swine flu outbreak of 2009, about 60 million people, most of them children, received the vaccine.

It was subsequently revealed that the vaccine, Pandemrix, can cause narcolepsy and cataplexy in about one in 16,000 people, and many more are expected to come forward with the symptoms.

Across Europe, more than 800 children are so far known to have been made ill by the vaccine.

Narcolepsy affects a person's sleeping cycle, leaving them unable to sleep for more than 90 minutes at a time, and causing them to fall unconscious during the day. The condition damages mental function and memory, and can lead to hallucinations and mental illness.

Cataplexy causes a person to lose consciousness when they are experiencing heightened emotion, including when they are laughing.

The Pandemrix vaccine was manufactured by pharmaceuticals giant Glaxo Smith Kline, which refused to supply governments unless it was indemnified against any claim for damage caused. The company will pay the bill, and claim the money back from the government.

"There's no doubt in my mind whatsoever that Pandemrix increased the occurrence of narcolepsy onset in children in some countries - and probably in most countries," Emmanuelle Mignot, a specialist in sleep disorder at Stanford University in the United States told Reuters.

Mignot has been paid by GSK to research the effects of the drug.

Among those affected are NHS medical staff, many of whom are now unable to do their jobs because of the symptoms brought on by the vaccine. They will be suing the government for millions in lost earnings.

However, the vast majority of patients affected - around 80% - are children.

Among them is Josh Hadfield, 8, from Somerset, who is on anti-narcolepsy drugs costing £15,000 a year to help him stay awake during the school day.

"If you make him laugh, he collapses. His memory is shot. There is no cure. He says he wishes he hadn't been born. I feel incredibly guilty about letting him have the vaccine," said his mother Caroline Hadfield, 43.

Despite a 2011 warning from the European Medicines Agency against using the vaccine on those under 20 and a study indicating a 13-fold heightened risk of narcolepsy in vaccinated children, GSK has refused to acknowledge a link.

"Further research is needed to confirm what role the vaccine may have played in the development of narcolepsy in those affected," the company said in a statement.

These NHS Staff were Told the Swine Flu Vaccine was Safe, and Now They're Suffering the Consequences

Buzz Feed News, 23 February 2018.
https://www.buzzfeed.com/shaunlintern/these-nhs-staff-were-told-the-swine-flu-vaccine-was-safe

Dozens of NHS workers are fighting for compensation after developing narcolepsy from a swine flu vaccine that was rushed into service without the usual testing when the disease spread across the globe in 2009. They say it has destroyed their careers and their health.

When nurse Meleney Gallagher was told to line up with her colleagues on the renal ward at Sunderland Royal Hospital, for her swine flu vaccination, she had no idea the injection she was about to have had not gone through the usual testing process.

It had been rushed into circulation after the swine flu virus had swept across the globe in 2009, prompting fears thousands of people could die. From the moment the needle broke Gallagher's skin, her life would never be the same.

"I remember vividly we were all lined up in the corridor and we were told we had to have it. It wasn't a choice," she claimed. "I was pressured into it. We were given no information."

The date was 23 November 2009 and Gallagher was one of thousands of NHS staff vaccinated with Pandemrix, a vaccine made by pharmaceutical giant GlaxoSmithKline (GSK).

Eight years later, her career in the NHS is a memory and she's living with incurable, debilitating narcolepsy and suffers from cataplexy, a sudden, uncontrollable loss of muscle tone that can cause her to collapse without warning. Because of her condition, she can no longer work or drive. People with narcolepsy experience chronic fatigue and difficulty sleeping at night. They can have night terrors, hallucinations, and a range of mental health problems.

Gallagher is not alone. More than a dozen frontline NHS staff are among around 1,000 adults and children across Europe who are believed to have developed narcolepsy after being given Pandemrix. Today BuzzFeed News can reveal for the first time their battle to gain acknowledgement for a government decision that they say ruined their careers and has dominated their lives since.

Gallagher and four other NHS professionals – two nurses, a community midwife, and a junior doctor – have told how they felt pressured into receiving the vaccine, were given misleading information, and ultimately lost their careers. They are all suing GlaxoSmithKline seeking compensation for what they believe was a faulty drug that has left them with lifelong consequences and means they will require medication and support for the rest of their lives.

They have been forced to take legal action, along with almost a hundred other sufferers, to force the company and the government to accept the consequences of the rushed vaccination programme eight years ago. In contrast to the UK, European countries have already compensated people whose narcolepsy was linked to the swine flu vaccine.

The revelations come the same day that health secretary Jeremy Hunt launched new measures to improve patient safety in the NHS, in response to research conducted by experts at the Universities

of Sheffield, Manchester, and York that showed prescription errors cause 1,700 deaths each year, could contribute to as many as 22,000 deaths, and cost the NHS £1.6 billion.

The BuzzFeed News investigation raises serious questions over the advice that was given to NHS staff at the time by the government's chief medical officer, the chief nurse, and the national flu director that the vaccine had been "thoroughly tested" and was safe to use. That advice was shared in a joint statement by the Department of Health (DH), medical royal colleges, and trade unions, including the British Medical Association and Unison.

Normally vaccines undergo testing to make sure they are safe, and vaccination has been proven to save millions of lives across the globe. But Pandemrix was different. It had not gone through the normal process and was fast-tracked without the usual clinical trials.

Staff were also not told that the government had agreed a unique deal with GSK to indemnify the company for any problems with the vaccine.

The investigation also turns the spotlight on decisions by the UK government to continue using the vaccine even after other European countries suspended its use once evidence of a problem emerged.

Peter Carter, then chief executive of the Royal College of Nursing, told BuzzFeed News it was "a matter of huge concern" that the vaccine had not been properly tested, contrary to what he was told at the time.

Meleney Gallagher was diagnosed in 2013 but only after years of being unable to stay awake and having cataplexy attacks several times a day, sometimes caused simply by laughing.

She switched jobs to be a district nurse, but the problems got worse. She said: "I was falling asleep in the clinic and driving home. I had cataplexy attacks when I was in the room with patients. I knew I wasn't safe to practise."

Although she sought help from occupational health services, her GP employer reported her to the Nursing and Midwifery Council and she was medically retired in April 2017. She received just 12 weeks' pay for 20 years' service in the NHS.

She said she had been denied an informed choice over the jab. "They can't just do what they want with vaccines, otherwise it's like Russian roulette and you can't do that. I just want someone to stand up and to say they were wrong and apologise. Someone to be sorry for what they have done. I feel really angry."

Gallagher's vaccination was part of a concerted effort by the Department of Health to immunise as many workers as possible. At the time, there was widespread global concern about the spread of the swine flu virus and fears it could replicate the Spanish flu of 1918.

While the concern was to save lives, it is alleged that senior figures in the department, including the chief nurse, chief medical officer, and national flu director, did not give a full picture of the vaccine.

A swine flu leaflet produced by the DH for staff and patients ahead of the nationwide vaccination said: "The European Commission carefully considered all the evidence and recommended that [the vaccine] could be used."

But it made no mention of the fact the European Medicines Agency had licensed Pandemrix under "exceptional circumstances" based on "mock vaccines" that did not include the actual ingredients that would eventually be injected into people. The EMA confirmed this approach was "unique to pandemic preparedness vaccines".

The DH leaflet also made no mention of the government's agreement to indemnify GSK for any problems with the vaccine. This was not widely known at the time, and the indemnity deal has never been published. In the summer of 2009, Wolf-Dieter Ludwig, chair of the German Medical Association's drug commission, had warned EU governments not to bear the risk for pharmaceutical companies.

Nationwide vaccinations started in the UK on 21 October 2009, despite the fact that experts at the DH had known since May the flu was milder than first thought. On 22 October, ministers agreed to revise down the worst-case scenario from 19,000 deaths to 1,000.

Ahead of the vaccinations starting, Dame Christine Beasley, then chief nursing officer for England, told Nursing Times: "We've gone through exactly the same procedures as we do with seasonal flu vaccine and it's as safe as a vaccine can be."

On the day immunisations began, the RCN's Peter Carter was quoted saying he was "entirely satisfied" the vaccine was safe because it had undergone "rigorous testing".

Carter told Buzz,Feed News: "At the time, Liam Donaldson, the chief medical officer, and Professor David Salisbury, the DH's director of immunisation, were assuring people this vaccine had been thoroughly and properly tested, so people like me, in good faith, had no reason to disbelieve that and were happy to encourage people to have the swine flu vaccine.

"It is a matter of huge concern that several years later it's now apparent this was not properly tested, and this will obviously shake the confidence of people for any future pandemic flu immunisation programmes. People have a reasonable expectation that what they are being told is accurate and it is a matter of regret that it clearly wasn't."

Salisbury told BuzzFeed News he believed a normal clinical trial would have been too small to pick up the problems with Pandemrix. "Given its rarity, any excess risk could only be detected after huge population exposure done through post-marketing surveillance," he said.

He declined to comment on staff saying they felt pressured or on issues around informed consent.

Sir Liam Donaldson did not respond to a request for comment.

NHS trusts received six letters between September and October alone urging them to vaccinate staff.

In November 2009, Ian Dalton, then national director for NHS flu resilience and now chief executive of NHS Improvement, wrote for the Health Service Journal that vaccinating staff was the "highest clinical priority". He stressed the need for staff to have information about "how it has been tested to ensure safety".

By 4 February 2010, it was clear swine flu was not going to be the catastrophe many had feared and ministers agreed not to extend vaccinations to the public. The NHS vaccination campaign went on because staff were considered a priority group.

Dalton wrote to trusts again saying he expected improvement in the uptake rate despite the "pre-dominantly mild illness". In an update for the Health Service Journal, he warned against complacency and said the programme was a "key governance responsibility" for NHS boards.

By April 2010, around 40% of the NHS frontline staff had been vaccinated with Pandemrix, which was more than double the seasonal flu vaccine uptake of 17% in 2008.

Among them were Hayley Best, an intensive care nurse working in Craigavon, Northern Ireland, and Shane Keenan, a senior emergency nurse practitioner in Oxford, who worked for 35 years in the NHS.

Both said they felt pressured to have the vaccine. Keenan said he felt it was "emotional blackmail", adding: "We weren't informed it wasn't properly trialled." Best agreed: "It wasn't that you were asked if you wanted it; you were told this was your appointment."

Keenan told BuzzFeed News that after he got the Pandemrix jab his life "started to fall apart… By early February [2010], I was having nightmares like you wouldn't believe and visual hallucinations."

Best said the effect on her was similarly dramatic, with severe suicidal thoughts within weeks.

Both said their symptoms were initially dismissed as depression and fatigue. Keenan was referred to specialists in December 2010. He struggled with work and was put through a capability assessment by his trust and moved down a pay band, decreasing his salary by £500 a month.

Eventually he realised he couldn't continue. "I was a potential danger to patients. I went to occupational health and suggested ill health retirement."

He said narcolepsy had "completely destroyed my life and my career. I worked damned hard to get to the pinnacle of my career. I lectured at Oxford University; now I can't even stack shelves. I was injured in the line of duty. NHS staff are collateral damage."

Best wasn't diagnosed until October 2014. She switched jobs to become a district nurse but still struggled. "It really came to a head in 2014 when I started falling asleep behind the wheel of my car. I just got to the point where I would have driven to somebody's house and not be able to remember doing it." She was medically retired in October 2016, just before her 40th birthday.

She said: "I was given a vaccine that wasn't properly tested. I am a big advocate for vaccination; my children have every vaccine that is offered.

"I was a good nurse, I know I was a good nurse. So where are my employers now? Where is my NHS? Where is my government? If you are going to encourage your frontline staff to have vaccines then the least you can do is have facilities in place if they happen to react to it. I feel completely betrayed. I have been abandoned. The NHS should have something in place if and when it goes wrong."

Not everyone had been convinced the vaccine was safe for use. Switzerland's medicine regulator Swissmedic refused to license it for use on under-18s in October 2009, and Michael Kochen, president of the German College of General Practitioners and Family Physicians, told the BMJ that same year that it had not been sufficiently tested to be declared safe.

The first hard evidence of a problem with Pandemrix emerged in 2010 when doctors in Finland noticed a dramatic increase in children with narcolepsy. Since then a number of studies in Europe and the UK have shown the vaccine is linked to an increased risk of narcolepsy in children and adults.

But even then, the Department of Health was not finished with the vaccine. While other European countries suspended its use in August 2010 due to the concerns, the UK used it to fill gaps in the seasonal flu jab supply in January 2011.

Professor Salisbury said at the time it was not a "second-class vaccine" and patients were "getting an effective vaccine and a safe vaccine".

According to the EMA, more than 980 people across Europe have been reported as developing narcolepsy because of Pandemrix, with 872 people reported as developing cataplexy, including more than 500 children.

More than 120 children and adults are believed to have been affected in the UK – some because of vaccinations that took place in winter 2010-11, after the first studies showing the side-effects had emerged and a year after the swine flu scare.

Around 100 UK families are suing GSK claiming the vaccine was a faulty product. Their law firm, Hodge Jones & Allen, declined to comment but the case has been ongoing since October 2013. It could result in a compensation bill as high as £100 million.

In 2016, judges ruled in favour of Josh Hadfield, who received a maximum £120,000 via the Vaccine Damage Payments Act after the Department of Work and Pensions (DWP), which administers the scheme, admitted Pandemrix caused Josh's narcolepsy when he was vaccinated aged 4.

His mother, Caroline, described the effect of the vaccine to BuzzFeed News: "He would like to have a bath on his own but he can't because there is a risk that he is going to fall asleep and drown. He is very introverted and doesn't like going out on his own because he is scared of what might happen.

"He sleeps two to four hours a day at school and that is when he is fully medicated. He has his own small bedroom at school. He doesn't have a normal childhood."

She added: "I am not saying all vaccines are bad and people shouldn't have them. It's the fact the government won't help people after something goes wrong."

During a parliamentary debate in March last year, Tracy Brabin MP accused the government of "foot dragging", which was "causing unacceptable and upsetting suffering and distress for the families involved".

She said in Sweden, Finland, Norway, Iceland, and France people who developed narcolepsy due to Pandemrix have already been compensated.

In 2014, 23-year-old nursery assistant Katie Clack died after jumping from a multi-storey car park. In a note to her family written on the day she died, she described the effects of narcolepsy as unbearable and urged her family to continue her legal action against GSK.

For the NHS staff who have developed narcolepsy, their ordeal has been compounded by being forced to battle with the health service and the government for recognition.

Junior doctor Ruth Tunney was in her third year of medical school on placement at Salford Royal Hospital when she volunteered for the vaccine.

"It was bundled in with the seasonal flu," she told BuzzFeed News. "I don't remember reading anywhere that it hadn't been tested. I didn't see anything that told me it was a different vaccine. It was a generic consent form."

She added: "I appreciate at the time they thought people were going to die and they had to act. I am completely pro-vaccination but they should acknowledge what has happened and do something about it rather than just denying it, which it feels is what is happening. It's changed my life for the worse forever."

Community midwife Susan Hamilton was formally diagnosed in 2012 after falling asleep while driving with her son. Her career was over, and six years on she faces having to sell her family home.

Hamilton said she tried reaching a compromise with her NHS trust but "was told categorically that they could not make a job for me and didn't have any obligation to make a job for me".

She said: "I have been forced out of my job because of a faulty drug and a trust who would not help me work around my condition or wait until I was stabilised on my medication. The NHS has abandoned us. We are damaged goods."

Like other staff, she said was not given information about the vaccine: "We weren't given a choice. It wasn't informed consent."

In response to this winter's severe seasonal flu there are increasing calls for NHS staff to face mandatory vaccinations. On Twitter, former NHS England and Department of Health medical director Sir Bruce Keogh responded to such calls by saying: "I think a serious debate around mandatory flu vaccination is inevitable before next winter."

Speaking to Buzzfeed News, Keogh said: "Every winter flu puts a significant strain on the NHS and a lot of people die. Both can be reduced with sensible vaccination programmes. A debate is emerging on how best to protect both vulnerable patients and staff in the NHS, particularly since there is such a big difference in vaccination rates between NHS organisations and over a third of flu is transmitted by asymptomatic people, meaning staff could unwittingly be spreading flu to their patients. No one wants that.

"Some people are in favour of mandatory vaccination, which could be across the board or only as a prerequisite for working in certain areas. Others are opposed on the basis of freedom of choice.

My sense is that staff should have their choice informed by evidence of benefit to themselves, their patients, and their organisation along with any potential personal risks or preferences.

"My view is that the focus on increasing staff vaccination rates should be on ensuring that organisations can demonstrate they have offered every single member of staff the chance to have a vaccine and made it easy for them to do so. This is what organisations with high vaccination rates do."

On the specific issues around Pandemrix and the lack of support for the staff affected by the vaccine, Keogh said: "It would seem both fair and reasonable and in keeping with the values of the NHS that if somebody suffers as a result of trying to do the right thing for others that they would be looked after appropriately."

Matt O'Neill, chair of Narcolepsy UK, a charity supporting some of the families affected, believes there should be a public inquiry into the use of the vaccines, what was known at the time, and how staff have been treated since.

He said: "NHS staff vaccinated with Pandemrix have been treated pretty disgustingly. Having a vaccination is an act you take on behalf of the community, for the benefit of the herd. When it goes wrong it makes sense that the herd should look after you."

"More staff would sign up for vaccines if they saw the NHS admit when it went wrong and that it supported staff. At some point, there will be another pandemic and we will need staff to have confidence they will be looked after if something goes wrong."

In 2010, Andy Burnham, the Labour health secretary at the time, and other ministers contributed to a review of the handling of the pandemic. It said: "[Management] personally would prefer to be criticised for doing too much rather than the alternative, where there could have been unnecessary deaths from doing too little."

Guy Leschziner, a consultant neurologist at Guy's and St Thomas' Foundation Trust, has treated a number of people who developed narcolepsy after having the swine flu vaccine.

On the use of Pandemrix, he told BuzzFeed News: "It's always easy with the benefit of hindsight. What we have to remember was what was going on at the time, which was that we thought we were going to have an epidemic of a very severe flu. Now today, knowing we didn't have quite the epidemic we thought we were going to have, you might come to a different conclusion, but at the time we didn't know that Pandemrix was associated with narcolepsy in comparison to the other vaccine."

GSK refused to answer questions from BuzzFeed News but issued a statement saying further research was needed to understand what role Pandemrix played in the development of narcolepsy. The company did not renew its licence and the vaccine is no longer authorised by the EMA.

Vaccine Safety

Narcolepsy Following 2009 Pandemrix Influenza Vaccination in Europe

CDC, 14 December 2022
https://www.cdc.gov/vaccinesafety/concerns/history/narcolepsy-flu.html

An increased risk of narcolepsy was found following vaccination with Pandemrix, a monovalent 2009 H1N1 influenza vaccine that was used in several European countries during the H1N1 influenza pandemic. This risk was initially found in Finland, and then other European countries also detected an association.

Background

Narcolepsy is a central nervous system disorder characterized by excessive daytime sleepiness (EDS) and abnormal manifestations of rapid eye movement (REM) sleep. This disorder is caused by the brain's inability to regulate sleep-wake cycles normally, but it can be treated with medication and behavior modification. About narcolepsy and other sleep disorders.
https://www.cdc.gov/sleep/about_sleep/key_disorders.html

Pandemrix is manufactured by GlaxoSmithKline in Europe and was specifically produced for pandemic 2009 H1N1 influenza. It was not used before 2009, and has not been used since the influenza pandemic season (2009-2010). It contains an oil-in-water emulsion adjuvant called ASO3. Adjuvants are substances added to a vaccine to increase the body's immune response to that vaccine. More about adjuvants. - https://www.cdc.gov/vaccinesafety/concerns/adjuvants.html

Pandemrix was not licensed for use in the United States

CDC Vaccine Safety Efforts and Research

In response to the events in Europe, CDC reviewed data from the U.S. Vaccine Adverse Event Reporting System (VAERS) and the Vaccine Safety Datalink (VSD) and found no indication of any association between U.S.-licensed H1N1 or seasonal influenza vaccine and narcolepsy.

In 2014, CDC published a study to assess the occurrence of narcolepsy following vaccination with 2009 H1N1 influenza vaccine or 2010-2011 seasonal influenza vaccine, both of which contained the 2009 H1N1 virus strain (more about types of influenza viruses). The analysis included more than 650,000 people who received the 2009 pandemic flu vaccine and over 870,000 people who received the 2010-2011 seasonal flu vaccine. The study found that vaccination with influenza vaccines containing the 2009 H1N1 virus strain used in the United States was not associated with an increased risk for narcolepsy.

Source: Narcolepsy and influenza A (H1N1) pandemic 2009 vaccination in the United States
https://pubmed.ncbi.nlm.nih.gov/25320099/

In 2018, a study team including CDC scientists analyzed and published vaccine safety data on adjuvanted pH1N1 vaccines (arenaprix-AS03, Focetria-MF59, and Pandemrix-AS03) from 10 global study sites. Researchers did not detect any associations between the vaccines and narcolepsy.

- Incidence rate study data did not show a rise in the rate of narcolepsy following vaccination except in the one signaling country included (Sweden, which used Pandemrix).

- Case-control analyses for Arepanrix-AS03 did not show evidence of an increased risk of narcolepsy.
- Case-coverage analysis for Pandemrix-ASO3 in children in the Netherlands did not show evidence of an increased risk of narcolepsy, but the number of exposed cases was small (N=7).
- Cases-control analysis for Focetria-MF59 did not show evidence of an increased risk of narcolepsy.

Chapter 8

Corruption Scandal around Experts and Advisors of WHO

Roadmap
of the Swine Flu Pandemic

Age of Autism

Dan Olmsted and Mark Blaxill

Voting Himself Rich:
CDC vaccine adviser made $29 million or more after using role to create market

Age of Autism, 16 February 2009, 05:45 AM
https://www.ageofautism.com/2009/02/voting-himself-rich-cdc-vaccine-adviser-made-29-million-or-more-after-using-role-to-create-market.html

Dr. Paul Offit of the Children's Hospital of Philadelphia (CHOP) took home a fortune of at least $29 million as part of a $182 million sale by CHOP of its worldwide royalty interest in the Merck Rotateq vaccine to Royalty Pharma in April of last year, according to an investigation by Age of Autism. Based on an analysis of current CHOP administrative policies, the amount of income distributed to Offit could be as high as $46 million.

There is nothing improper about receiving compensation for a patented innovation; but the extraordinary valuation placed on CHOP's patents raises concerns over Offit's use of his former position on the CDC's Advisory Committee on Immunization Practices to help create the market for rotavirus vaccine – to effectively vote himself rich.

Offit has steadfastly refused to say how much he made from the vaccine. Based on the income distribution guidelines set forth in CHOP's current administrative policy manual entitled "Patent and Intellectual Property Policy," Offit's share of this transaction - the "inventor's share of net income" - would have earned him a personal distribution of 30%. In a Moody's report dated June 2008, CHOP reported net proceeds from the Rotateq transaction of $153 million, a deal basis that would put the value of Offit's 30% share at $45.9 million. (manual) => www.rescuepost.com/files/chop-contract.pdf

Although the royalty transaction amounts and current CHOP inventor shares are publicly known, several factors complicate a precise calculation of Offit's income. Royalty Pharma paid $182 million for the Rotateq royalty stream, but CHOP reported proceeds of only $153 million. Since most universities calculate income based on net royalties, the lower number might more closely reflect the basis for calculating Offit's income. If CHOP applied an inventor share of 30% to a transaction value of $153 million they would have then been required to distribute $45.9 million to Offit.

CHOP's 30% policy for inventor share is consistent with the current practices of other children's hospitals. But depending on what standard was in effect when the patents were filed and how it was applied to Offit's proceeds, the amount could be lower. For example, the $29 million difference between the payment made by Royalty Pharma and the proceeds received by CHOP comprises 15.9% of the Royalty Pharma payment (15% is the lowest inventor share percentage we uncovered in our investigation) and could reflect the distribution to Offit,

So although it is clear that Offit's personal share of CHOP's royalty transaction was large, the exact amount could range from as little as $29 million to as much as $55 million. Age of Autism chose to feature the smaller amounts in this report.

CHOP spokeswoman Rachel Salis-Silverman, contacted by Age of Autism about Offit's income from the vaccine, first said, "I don't even know. That's not public information." She initially refused to provide an e-mail to which Age of Autism could send a detailed account of how it determined Offit's income, but subsequently sent an e-mail saying she was expecting the information.

"We are declining comment to your questions," she then replied after receiving our inquiry. Offit did not respond to an e-mail sent to his Children's Hospital address.

While refusing to disclose his personal profit from this transaction, Offit told Newsweek reporter Claudia Kalb last year that he got a "small percentage" of the payment and confessed that "it's like winning the lottery."

The $29 million-$55 million range is consistent not only with CHOP's published royalty arrangements but with typical medical patent standards:

- At Boston Children's Hospital, inventors get 25% of "net lifetime revenues" for all income over $500,000. For royalty amounts smaller than $500,000 inventors receive 45-100% of revenues.
- At Arkansas Children's Hospital, inventors get 35% of "net royalties" after the first $200K and 50% before that.
- At the University of Virginia, inventors get 15% of "total royalty income" over $1 million and a sliding scale of 25-50%for amounts smaller than that.
- At the University of California, inventors get 35% of "net royalties."

Offit's claim to a share of the profits from Merck's Rotateq revenues is based on his role as a listed inventor on the cluster of patents that protect Merck's vaccine. These patents share the title "Rotavirus Reassortant Vaccine" and include four granted US patents – US5626851, US5750109, US6113910 and US6290968 – and two granted European patents – EP323708 and EP493575.

All of the patents are jointly owned by CHOP and the Wistar Institute. Offit is one of the three listed inventors on the vaccine patents but holds 100% of CHOP's inventor rights. The other two inventors, Fred Clark and Stanley Plotkin, are both affiliated with the Wistar Institute (in a December 2005 transaction that was similar to CHOP's deal with Royalty Pharma, the Wistar Institute sold its royalty interest in Rotateq to Paul Capital for $45 million).

The CHOP policy manual that delineates the distribution of income for inventions owned by CHOP can be found (see section III B). Clearly, based on the distribution of income rights outlined in this manual, Paul Offit had a greater personal interest in Rotateq's commercial success than any other single individual in the world. And more than other individual in the world, he found himself in a position to directly influence that success.

Unlike most other patented products, the market for mandated childhood vaccines is created not by consumer demand, but by the recommendation of an appointed body called the Advisory Committee on Immunization Practices (ACIP). In a single vote, ACIP can create a commercial market for a new vaccine that is worth hundreds of millions of dollars in a matter of months. For example, after ACIP approved the addition of Merck's (and Offit's) Rotateq vaccine to the childhood vaccination schedule, Merck's Rotateq revenue rose from zero in the beginning of 2006 to $655 million in fiscal year 2008. When one multiplies a price of close to $200 per three dose series of Rotateq by a mandated market of four million children per year, it's not hard to see the commercial value to Merck of favorable ACIP votes.

From 1998 to 2003, Offit served as a member of ACIP. Before and during his ACIP term, Offit was involved in rotavirus vaccine development activities, the value of which ACIP influenced. Shortly before his term began in October 1998, Offit's first two rotavirus patents were granted by the U.S. Patent and Trademark Office, the first on May 6, 1997 and the second on May 12, 1998. During his ACIP term, Offit received two additional patents in 2000 and 2001.

Receiving a patent provides the potential but not the certainty of financial reward. In most cases, when an inventor's employer receives a patent, the commercial value of the patent award is highly uncertain. In the case of Rotateq, the business uncertainty revolved around three factors: 1) the creation and eventual size of the rotavirus vaccine market, 2) the market share of competing products such as Wyeth's RotaShield vaccine and 3) the success of Merck's clinical trial for Rotateq and subsequent FDA approval. For the first two of these three factors, Offit's ACIP membership gave him a direct opportunity to favorably influence his personal financial stake in Rotateq.

Four months before Offit was appointed to ACIP in October 1998, the committee had voted to give the rotavirus category a "Routine Vaccination" status, in anticipation of an FDA approval of RotaShield (oddly, ACIP made this vote before the FDA approved Wyeth's RotaShield vaccine on October 1, 1998). Shortly after Offit's term began, there were several additional votes involved in establishing the rotavirus vaccine market and Offit voted yes in every case. In May of 1999, the CDC published its revised childhood vaccination schedule and rotavirus vaccine was included. This series of favorable votes clearly enhanced the monetary value of Offit's stake in Merck's rotavirus vaccine, which was five years into clinical trials.

Nevertheless, Merck's Rotateq vaccine was several years behind Wyeth's RotaShield, which stood to be the market leader based on its lead in making its way through clinical trials. But when the widespread administration of RotaShield to infants started producing a high incidence of intussusception reports, including numerous fatalities, ACIP was forced to reverse itself. On October 22, 1999, ACIP voted to rescind its recommendation of the RotaShield vaccine.

Offit recused himself from this vote, although he participated in the discussion. In the meeting in which ACIP discussed RotaShield, Offit remarked, "I'm not conflicted with Wyeth, but because I consult with Merck on the development of rotavirus vaccine, I would still prefer to abstain because it creates a perception of conflict." CDC records make it clear that Offit was not silent on RotaShield. By 2001, he was actively advancing a "unique strain" hypothesis, an argument that RotaShield was formulated in a way that did increase intussusception risk whereas other formulations (e.g. Rotateq) would not.

In commercial terms, Offit had a clear stake in the earlier RotaShield decision. As a competitor to Rotateq, RotaShield's withdrawal provided a financial opportunity for Offit's partner, Merck. Not only did RotaShield's withdrawal give Rotateq an opportunity to gain 100% of the rotavirus vaccine market Offit had voted to create (until April 2008, when GlaxoSmithKline's Rotarix vaccine was approved, Merck held a monopoly on the rotavirus vaccine market), but the absence of competition enabled Merck to charge a premium price for its vaccine, significantly more than Wyeth had charged for RotaShield.

With RotaShield out of the market and the favorable rotavirus policy precedent established, when the FDA approved Rotateq on February 3, 2006, the path to profitability for Merck was set. And for CHOP, which had licensed its patent rights to Merck, the valuation of its patent portfolio soared. Faced with this newly valuable asset, CHOP chose not to take their profits in the form of a series of smaller royalty checks. Instead, they opted to sell off their rights to the income stream and receive a lump sum payment in its place. Royalty Pharma – an intellectual property investment firm that "provides liquidity to royalty owners and assumes the future risks and rewards of ownership" – stepped in to pay CHOP for the rights to its Merck royalties. CHOP, in turn, paid Offit his inventor share. Although neither CHOP nor Merck has disclosed Merck's royalty obligation around CHOP's patents, the fact that Royalty Pharma was motivated to pay CHOP $182 million for the right to receive the Rotateq royalty stream suggests that obligation was significant.

Other news organizations, most notably CBS News, have asked Offit to disclose the financial details of his Merck relationship. CBS New reporter Sharyl Attkisson wrote last July that, "future royalties for the [Rotateq] vaccine were just sold for $182 million cash. Dr. Offit's share of vaccine profits? Unknown." => https://www.cbsnews.com/news/how-independent-are-vaccine-defenders/

Offit protested loudly over the CBS News report and went so far as accusing Attkisson of unethical conduct. "Did [Attkisson] lie about whether or not we provided materials? Of course," Offit claimed in an August interview with the Orange County Register. He argued that in responding to a CBS News investigation of his financial ties to Merck, he readily provided full details of the payments that CBS asked for including: "the sources and amounts of every grant he has received since 1980"; "the details of his relationship, and Children's Hospital of Philadelphia's relationship, with pharmaceutical company Merck"; and "the details of every talk he has given for the past three years."

A personal profit of at least $29 million seems like more than a small detail to leave out.

Геннадия Онищенко:
«ВОЗ выступает в роли маркетингового отдела фирмы *Ля Роше*»

Интервью Руководителя Роспотребнадзора
Геннадия Григорьевича Онищенко

«Грипп А, H1N1, Калифорния/04/2009»

«Эхо Москвы», программа «В круге СВЕТА», 5 мая 2009
(стенограмма – https://46cge.rospotrebnadzor.ru/txt/4588)
Интервью целиком см. в разделе ' Criticism of WHO '

Гость: Руководитель Федеральной службы по надзору в сфере защиты прав потребителей и благополучия человека. Геннадий Григорьевич Онищенко

Ведущая: *Светлана Сорокина*

С. Сорокина: Здравствуйте, здравствуйте. Это программа «В круге СВЕТА». Сегодня в студии работаю я, Светлана Сорокина. И я сразу представлю вам моего собеседника. Это Геннадий Онищенко. Здравствуйте, Геннадий Григорьевич.

Г. Онищенко: Здравствуйте.
...

Г. Онищенко: Ну, на самом деле, его истинное название изначальное было – грипп А, H1N1, Калифорния, 04 2009. Это самое исконное, самое правильное его название. Потому что гриппов H1N1 по меньшей мере несколько тысяч уже было. За всю нашу совместную и неоднозначную историю сосуществования гриппа H1N1…
...

Г. Онищенко: Это была хорошо спланированная тогда информационная диверсия.

...
И наша *любимая ВОЗ*, которая является средоточием всего положительного, что есть у здравоохранения на этой планете, *выступает в роли маркетингового отдела фирмы «Ля Роше»*, которая совершенно случайно оказалась в той же Швейцарии, в том же городе Женева. Ну разве так можно?
...

С. Сорокина: Но близко к нему. Вопросы. Вот пишут о том, что где взять этот самый тамифлю, и еще реленса какой-то упоминают. Где это взять в аптеках?

Г. Онищенко: Так, первое – брать нигде не надо. Я вам просто настоятельно рекомендую – *не обогащайте на этом этапе наш фармацевтический бизнес*.

Пандемия лоббизма: На чем основаны обвинения Геннадия Онищенко в адрес Всемирной ассоциации здравоохранения и при чем тут бывший министр обороны США

Новая Газета, 8 мая 2009, 08:00
https://novayagazeta.ru/articles/2009/05/08/42921-pandemiya-lobbizma

Глобальный кризис забыт, рост цены на нефть не замечен: новости о распространении «свиного гриппа», для реабилитации свинины срочно переименованном в вирус H1N1, вышли на первые полосы газет. Всемирная ассоциация здравоохранения (ВОЗ) присвоила ему пятую (из шести) стадию угрозы, следующая – признание пандемии. Первой на угрозу пандемии откликнулась швейцарская компания F.Hoffman-La Roche.

Фирма передала Всемирной организации здравоохранения (ВОЗ) три миллиона упаковок антивирусного препарата «Тамифлю», который ВОЗ называет основным (а производитель – единственным) средством лечения «свиного гриппа». По сообщению компании La Roche, запасы препарата сделаны правительствами уже 85 стран мира и рассчитаны на 25–50% населения. Мир вздохнул облегченно, а котировки акций компании La Roche начали расти, явно опережая распространение самого гриппа.

И тут свое слово сказал главный санитарный врач России Геннадий Онищенко. Он заявил, что официальные представители ВОЗ не предоставили медицинским властям мира информацию о свойствах вируса H1N1, без которой нельзя создать вакцину против него, а вместо этого порекомендовали использовать препарат «Тамифлю», что, по словам Онищенко, «некорректно и противоречит уставу ВОЗ».

«Наша любимая Всемирная организация здравоохранения, которая является средоточием всего положительного, что есть у здравоохранения на этой планете, выступает в роли маркетингового отдела фирмы La Roche, которая совершенно случайно оказалась в той же стране – Швейцарии, в том же городе – Женеве. Разве так можно?» – заявил он в прямом эфире радио «Эхо Москвы» и добавил, что «Тамифлю», конечно, помогает, но кроме него существует «международная панель применяемых антиретровирусных препаратов».

Нельзя сказать, что мнению непримиримого борца с соседскими шпротами, боржоми и вином можно слепо доверять. Но, к сожалению, Онищенко не единственный, выдвигающий подобные упреки. Он просто пошел дальше, связав лоббистские усилия La Roche с деятельностью Всемирной ассоциации здравоохранения.

Вспомним историю препарата «Тамифлю». Это название стало широко известно в 2004 году, когда лекарство объявили эффективным против «птичьего гриппа». Заказы на него пришли из шестидесяти стран, в 2004-м доходы от продажи препарата увеличились почти в четыре раза и составили 44,6 млн долларов, а в 2005-м – 161,6 млн долларов. При этом информация, что вызвавший эпидемию неизвестный вирус аналогичен вирусу птиц, впервые прозвучала на пресс-конференции La Roche. Китайское «Бюро по контролю за оборотом

лекарственных средств» даже начало расследование ситуации, но ничего не добилось. Врачи подвергали сомнению действенность препарата, утверждая, что его принимали 70% умерших от «птичьего гриппа». Зато стоимость акций компании La Roche, продающей препарат, и его разработчика Gilead Sciences (получающего пятую часть средств от каждой проданной таблетки) резко выросла. А вот ценная информация для патриотов-сторонников теории заговоров: одним из акционеров Gilead Sciences был Дональд Рамсфелд, бывший министр обороны США. На пике угрозы эпидемии «птичьего гриппа» он, по данным налоговой декларации Рамсфелда за 2004 год, продал часть своих акций за 5 млн долларов и остался владельцем пакета еще на 25 млн.

Конечно, лоббизм «Тамифлю» – это скандальная версия. Понятно, ВОЗ важнее справиться с болезнью, чем оглядываться на предсказуемые обвинения в ангажированности, а фармацевтическая компания не может не воспользоваться угрозой пандемии для продвижения своего лекарства. И сделает это успешно: как сообщили «Новой» в сети аптек «36,6», препарат «Тамифлю» до недавнего времени не пользовался популярностью у покупателей, но за последние дни был полностью раскуплен.

В компании «Протек» (дистрибьюторе «Тамифлю») говорят об увеличении спроса на препарат со стороны аптек. Несмотря на цену в две тысячи рублей за 10 капсул, практически все запасы «Тамифлю» раскуплены. Как рассказывают в администрации сети аптек «Итек», паникующие люди скупают и другие противовирусные и профилактические средства, к примеру, арбидол и амиксин, а также марлевые маски для лица и дезинфицирующие средства для рук.

По словам Давида Мелик-Гусейнова, директора по маркетинговым исследованиям отраслевого агентства «Фармэксперт», до сих пор «Тамифлю» не считался ключевым продуктом компании, специализирующейся на дорогостоящих онкологических лекарствах. Но продажи антивирусного препарата выросли настолько, что он скоро может войти в пятерку самых продаваемых препаратов La Roche. «Проблема лоббизма фармацевтических средств встречается. Доказать его в случае La Roche сложно, но предсказать повышение прибыли компании можно уже сейчас», – говорит Давид Мелик-Гусейнов.

The Washington Times

Obama nominee omitted ties to biotech

The Washington Times, 9 September 2009
https://www.washingtontimes.com/news/2009/sep/08/obama-nominee-omitted-ties-to-biotech/

President Obama's nominee at the Department of Homeland Security overseeing bioterrorism defense has served as a key adviser for a lobbying group funded by the pharmaceutical industry that has asked the government to spend more money for anthrax vaccines and biodefense research.

But Dr. Tara O'Toole, whose confirmation as undersecretary of science and technology is pending, never reported her involvement with the lobbying group called the Alliance for Biosecurity in a recent government ethics filing.

THE FLU CASE

Obama bioterrorism nominee hides work for big pharma biodefense black op programmes

The Flu Case, 9 September 2009
https://web.archive.org/web/20090917152337/http://www.theflucase.com/index.php?option=com_content&view=article&id=532%3Aobama-bioterrorism-nominee-hide-involvement-with-big-pharma-and-black-op-programmes&catid=41%3Ahighlighted-news&Itemid=105&lang=en

Dr Tara O'Toole, who has been nominated by President Obama to take charge of bioterrorism in the Department of Homeland Security, worked as a key advisor to a group of pharmaceutical companies that lobbied the government for more money to develop bioweapons but omitted to report her work for the group in a recent government ethics filing.

The programme to channel money to pharmaceutical companeis to develop bioweapons was steered through the senate by Jay Rockefeller in 2003.

THE FLU CASE

Conflicts of interest at WHO's Global Advisory Committee on Vaccine Safety
Report in Chinese on the "swine flu" jab risks

The Flu Case, 9 September 2009
https://web.archive.org/web/20090917131846/http://www.theflucase.com/index.php?option=com_content&view=article&id=535%3Areport-in-chinese-on-the-qswine-fluq-jab-risks&catid=1%3Alatest-news&Itemid=64&lang=en

8. Conflicts of interest at WHO's Global Advisory Committee on Vaccine Safety (**GACVS**). The GACVS is touted by WHO as being an independent body with the members having "...impartiality and a high level of expertise..." => See:
https://web.archive.org/web/20040718005057/http://www.who.int/vaccine_safety/about/indepth/en/index.html

However, a quick check into the background of just one of the committee members (who was on the committee when GACVS largely dismissed the legitimate concerns about squalene's safety) reveals a different story.

Dr Kenneth Hartigan-Go is is listed as being the Executive Director of the The Zuellig Foundation in the Philippines. He was on the committee from June 2006 until June 1009. => See:
https://web.archive.org/web/20211112025612/http://www.who.int/vaccine_safety/about/current_members_june_2009.pdf

Also known as The Zuellig Family Foundation, this Foundation's logo is a modified version of that of Zuellig Pharma, a major supplier of pharmaceutical and vaccines in the Asia/Pacific region.
=> See: http://www.zuelligpharma.com/offices_china_pro&ser.html

What's more the Zuellig (Family) Foundation's website lists the League of Corporate Foundations (LFC) as a supporter of its work. http://www.zuelligfoundation.org/organizationalaffiliations_.htm A browse through the website of the LCF reveals that vaccine manufacturers Pfizer and Merck are LCF members. See: http://www.lcf.org.ph/content/directory-members

Thus it appears that far from being "impartial" when it comes to making decisions about vaccine safety, Dr Hartigan-Go is the Executive Director of a Foundation which has substantial links to the vaccine industry. I have not had time to look into the background of other members, but I would not be surprised if they had similar pharmaceutical industry links.

WHO makes the following claims for the **funding of GACVS**: "The work of the Committee is funded from multiple sources including WHO regular budget, UNICEF, the Bill & Melinda Gates Foundation, the GAVI Alliance and its Vaccine Initiatives. No funding is received from commercial organizations." =>
https://web.archive.org/web/20040704005030/http://www.who.int/vaccine_safety/about/indepth/en/index2.html

On the surface this funding sounds appropriately impartial, especially as WHO makes the claim that "commercial organisations" do not contribute funding to the committee. However, scratch the surface of this bland pronouncement and you will see it's actually quite deceitful. The Wikipedia entry on the GAVI [Global Alliance for Vaccines and Immunisation] Alliance, for example states:

"Launched in 2000 at the annual meeting of the World Economic Forum in Davos, the GAVI Alliance includes among its partners developing country and donor governments, the World Health Organization (WHO), UNICEF, the World Bank, the vaccine industry in both industrialised and developing countries, research and technical agencies, NGOs, and the Bill & Melinda Gates Foundation." http://en.wikipedia.org/wiki/GAVI_Alliance

Merck's website gives more detail on the GAVI Alliance and moreover states:
"Merck is a founding partner in the GAVI Alliance. Formed in 1999, GAVI is an unprecedented public/private partnership whose mission is to mobilize resources that support the widespread use of vaccines..." => https://web.archive.org/web/20100106235742/http://www.merck.com/corporate-responsibility/access/access-vaccines-immunization/initiatives.html

So, there we have it; the GAVI Alliance, one of the funders of WHO's Global Advisory Committee on Vaccine Safety (GACVS) is a "public-private partnership" (and an unprecedented one at that!) which states its "mission" as being "to support the widespread use of vaccines". Obviously, the widespread use of vaccines would benefit the vaccine manufacturers in this "public-private" partnership – and the widespread use of vaccines is not encouraged by candid disclosure of vaccine risks to the public. Even if none of the members of WHO's GACVS had links to the vaccine industry, the funding of GACVS by the GAVI Alliance could be sufficient compromise the committee's integrity.

While WHO states that GACVS committee members "must declare any conflict of interest" they also "sign a confidentiality agreement", presumably because they have access to unpublished data, which could damage vaccine company profits if unfavourable data were made public. This confidentiality agreement also means that there is no way for any honest doctor or scientist who may be on the committee to bring to the public's attention information that may be of vital interest to public health that may have been discussed – and whitewashed – in GACVS meetings. => See:
https://web.archive.org/web/20040718005057/http://www.who.int/vaccine_safety/about/indepth/en/index.html
https://web.archive.org/web/20040704005030/http://www.who.int/vaccine_safety/about/indepth/en/index2.html

abcNEWS

Drugmakers, Doctors Rake in Billions Battling H1N1 Flu

ABC News, 14 October 2009, 4:27 AM
https://abcnews.go.com/Business/big-business-swine-flu/story?id=8820642

Oct. 14, 2009. – Americans are still debating whether to roll up their sleeves for a swine flu shot, but companies have already figured it out: vaccines are good for business.

Drug companies have sold $1.5 billion worth of swine flu shots, in addition to the $1 billion for seasonal flu they booked earlier this year. These inoculations are part of a much wider and rapidly growing $20 billion global vaccine market.

"The vaccine market is booming," says Bruce Carlson, spokesperson at market research firm Kalorama, which publishes an annual survey of the vaccine industry. "It's an enormous growth area for pharmaceuticals at a time when other areas are not doing so well," he says, noting that the pipeline for more traditional blockbuster drugs such as Lipitor and Nexium has thinned.

As always with pandemic flus, taxpayers are footing the $1.5 billion check for the 250 million swine flu vaccines that the government has ordered so far and will be distributing free to doctors, pharmacies and schools. In addition, Congress has set aside more than $10 billion this year to research flu viruses, monitor H1N1's progress and educate the public about prevention.

Drugmakers pocket most of the revenues from flu sales, with Sanofi-Pasteur, Glaxo Smith Kline and Novartis cornering most of the market.

But some say it's not just drugmakers who stand to benefit. Doctors collect copayments for special office visits to inject shots, and there have been assertions that these doctors actually profit handsomely from these vaccinations.

It is a notion that Dr. Lori Heim, president of the American Academy of Family Practitioners, says is simply not true.

"According to most of the physicians I have talked to, the administration of these vaccines is done for the community's benefit as opposed to anything that helps profit," she says. Heim adds that even though doctors will not have to shell out for the H1N1 vaccine, they will bear the usual costs associated with storage and administering the shots.

"There is an administration fee, for the costs that you can't get reimbursed through Medicare or Medicaid," she says. "This is usually less than, or right at the break-even point."

Still, pharmacies also charge co-payments or full price of about $25 to those without insurance and often make more money if patients end up shopping for other goods.

"Flu shots present a good opportunity to bring new customers into our stores," says Cassie Richardson, spokesperson for *Supervalu*, one of the country's largest supermarket chains. Drawing customers to the back of a store, where pharmacies are often located, offers retailers a chance to pitch products that might otherwise go unnoticed.

Even companies outside of the medical industry are benefiting: the UPS division that delivers vaccines in specially designed containers, for example, has seen a bump in business.

New Entrants in Flu Shot Business

The intensifying competition has irked some doctors.

"Retailers and other non-medical professionals have siphoned off the passive income that once helped to cover medical overhead," says Dr. Caroline Abruzese, an internist in Atlanta. "The larger retail chains can invest up front in large volumes of vaccine at low prices, and market to customers already in their stores."

The promise of profits has attracted new players into the business. Some of the world's largest drugmakers, who in the past avoided the vaccine market because of its limited scope – its not easy to convince healthy adults to get a shot for measles – are now jumping into the fray.

Last month alone saw three large vaccine deals. Abbott Labs bought a Belgian drug business, along with its flu vaccine facilities, for $6.6 billion. Johnson & Johnson invested $444 million in a Dutch biotech firm that makes and develops flu vaccines. Merck, which already makes vaccines for shingles and other diseases, struck a deal to distribute flu shots made by Australian CSL.

Smaller biotechs are also angling for a slice of the action, making vaccines one of the fastest - growing areas of research in the biotech industry.

Large and small drugmakers are drawn to the business largely because of scientific advances that promise to radically expand the range of health problems that vaccines can address. In addition to preventing childhood diseases such as measles and polio, vaccines can now also ward off cervical cancer, and researchers are working on vaccines for HIV and tuberculosis.

Scientists believe they can create therapeutic vaccines than treat diseases such as Alzheimers and diabetes after they have set in. (At least one company is betting on a vaccine that helps cigarette smokers quit.)

"These innovations broaden the market potential for vaccine makers and partly explained the renewed interest by drugmakers," says Anthony Cox, a professor at Indiana University's Kelley School of Business who specializes in the marketing of medical products.

But Mark Grayson, a spokesperson for the Pharmaceutical Research and Manufacturers of America, which represents the country's leading pharmaceutical research and biotechnology companies, says that drugmakers are also compelled by the government to join efforts to ensure that there is enough vaccine to go around.

"Because of national security implications, the government felt that they needed to encourage and ask [vaccine manufacturers] to move much quicker," he says. Grayson adds that vaccine manufacturers also face significant costs; aside from the expense of fitting a new vaccine into a tight production schedule, drugmakers GlaxoSmithKline and Sanofi Pasteur were forced to acquire new vaccine production facilities in recent years to keep up with demand.

Alternatives to Vaccines Are Few

While this promise of new treatments for painful diseases brings hope to many, vaccines continue to attract critics. The National Vaccine Information Center, a non-profit advocacy group, is at the forefront of a movement demanding that vaccines be tested more thoroughly before hitting the market. Although there has been little evidence to support their claim, detractors -- including the comedian Jim Carrey – believe that vaccines are at least partly to blame for the sharp rise in autism in recent decades.

The swine flu vaccine has also attracted its share of critics. Frank Lipman, a New York-based doctor who specializes in a mix of Western and alternative medicine, points out that the swine flu is rarely fatal and that it's too early to tell if it's safe because it hasn't been widely tested.

Others argue that Americans have little choice. The cost of a widespread pandemic, similar to Spanish Flu outbreak in 1918, which killed 675,000 Americans (and 50 million worldwide), would be devastating. The Trust for America's Health, a Washington-based non-profit organization, estimates that a severe pandemic could push down GDP by more than 5 percent and cost Americans $683 billion.

"We're not seeing a pandemic that's this severe," says Jeff Levi, director of Trust for Americas Health. "We've dodged a lot of bullets."

Profit Driven Swine Flu Propaganda - Pump Up
Part I

Natural News, 21 October 2009
https://web.archive.org/web/20091024031833/http://www.naturalnews.com/027294_swine_flu_vaccines_H1N1.html

The pharmaceutical industry, with public health officials and the mainstream media acting as a mass marketing team, is about to pull off the biggest profiteering scheme in the history of the world. The swine flu hoax, perpetrated on a global level, will generate unheard of profits from a non-existent pandemic.

The Obama administration declared the spread of swine flu a public health emergency on April 26, 2009. The Associated Press reported that "Swine flu is now formally a pandemic, a declaration by U.N. health officials that will speed vaccine production and spur government spending to combat the first global flu epidemic in 41 years," on June 11, 2009.

"WHO chief Dr. Margaret Chan made the long-awaited declaration after the U.N. agency held an emergency meeting with flu experts and said she was moving to phase 6 – the agency's highest alert level – which means a pandemic is under way," the AP advised.

Since the "highest alert" warning was issued, the only estimation that has turned out to be true is that the drug companies are experiencing a windfall of tax dollars pouring into their coffers.

The US government "has committed $1.8 billion to companies to make a swine flu vaccine," Reuters reported on September 30, 2009, in an article with the headline, "Big pharma jumps back into flu business." => https://www.reuters.com/article/us-flu-vaccines-analysis-idUSTRE58S6AP20090930

"Three big U.S. pharmaceutical companies announced vaccine deals this week," Reuters noted, for companies that included Johnson & Johnson, Abbott Laboratories and Merck.

"Abbott Labs bought a Belgian drug business, along with its flu vaccine facilities, for $6.6 billion. Johnson & Johnson invested $444 million in a Dutch biotech firm (Crucell) that makes and develops flu vaccines. Merck which already makes vaccines for shingles and other diseases, struck a deal to distribute flu shots made by Australian CSL," ABC News reported on October 14, 2009

"Smaller biotechs are also angling for a slice of the action, making vaccines one of the fastest-growing areas of research in the biotech industry," ABC noted.

Dr Robert Belshe, director of Saint Louis University's Center for Vaccine Development, told Reuters that the US is on the verge of recommending that all citizens get a flu shot. "We're at 270 million people who should get vaccinated. It's a big market. I think manufacturers are just now catching up," he said.

"The vaccine market is booming. It's an enormous growth area for pharmaceuticals at a time when other areas are not doing so well," Bruce Carlson, a spokesperson for the market research firm Kalorama, told ABC News.

On October 1, 2009, under the headline, "Vical shares soar on Navy's H1N1 contract," Fierce Vaccines advised that: "Anyone doubting just how hot H1N1 news is right now should check out Vical's stock price this morning."

"The developer announced a modest $1.3 million contract with the Navy to fund the manufacturing and testing of its swine flu vaccine and the company's stock shot up 22 percent," the report said.

On September 29, 2009, Reuters noted that the H1N1 flu pandemic is not "the first flu outbreak to have lifted the shares of small vaccine makers."

"The H5N1 bird flu scare that began in 2005 fueled a similar rise," the reports said. "And the media statements issued by companies then are similar to many of those issued today."

"In May 2006, Vical, for example, announced that its bird flu vaccine protected mice and ferrets against H5N1," Reuters recalled. "This year, it said its H1N1 pandemic flu vaccine protected rabbits and mice. The news sent its shares soaring," the report noted.

Vaccine Makers Fund Studies

On September 10, 2009, MedPage Today ran the headline: "H1N1 Vaccines Safe, Immunogenic in Single Dose".

"Two investigational vaccines against the pandemic H1N1 flu appear to be safe and to yield a robust immune response with a single dose," MedPage reported.

"Those findings," it said, "contained in two preliminary reports published online today in the *New England Journal of Medicine* -- are reassuring, experts said."

The first report is from an Australian study supported by CSL and the Department of Health and Aging of the Australian government. "All authors report being employees of CSL and several report having an equity interest in the company," according to MedPage.

The second report is from a British study supported by University Hospitals Leicester and Novartis. Study leader, Dr Iain Stephenson, "reported financial links with Novartis Vaccines, Sanofi Pasteur, Baxter Vaccines, Hoffmann–La Roche, and GlaxoSmithKline," MedPage noted.

Profits Galore

On September 21, 2009, Reuters reported that the United States had ordered 222 million doses of H1N1 vaccine from five drug makers that include GlaxoSmithKline, Sanofi-Pasteur, Australia's CSL, AstraZeneca's MedImmune division and Novartis.

CSL has contracts to supply $180 million worth of bulk antigen to the US. Sanofi-Pasteur is providing more than 100 million doses to the US, in a $690 million order.

On September 25, 2009, MedImmune said it has "received a federal order for 29 million more doses of its nasal H1N1 flu vaccine, bringing its total order to more than 40 million doses, with a value of about $453 million," according to Gazette.net.

Seeking Alpha reported on August 24, 2009, that the "Swiss company Novartis received an order for $346 million for antigen and $343.8 million for adjuvant totalling $690 million in July."

The most recent estimates have GlaxoSmithKline "reaping some $4.8 billion from the pandemic, between its Pandemrix vaccine, its Relenza antiviral drug, and other products such as antiviral face masks and flu diagnostics," Fierce Pharma reported on October 9, 2009.

On June 11, 2009, Kalorama Information issued a press release with the headline, "New Report Forecasts More Than Doubling of Vaccine Sales by 2013."

The new report titled, "Vaccines 2009: World Market Analysis, Key Players, and Critical Trends in a Fast-Changing Industry," forecasts the market "to more than double by 2013 due to a strong pipeline of new products and rising usage of current products around the world," Kalorama wrote.

In the press release, Kalorama described 2008 as another "stellar year for the world vaccine market," in which sales "grew 21.5% since 2007 to reach $19.2 billion."

"Few areas of pharmaceuticals have seen the fast-moving developments in the marketplace that the vaccine market has," Kalorama noted.

Antiviral Drug Hype

On October 15, 2009, the Financial Times ran the headline: "Tamiflu boosts Roche sales figures," and reported that sales figures "were boosted by bumper demand for Tamiflu amid persistent fears about a global flu pandemic."

Tamiflu sales of $1.9 billion in the first nine months were more than four times ahead of the same period last year and third quarter sales figures were "nearly 10 times more than in the same period last year."

On July 22, 2009, Business Week reported that GlaxoSmithKline "expects to increase annual production of its inhalable anti-viral flu treatment Relenza threefold, to 190 million doses, by year end."

"Relenza sales for the three months ended June 30 were $99 million, up from just $5 million in the second quarter of 2008," the report noted.

The price of Tamiflu at a middle dose at DrugStore.com on August 26, 2009, was $93 for a packet of ten 75mg capsules. One inhaler of Relenza costs $64 at DrugStore.com.

Any good that will come from the swine flu propaganda campaign will accumulate solely with the profits of pharmaceutical industry.

Profit Driven Swine Flu Propaganda - Pump Up
Part II

Natural News, 22 October 2009
https://web.archive.org/web/20091024213605/http://www.naturalnews.com/027301_swine_flu_influenza_pandemic.html

This article is part two in a six-part series. Be sure to read part one at
https://web.archive.org/web/20091024031833/http://www.naturalnews.com/027294_swine_flu_vaccines_H1N1.html

Back on May 9, 2009, Robin Robinson, a director at the Department of Health and Human Services who oversees pandemic responses, told the Washington Post that even as officials take steps to develop a swine flu vaccine with sufficient doses for every "man, woman and child," those plans would be dialed back if the pandemic "fizzles out."

The pandemic has fizzled out but the gravy train toward vaccine profits is still rolling. On September 16, 2009, Reuters reported that the death rate from the pandemic H1N1 swine flu was likely lower than earlier estimates.

"Barring any changes in the virus, I think we can say we are in a category 1 pandemic. This has not become clear until fairly recently," said Dr Marc Lipsitch of Harvard, an expert in infectious diseases, told a meeting of flu experts convened by the US Institute of Medicine.

"The news is certainly better than it was in May and even better than it was at the beginning of August," he noted.

The US government's Pandemic Severity Index has five categories, with a category 1 comparable to a seasonal flu epidemic. Seasonal flu has a death rate of less than 0.1 percent, Reuters reports. A category 5 would compare to the 1918 flu pandemic, which had an estimated death rate of 2% or more.

Lipsitch gathered information on how many people had reported influenza-like illness around the world, which may or may not actually be influenza; government reports of actual hospitalizations and confirmed deaths, and "came up with a range of mortality from swine flu from 0.007 percent to 0.045 percent," Reuters advises. Having new information about how many people were infected and did not become severely ill or die makes the pandemic look very mild, Lipsitch said.

Minimal Swine Flu Deaths

The CIA World Factbook estimates the world population to be close to 6.8 billion and the US population a little over 307 million. At the beginning of the swine flu propaganda campaign, it was predicted that the strength of the pandemic could be measured by watching statistics from the Southern Hemisphere, where flu season runs from May to September, the southern autumn and winter months.

The Southern Hemisphere holds between 10 and 12% of the world's population, meaning the Southern Hemisphere population would be roughly 760 million people, at 11% of the world's total.

According to population numbers for 2008 from Nation Master.com, and statistics from the FluCount.org website, the total number of swine flu deaths, as of September 30, 2009, was only 2,386, for thirteen countries in the Southern Hemisphere, and three countries that are mostly in the Southern Hemisphere, with a total population of 628.3 million people who would have received no vaccine against the swine flu.

India's population of approximately 1.17 billion people amounts to about one-sixth of the world's population, according to the World Factbook. As of October 11, 2009, India's swine flu death toll was a mere 385, according to the Times of India.

On October 6, 2009, the Associated Press reported that the "CDC doesn't have an exact count of swine flu deaths and hospitalizations, but existing reports suggest the infection has caused more than 600 deaths and more than 9,000 hospitalizations since the virus was first identified in April."

=> https://www.nbcnews.com/id/wbna33196660

But yet the article further notes that "U.S. health authorities hope to give swine flu vaccinations to more than half the 300 million-plus population in just a few months."

=> https://www.nbcnews.com/id/wbna33190473

The first swine death in the army, the largest military branch with 552,425 soldiers, did not occur until September 10, 2009, according to the Associated Press on October 1, 2009. It was reported to be the only death among the 1.4 million men and women in uniform at that time.

=> https://www.sandiegouniontribune.com/sdut-us-army-swine-flu-100109-2009oct01-story.html

Yet all military personnel are required to receive the new swine flu vaccine. "The Pentagon has bought 2.7 million doses of vaccine, and 1.4 million of those will go to active-duty military personnel," the AP reported on September 29, 2009.

"National Guard troops on active duty are also required to receive the vaccine, as are civilian Defense Department employees who are in critical jobs," the article noted.

=> https://www.nbcnews.com/id/wbna33079725

In 2007, people under 20 years of age made up 27.6% of the US population, according to the US Census Bureau, meaning roughly 82.8 million people were under 20. At the end of September, the CDC was reporting only 76 deaths from swine flu among children in the US.

Dr Anne Schuchat, director of the agency's National Center for Immunization and Respiratory Diseases, told reporters that the number of pediatric deaths ranged from 46 to 88 during the past three flu seasons, which is hard to reckon with the fact that the CDC is always claiming that 36,000 people die of the seasonal flu each year in the US.

But then experts say the CDC's 36,000 flu death statistic, echoed by the media each year, is greatly distorted. In a 2006 paper in the "Journal of American Physicians and Surgeons," Dr David

Ayoub and Dr F Edward Yazbak report that a review of the mortality data from the CDC's National Vital Statistics System (NVSS) reveals "*these estimates are grossly exaggerated*."

(p. 43) => https://www.jpands.org/vol11no2/ayoub.pdf

The National Vitality Statistic System (NVSS) reports *preliminary mortality statistics* and distinguishes between influenza-related deaths and pneumonia-related mortality, they explain.

"When the final report is issued, influenza mortalities are combined with the far more frequent pneumonia deaths, yielding an exaggerated representation of "influenza" deaths," they report.

(p. 43) => https://www.jpands.org/vol11no2/ayoub.pdf

"Pneumonia related mortality due to immunosuppression, AIDS, malnutrition, and a variety of other predisposing medical conditions is therefore combined with seasonal influenza deaths," the doctors point out. "The actual influenza related deaths for the years 1997 to 2002 ranged from 257 to 1,765 annually," they advise. "These values are further overestimated by combining deaths from laboratory-confirmed influenza infections with cases lacking laboratory confirmation," they say. "There were fewer than 100 annual cases of viral-confirmed deaths during this same period. Deaths occurring in women of reproductive ages were rare, approximately one per year," they note.

(p. 43) => https://www.jpands.org/vol11no2/ayoub.pdf

On the CDC's main flu page they state that about 36,000 people die from the flu in the US each year. But if you search a little harder, he says, you find the actual number of people who died from the flu in 2005 was 1,805, the most recent data available.

"In 2004, there were just 1,100 actual flu deaths," Dr Mercola reports on his website. "The statistics the CDC gives are skewed partly because they classify those dying from pneumonia as dying from the flu, which is inaccurate," he says. See: https://www.omeonet.info/articles/flu_vaccine.htm

As of October 2, 2009, the World Health Organization was reporting only 4,108 swine flue deaths globally, five months into the pandemic, without any vaccines.

To put these numbers in perspective, consider that in 2005, more than 43,000 people died in motor vehicle accidents in the US, according to the Department of Transportation's National Highway Traffic Safety Administration.

Risks Outweigh Benefits

Studies also show flu vaccines do not work, and especially with children. On May 19, 2009, researchers at the International Conference of the American Thoracic Society in San Diego, presented a study that found children who received the trivalent inactivated influenza vaccine [TIV] had a three times greater risk of hospitalization for the flu than kids who were not vaccinated. See =>

=> https://www.sciencedaily.com/releases/2009/05/090519172045.htm

To determine whether the flu vaccine was effective in reducing the number of hospitalizations over consecutive flu seasons for 8 years, the researchers conducted a study of 263 children between the ages of 6 months and 18, evaluated at the Mayo Clinic between 1996 and 2006, with laboratory-confirmed influenza and reviewed records to determine which kids had received a flu shot before the illness and hospitalization.

According to the study, not only did the vaccine not prevent the flu, the children who received it got sicker than those who did not. Which means that for the 8 year period studied, health insurance companies, government programs and parents paid the cost of useless vaccines, doctors office calls and three times more flu-related hospitalizations, with the children suffering the harshest consequences.

On the "Healthy Skepticism" website, in a September 21, 2009 paper titled, "In the Face of Swine Flu, Common Sense and Science," Juan Gérvas, Honorary Professor, Public Health, School of Medicine, Autonomous University, in Madrid, Spain, reports that the "seasonal flu vaccine is relatively ineffective in children and adolescents, with a success rate of 33%, and is absolutely useless for children under 2 years." "There are doubts about how effective it is in preventing flu in adults and the elderly," he added. "We don't know anything about the effectiveness and safety of the swine flu vaccine which is ready to be marketed," Professor Gervas points out.

=> http://www.healthyskepticism.org/global/news/int/hsin2009-10

On April 29, 2008, Psychorg.com ran the headline, "Flu shot does not reduce risk of death," and reported that the "widely-held perception that the influenza vaccination reduces overall mortality risk in the elderly does not withstand careful scrutiny," according to researchers in Alberta, Canada.

=> https://www.sciencedaily.com/releases/2008/08/080829091323.htm

The study, published in the September, 2008, *American Journal of Respiratory and Critical Care Medicine*, a publication of the American Thoracic Society, included more than 700 matched elderly subjects, half of whom had taken the vaccine and half of whom had not.

"After controlling for a wealth of variables that were largely not considered or simply not available in previous studies that reported the mortality benefit, the researchers concluded that any such benefit 'if present at all, was very small and statistically non-significant and may simply be a healthy-user artifact that they were unable to identify.'," the report said. => doi: 10.1164/rccm.200802-282OC.

"Over the last two decades in the United Sates, even while vaccination rates among the elderly have increased from 15 to 65 percent, there has been no commensurate decrease in hospital admissions or all-cause mortality," said Dean Eurich, PhD, clinical epidemiologist and assistant professor at the School of Public Health at the University of Alberta.

"Further, only about 10 percent of winter-time deaths in the United States are attributable to influenza, thus to suggest that the vaccine can reduce 50 percent of deaths from all causes is implausible in our opinion," he advised.

=> https://www.reuters.com/article/us-flu-elderly-idUSHAR96014920080829

On May 2, 2006, the National Post reported that, "Canada's first experiment in universal, free flu vaccine has cost Ontario taxpayers more than $200-million, but appears to have done nothing to cut the spread of influenza," a new study suggests.

"The Ontario initiative, the world's first universal flu campaign, distributes about five million vaccine doses a year at a current cost of $50- to $55-million, including promotion," the Post said, citing the Health Ministry.

The highly publicized offer of free flu shots to all 12 million Ontarians was launched in 2000 to try to ease pressure on emergency wards from flu patients, and cut the incidence and severity of the illness, the Post noted.

"Per-capita flu rates in the province have not fallen at all since the program was introduced in 2000, concluded the University of Ottawa research, published in the journal Vaccine," the Post reported.

"In fact," the Post said, "the average monthly incidence of the virus jumped over the first five years of the program, though researchers say it is too early to say that numbers are really on the rise."

"All we do know is rates haven't decreased, and there has been a lot of money spent," said Dianne Groll, the University of Ottawa professor who led the study. "The program was designed to reduce the incidence of flu, and this hasn't yet happened."

Dr Groll looked at the number of cases of laboratory-diagnosed flu reported to Health Canada between 1990 and 2005, and found that the rate between 1990 and 2000, when the program started, was 109 per 100,000 Ontarians. Since the launch of the campaign, "it jumped to 164." the Post said.

It's worth noting that the study also found the Ontario flu rates did not change relative to other provinces.

Profit Driven Swine Flu Propaganda - Pump Up
Part III

Natural News, 23 October 2009
https://web.archive.org/web/20091024224849/https://www.naturalnews.com/027310_swine_flu_health_Tamiflu.html

This article is part three in a six-part series. Be sure to read part one and two at
https://web.archive.org/web/20091024031833/http://www.naturalnews.com/027294_swine_flu_vaccines_H1N1.html
https://web.archive.org/web/20091024213605/http://www.naturalnews.com/027301_swine_flu_influenza_pandemic.html

Public health officials now say they have quit keeping tabs on swine flu deaths because it is too difficult. A more likely explanation is that fear mongering would be impossible if they continued to announce the low rates of swine flu deaths and vaccine profits would take a nose dive.

"It's absurd to panic about swine flu, especially since it won't cause severe disease in many people," says Juan Gérvas, Honorary Professor, Public Health, School of Medicine, Autonomous University in Madrid, Spain, in the September 21, 2009 paper titled, "In the Face of Swine Flu, Common Sense and Science," on the Healthy Skepticism website. "The current WHO messages, which are increasing fear of swine flu is a form of disease mongering," he warns. "We need a health policy of common sense and self-control," Professor Gérvas advises. "The present messages by Governments, the WHO and the media focusing on the worst case scenario and the detailed description of each death is the completely wrong approach," he says.
=> http://www.healthyskepticism.org/global/news/int/hsin2009-10

On July 21, 2009, Spiegel Online interviewed epidemiologist, Dr Tom Jefferson, who has worked for the Cochrane Collaboration, an international team of scientists, for 15 years. "Sometimes you get the feeling that there is whole industry almost waiting for a pandemic to occur," Jefferson said.
He then listed the WHO, public health officials, virologists and the pharmaceutical companies. "They've built this machine around the impending pandemic," he said. "And there's a lot of money involved, and influence, and careers, and entire institutions!" "And all it took was one of these influenza viruses to mutate to start the machine grinding," Jefferson pointed out.
"It's true that influenza viruses are unpredictable, so it does call for a certain degree of caution," he advised. "But one of the extraordinary features of this influenza -- and the whole influenza saga," he said, "is that there are some people who make predictions year after year, and they get worse and worse." "None of them so far have come about, and these people are still there making these predictions," he pointed out. => http://www.spiegel.de/international/world/0,1518,637119,00.html
"For example," he asked, "what happened with the bird flu, which was supposed to kill us all?"
"Nothing," he said. "But that doesn't stop these people from always making their predictions."

Big Pharma Bonanza
On August 13, 2009, Dr Joseph Mercola, author of "The Great Bird Flu Hoax," explained how swine flu vaccine makers were set to profit by $50 billion. "According to Margaret Chan, Director-General of the World Health Organization (WHO), vaccine makers could produce nearly *five billion* pandemic flu shots per year in the best-case scenario," he wrote.

"And according to Business Week, wealthier countries like the U.S. and the U.K. will pay just under $10 per dose, while developing countries would pay less," he said. "If these facts hold true, Big Pharma stands to gain up to $49 billion a year on the swine flu vaccine alone."

=> https://web.archive.org/web/20090725053244/http:/www.businessweek.com/globalbiz/content/jul2009/gb20090722_800367.htm

As of 2009, "there has been no funding of a compensation program for children or adults injured or killed by vaccines or drugs used under an EUA (Emergency Use Authorization)," according to the National Vaccine Information Center.

In March 2008, Roche and Glaxo added new labels to Tamiflu and Relenza to warn of abnormal psychiatric behavior in some patients.

The drug makers said the revisions reflected recommendations made in November 2007 by an FDA advisory panel that reviewed the cases, which have been seen mostly in Japan. "At that meeting, FDA staff described reports of about 700 cases of psychiatric adverse events for both drugs and 25 pediatric deaths from various causes in patients taking Tamiflu, reported to the agency through May 2007. No fatalities were reported for Relenza," the Guardian reported on March 4, 2008.

=> https://jp.reuters.com/article/us-roche-fda/flu-drug-makers-change-labels-over-behavior-issue-idUSWBT00851720080304

On August 10, 2009, the Financial Times reported that the "medicine now being widely handed out by the government for treating pandemic flu offers only modest benefit in children and adults in seasonal outbreaks of the virus," according to British researchers.

=> https://www.ft.com/content/697f5f68-85c6-11de-98de-00144feabdc0

In an article in the British Medical Journal, a group led by Matthew Thompson at Oxford University said use in children under 13 of Tamiflu or Relenza reduced the duration of flu symptoms by an average of 12 to 36 hours with no decline in asthma or the need for antibiotics. The authors concluded that the drugs "provide a small benefit by shortening the duration of illness in children with seasonal influenza and reducing household transmission".

=> https://pubmed.ncbi.nlm.nih.gov/19666987/

"The findings came after a separate article published last week in Lancet Infectious Diseases, by researchers led by Jane Burch at the University of York, concluded that otherwise healthy adults showed a reduction in symptoms of just over half a day earlier when taking the drugs," the Gardian pointed out. => https://pubmed.ncbi.nlm.nih.gov/19665930/

On August 20, 2009, The Indepedent reported that the Oxford researchers said children should not be given Tamiflu or Releza to combat swine flu. They warned that Tamiflu could cause vomiting in some children, which could lead to dehydration and the need for hospital treatment.

Overall, "the researchers said, children who were otherwise healthy could suffer more harm than benefit from taking Tamiflu or another anti-viral, Relenza," the Independent advised.

=> https://www.independent.co.uk/life-style/health-and-families/health-news/don-t-give-tamiflu-to-children-1770154.html

Study co-author, Dr Carl Heneghan, a clinical lecturer at Oxford, said the current policy of giving Tamiflu for mild illness was an "inappropriate strategy". Dr Heneghan said the only benefit found in the study was that children were back to normal half a day to one day earlier if taking Tamiflu or Relenza. "The downside of the harms outweigh the one-day reduction in symptomatic benefits," he advised. "And he warned that widespread use of Tamiflu could result in the flu becoming resistant to the drug," the Independent reported.

Although the children in the studies analyzed were being treated for normal seasonal flu, Dr Thompson said the findings would extend to the current swine flu pandemic. "I don't think we have got any reason to think our results would be any different," he told the Independent. "The current swine flu is generally a mild flu illness...it does not seem that different from current seasonal flu," he said. "We would be happy to say our results apply to the current swine flu strain."

The research published in the BMJ "follows two recent studies which found that more than half of children taking Tamiflu suffered side-effects such as nausea, insomnia and nightmares," the Independent reported. Tamiflu was banned by the Japanese ministry in 2007 for use with 10- to 19-year-olds.

1976 Swine Flu Replay

As a kick-off to the 1976 swine flu propaganda campaign, Salon Magazine reports that in February 1976, F David Mathews, Secretary of Health, Education, and Welfare told Americans:

"There is evidence there will be a major flu epidemic this coming fall. The indication is that we will see a return of the 1918 flu virus that is the most virulent form of the flu. In 1918 a half million Americans died. The projections are that this virus will kill one million Americans in 1976."

On March 24, 1976, President Gerald Ford asked Congress to appropriate $135 million "for the production of sufficient vaccine to inoculate every man, woman, and child in the United States."

"I am directing the Secretary of HEW David Mathews, and Assistant Secretary, Dr. Cooper, to develop plans that would make this vaccine available to all Americans during the 3-month period from September to November of this year," he said. "I am asking each and every American to make certain he or she receives an inoculation this fall," Ford added."The reaction to the shot, I am told, may mean a few sore arms for a day or two--a very small price to pay for this vital protection," he advised.

The swine flu vaccination program began on October 1, 1976. Ten weeks later, after more than 40 million people were vaccinated, the government halted the program on December 16, 1976, due to the high number of severe adverse events occurring with the vaccine.

"The federal government ultimately reached court settlements and paid more than $90 million to hundreds of victims who said the 1976 vaccine caused neurological problems," according to a May 9, 2009 report in the Washington Post.

This time around, the Department of Health and Human Services "plans to eventually vaccinate at least 160 million people by December, with pregnant women, healthcare workers, children and young adults at the front of the line," Reuters reported on August 24, 2009.

Evelyn Pringle Profit Driven Swine Flu Propaganda - Pump Up
Part IV

Natural News, 27 October 2009
https://www.naturalnews.com/027336_swine_flu_health_propaganda.html

This article is part four in a six-part series. Be sure to read part one to tree at
https://web.archive.org/web/20091024031833/http://www.naturalnews.com/027294_swine_flu_vaccines_H1N1.html
https://web.archive.org/web/20091024213605/http://www.naturalnews.com/027301_swine_flu_influenza_pandemic.html
https://web.archive.org/web/20091024224849/https://www.naturalnews.com/027310_swine_flu_health_Tamiflu.html

Those in control of the mainstream media have joined together with public health officials to provide the pharmaceutical industry with the best swine flu promotional campaign that money can buy.

In an October 7, 2009, OpEd News article titled, "*The Centers for Disease Control*: The Best Vaccination PR Firm Taxes Can Buy," the makers of the documentaries, "Vaccine Nation," and "Autism: Made in the USA," Richard Gale and Dr Gary Null wrote: "If the flu season goes according to schedule, the vaccine industrial complex will be poised to join Wall Street for record year rip-off profits. We will also likely witness huge Pharma executive bonuses and perhaps gold-plated toilets.

"Even if the CDC statisticians' crystal ball used to forecast rampant swine flu infections turns into a complete bust – which would only be one more added to many other failed flu predictions back to 1976 – it will nevertheless be a very profitable failure as was the economic collapse for the banking cartel."

"In the US, such profits could never be accomplished without a dynamic, marketing initiative to convince Americans that vaccines will keep them protected and alive," they point out.

"And what better public relations machine for the vaccine complex, and all its supporters in health insurance and professional medical institutions, than our very own Centers for Disease Control and the Department of Health and Human Services?" they wrote.
=> https://prn.live/wp-content/uploads/2017/01/1-CDCBestPRFirmTaxes.pdf

The CDC is "formulating a $4.8 million multimedia campaign to encourage people to get vaccinated and help alleviate concerns and confusion, including radio and television public service announcements, print ads, and messages delivered via Twitter, RSS feeds and video podcasts on YouTube," according to the August 22, 2009 Washington Post. =>
https://www.washingtonpost.com/wp-dyn/content/article/2009/08/22/AR2009082202337.html?hpid=topnews&sid=ST2009082300274

Government health officials "are mobilizing to launch a massive swine flu vaccination campaign this fall that is unprecedented in its scope - and in the potential for complications," the Post reported. "The campaign aims to vaccinate at least half the country's population within months."

The federal government "has spent close to $2 billion to buy up to 195 million doses of vaccine and adjuvant," according to the Post.

"The government is prepared to buy enough to vaccinate every person – 600 million doses all together – if the pandemic or demand warrants it," the report said. "That could increase the cost to $5 billion for the vaccine alone."

"It would cost at least $9 billion to administer the vaccine to the entire population, according to the Association of State and Territorial Health Officials," the Post advised.

There is *nothing free about the flu vaccination* campaigns in the US. Americans will end up footing the bill in one way or another, along with the medical care for persons injured by the vaccine.

=> https://abcnews.go.com/Business/big-business-swine-flu/story?id=8820642

"As always with pandemic flus, taxpayers are footing the $1.5 billion check for the 250 million swine flu vaccines that the government has ordered so far and will be distributing free to doctors, pharmacies and schools," ABC News pointed out on October 14, 2009.

"In addition," the report said, "Congress has set aside more than $10 billion this year to research flu viruses, monitor H1N1's progress and educate the public about prevention."

On October 5, 2009, the Associated Press advised that the H1N1 vaccine itself is free because the government bought it with your tax dollars. "But providers can charge a small fee for administering it, usually about $20. Regular flu shots tend to cost up to $35," the AP said.

=> https://www.nbcnews.com/id/wbna33175413

Doctors are also set to profit greatly from administering the vaccines. The American Medical Association, which publishes Current Procedural Terminology (CPT), has even revised one CPT code and issued another for use in billing for H1N1 vaccines.

The changes "will streamline the reporting and reimbursement procedure for physicians and healthcare providers who are expected to administer nearly 200 million doses of the H1N1 vaccine in the U.S.," the AMA said in a statement.

=> https://www.infectioncontroltoday.com/view/ama-creates-new-cpt-codes-h1n1-flu-immunizations

Media as a PR Firm

"In too many ways, the mainstream media has become little more than a corporate mouthpiece, whoring itself out to the highest bidder / advertiser," warns Mike Adams, in the September 18, 2009, Natural News report titled, "Ten Swine Flu Lies Told by the Mainstream Media."

=> https://www.naturalnews.com/027055_vaccine_flu_swine.html

The "distorted reporting on the swine flu vaccine has been one of the greatest media frauds ever perpetrated," he says. "The media has in every way contributed to the widespread ignorance of the American people on the subject of vitamin D and natural immune-boosting defenses that could reduce swine flu fatalities," Adams points out.

"Rather than informing readers," he says, "the MSM has made it a point to keep the people stupid, and in doing so, the media has failed its only mission and betrayed the very audience it claims to serve."

Vested Interest in Spreading Swine Flu Propaganda

The media moguls controlling the MSM world-wide have a vested interest in hyping the swine flu epidemic to boost sales of vaccines and funding for the vaccine research industry.

Rupert Murdoch is a major shareholder, chairman and managing director of News Corporation. News Corp was the world's second largest media conglomerate, behind Walt Disney Company, as of 2008, and the world's third largest in entertainment as of 2009, according to Wikipedia, the online encyclopedia.

In late 2003, Murdoch acquired a 34 percent stake in Hughes Electronics, the operator of Direct TV, the largest American satellite TV system. In 2004, Murdoch announced that he was moving News Corp's headquarters from Australia to the US.

According to the Columbia Journalism Review, News Corp owns Fox Broadcasting Company and 27 Fox Television Stations in major cities all over the country, in addition to many cable channels, including the Fox News channel, and 20th Century Fox film companies and studios. News Corp also owns the New York Post, the Wall Street Journal and Dow Jones.

On February 2, 2009, GlaxoSmithKline announced the appointment of James Murdoch, son of media mogul Rupert Murdoch, as a non-executive director. Murdoch joined the company on May 20, 2009 and will also be a member of Glaxo's Corporate Responsibility Committee.

=> https://www.theguardian.com/media/2009/feb/02/james-murdoch-in-glaxosmithcline-role

Murdoch is Chairman and Chief Executive of News Corporation, Europe and Asia, and "has direct responsibility for the strategic and operational development of News Corporation's television, newspaper and related digital assets in Europe, Asia and the Middle East," Glaxo noted.

Murdoch is in charge of "News International, owner of four British newspapers – the Times, Sunday Times, Sun and News of the World," according to an article titled, "The Invisible Mogul: Meeting James Murdoch," by Sophie Barker, in the spring 2009 issue of "Intelligent Life Magazine." "His TV channels reach 200m people across 60-odd countries," Barker reports.

=> https://web.archive.org/web/20090225221711/http://www.moreintelligentlife.com/story/invisible-mogul

The Murdoch Children's Research Institute (MCRI) is the largest research Institute in Australia specialising in child and adolescent health. "Located on the campus of the Royal Children's Hospital, Melbourne, it is affiliated with the University of Melbourne," its website states.

Rupert Murdoch's mother, Dame Elisabeth Murdoch, is the widow of Australian newspaper publisher, Sir Keith Murdoch. She married Keith Murdoch, 23 years her senior, in 1928 and inherited the bulk of his fortune when he died in 1952. She was appointed a Dame Commander of the Order of the British Empire in 1963.

"It was through seed funding provided by Dame Elisabeth" in 1984, that the MCRI went on "to become the largest and most prestigious child health research centre in Australia," according to the February 7, 2009, Frankston Standard Leader. Elisabeth is a life-governor of the Royal Women's Hospital and a Patron of the Murdoch Children's Research Institute, according to the Australian Women's Register.

In 2009, MCRI has "over 1100 researchers," the Leader reports. Rupert Murdoch's daughter-in-law, Sarah Murdoch, has been the ambassador for the MCRI and a member of the development board since 2000.

The MCRI has six research themes, including one for "Infection, immunity and environment," with research conducted at the "Centre for Clinical Research Excellence in Child and Adolescent Immunisation."

The CCRE is a joint MCRI, Melbourne University, and Menzies School of Health Research collaboration whose secretariat is located in the Department of General Medicine at the Royal Children's Hospital campus.

"Research focuses on clinical trials of new vaccines in healthy infants, children and adolescents, the epidemiology of vaccine preventable diseases (VPDs) and evaluation of the impact of population-delivered vaccine programs, and mathematical modelling of vaccine-preventable diseases," the MCRI website advises.

Under "Collaborations," the site lists: "Promotion of collaborations with Australian and overseas immunisation researchers, policy-makers, service providers and the vaccine industry." Under a heading titled, "Commercialisation," the website states: "The Murdoch Children's Research Institute invites interested parties to take up the opportunity to invest in its wide portfolio of commercial biotechnologies."

In a July 27, 2009 press release, MCRI announced that children "are being recruited for a pandemic H1N1 swine flu vaccine trial set to begin in Melbourne next week." "About 100 Victorian children aged between 6 months to eight years are needed for the study, which will be run by the Murdoch Childrens Research Institute and the University of Melbourne from as early as next week," the press release stated.

"They will be among 400 children recruited across five states for the Federal Government required trials of the vaccine, produced by Australian biopharmaceutical company CSL," it advised. Four years ago, on October 4, 2005, the Murdoch Childrens Research Institute issued a similar press release

stating: "Bird flu vaccine trial to begin." "*Trials* of a bird flu vaccine are set to begin in Melbourne this week as researchers prepare against the threat of an influenza pandemic," MCRI advised.

"The study, a collaborative project between the Murdoch Childrens Research Institute and University of Melbourne, is being sponsored by Australian pharmaceutical company CSL Limited," the press release stated.

Media mogul, Mortimer Zuckerman, also has a research center named after him. On May 10, 2009, the New York Times reported that Zuckerman had "pledged $100 million to Memorial Sloan-Kettering Cancer Center, the largest donation in the hospital's history and one of the largest ever given to an American medical center."

=> https://www.huffpost.com/entry/ny-daily-news-owner-mort_n_20730

"Sloan-Kettering will name its new research center on the Upper East Side for Mr. Zuckerman, the real estate developer and owner of The Daily News and U.S. News & World Report," the Times noted.

=> https://www.nytimes.com/2006/05/10/nyregion/10gift.html

"Zuckerman advances vaccine research and development at the Mortimer B. Zuckerman Research Center in association with the Memorial Sloan-Kettering Cancer Center and Rockefeller University," according to Dr Leonard Horowitz, a Harvard-trained authority in vaccinations and emerging diseases with a masters degree in public health, in a September 30, 2009, report by Sherri Kane.

Zuckerman is also a leading financier of the American Lyme Disease Foundation that heavily promoted GlaxoSmithKline's disastrous Lymerix vaccine, Horowitz says.

"This vaccine was pulled from the market following hundreds-of-thousands of reported cases of recipients suffering post-vaccination symptoms of Lyme disease," he reports.

The great bird flu hoax serves as an excellent example of use of the MSM to pump out fear mongering propaganda. On June 20, 2005, Zuckerman wrote a commentary in US News and World Report titled, "A Nightmare Scenario – H5N1 Pandemic," and stated:

=> https://web.archive.org/web/20050622022123/http://www.nydailynews.com/news/ideas_opinions/story/320544p-274148c.html

"Should it develop certain genetic changes, international health experts warn, bird flu could spark a global pandemic, infecting as much of a quarter of the world's population and killing as many as 180 million to 360 million people – at least seven times the number of AIDS deaths, all within a matter of weeks."

"In the worst previous catastrophic pandemic, in 1918, more than 20 million died from the Spanish flu," Zuckerman wrote.

"We must prioritize research money to develop a vaccine, expand the production of flu vaccine, and stockpile antiviral medications," he advised.

On December 8, 2005, Bloomberg ran an article with the headline, "Bird Flu Pandemic May Cost U.S. Economy $675 Billion," in which Senate Majority Leader Bill Frist was quoted as saying, "A pandemic of bird flu in humans may cost the U.S. economy $675 billion, including lost work time and disruptions in supply chains."

This time around, on October 14, 2009, ABC News reported that "the Trust for America's Health, a Washington-based non-profit organization, estimates that a severe pandemic could push down GDP by more than 5 percent and cost Americans $683 billion."

=> https://abcnews.go.com/Business/big-business-swine-flu/story?id=8820642

"We're not seeing a pandemic that's this severe," says Jeff Levi, director of the group. "We've dodged a lot of bullets."

Last but not least, Thomas H Glocer is the Chief Executive Officer of the Thomson Reuters Corporation. On November 26, 2007, Merck announced that Thomas Glocer, Chief Executive Officer, Reuters Group PLC, "will join the Company's Board of Directors effective Nov. 27."

=> https://www.reuters.com/article/idUSWNAS3116/

"Merck currently discovers, develops, manufactures and markets vaccines and medicines to address unmet medical needs," the press release stated.

As shown above, the mainstream media cannot be objective when reporting on the swine flu because it is riddled with conflicts of interest involving the vaccine industry.

https://www.naturalnews.com/027336_swine_flu_health_propaganda.html

In the video commentary titled, *Mild Swine Flu & Over-Hyped Vaccine*, on the website for the National Vaccine Information Center, the group's co-founder and president, Barbara Loe Fisher, reports:

"We are witnessing a roll-out of the largest, most expensive mass vaccination campaign in the history of our nation. A rollout that is bigger than even the polio vaccine campaigns of the 1950's."

"If you or your child are injured from getting a flu swine flu shot, you are on your own," Fisher warns. "Because Congress shielded the vaccine manufacturers and any person giving swine flu shots from lawsuits if people get hurt," she says. "There is *no funded government vaccine injury compensation program* for swine flu vaccine."

"Doctors are telling some children under 10 years old to get 3 to 4 flu shots this year - 2 shots for seasonal flu and one or two more for swine flu," Fisher points out. "We have never given young children 3 to 4 flu shots in a single year and there is no information about how safe it is to do that," she advises.

On October 18, 2009, the Wall Street Journal advised that: "Children ages six months to nine years who have never received a flu vaccine before are recommended to receive two doses of both the H1N1 and seasonal-flu vaccine about a month apart," citing Paul Offit, chief of infectious disease at the Children's Hospital of Philadelphia, as the source, without letting readers know how rich he has become profiting off the vaccine industry.
=> https://www.wsj.com/articles/SB125582035965192331

Eight months ago, on February 16, 2009, "Age of Autism" published a report titled, "Voting Himself Rich: CDC vaccine adviser made $29 million or more after using role to create market," by Dan Olmsted and Mark Blaxil, for an investigation that found:
https://www.ageofautism.com/2009/02/voting-himself-rich-cdc-vaccine-adviser-made-29-million-or-more-after-using-role-to-create-market.html

"Dr. Paul Offit of the Children's Hospital of Philadelphia (CHOP) took home a fortune of at least $29 million as part of a $182 million sale by CHOP of its worldwide royalty interest in the Merck Rotateq vaccine to Royalty Pharma in April of last year."

"Based on an analysis of current CHOP administrative policies, the amount of income distributed to Offit could be as high as $46 million," the report noted.

"In a Moody's report dated June 2008, CHOP reported net proceeds from the Rotateq transaction of $153 million, a deal basis that would put the value of Offit's 30% share at $45.9 million," the authors wrote.

"Unlike most other patented products, the market for mandated childhood vaccines is created not by consumer demand, but by the recommendation of an appointed body called the Advisory Committee on Immunization Practices (ACIP)," the AoA report states. "In a single vote, ACIP can create a commercial market for a new vaccine that is worth hundreds of millions of dollars in a matter of months.

"For example, after ACIP approved the addition of Merck's (and Offit's) Rotateq vaccine to the childhood vaccination schedule, Merck's Rotateq revenue rose from zero in the beginning of 2006 to $655 million in fiscal year 2008," the authors explain.

"When one multiplies a price of close to $200 per three dose series of Rotateq by a mandated market of four million children per year, it's not hard to see the commercial value to Merck of favorable ACIP votes," the authors point out.

From 1998 to 2003, Offit served as a member of ACIP. As a member of the ACIP, Offit "voted to include the rotavirus vaccine in the Vaccines for Children program, which ultimately made his Rotateq product worth hundreds of millions of dollars to Merck," the National Autism Association reports.

Offit also holds a "$1.5 million dollar research chair at Children's Hospital, funded by Merck," according to a July 25, 2008 report by CBS News titled, "How Independent Are Vaccine Defenders?"

=> https://www.cbsnews.com/news/how-independent-are-vaccine-defenders/

Calling them "the most trusted voices in the defense of vaccine safety," CBS reports that the American Academy of Pediatrics, Every Child By Two, and pediatrician Dr Paul Offit, have something else in common - "strong financial ties to the industry whose products they promote and defend."

"The vaccine industry gives millions to the Academy of Pediatrics for conferences, grants, medical education classes and even helped build their headquarters," CBS found. Totals were secret, but documents cited by CBS reveal the following:

A $342,000 payment from Wyeth, maker of the pneumococcal vaccine - which makes $2 billion a year in sales. $433,000 from Merck, the same year the academy endorsed Merck's Gardasil vaccine - which made $1.5 billion a year in sales.

Another top donor was Sanofi Aventis, maker of 17 vaccines and a new five-in-one combo shot added to the childhood vaccine schedule in June 2008, CBS said.

"Every Child By Two, a group that promotes early immunization for all children, admits the group takes money from the vaccine industry, too - but wouldn't tell us how much," CBS investigative correspondent Sharyl Attkisson reports.

In April 2009, the AAP even filed a friend of the court brief (amicus) with the US Supreme Court in support of a petition for a writ of certiorari from vaccine makers Wyeth and GlaxoSmithKline to overturn a unanimous ruling by the Georgia Supreme Court that decided a civil lawsuit filed by Marcelo and Carolyn Ferrari on behalf of their autistic son was not barred by the National Childhood Vaccine Injury Compensation Act.

The Georgia decision noted that recognizing presumptive preemption would "have the perverse effect of granting complete tort immunity from design defect liability to an entire industry."

The Farrari family alleges that the vaccine makers could have manufactured safer childhood vaccines without the mercury-based, thimerosal, that caused their son's autism. The Georgia court's ruling would allow a jury to decide the case.

On September 9, 2009, the National Autism Association issued a press release with a headline: "Offit's Failure to Disclose Jeopardizes Swine Flu Vaccine Program," referring to his recent appearance on a segment of NBC's Dateline.

"As autumn approaches and millions of Americans consider taking an H1N1 Swine Flu vaccination, the integrity of all vaccine developers has been called into question by the financial relationship of a leading vaccine advocate and a pharmaceutical manufacturer," NAA advised.

"If people are to have confidence in the integrity of the Swine Flu vaccination program this fall then we need full disclosure of all financial relationships between proponents and manufacturers on every vaccine on the market," said Jim Moody, attorney for the NAA, in the press release.

"Who has an objective opinion about a company that has made them rich?" he said.

"Offit has zero credibility in matters of vaccine safety," says Wendy Fournier, president of the NAA. "Not only does he advance the absurd suggestion that children could safety get 100,000 vaccines at a time, he opposes any studies of the comparative health of unvaccinated children that could shed light on the extent and nature of vaccine-caused injuries, leading to their prevention."

Beyond Offit's financial conflicts, autism advocates are also dismayed about his credibility on speaking about autism in general, as he does not treat patients with autism.

"It's a mystery how such an inexperienced and financially conflicted man has become the go-to guy for information on autism," Ms Fournier says. "Here's a man with no real knowledge about autism that again and again appears in media coverage."

"Not only is he completely unqualified to address autism from a medical standpoint, his financial conflicts of interest disqualify him as a credible source for vaccine safety commentary as well," she points out.

Too many shots

"Today's immunization schedule now calls for kids to get 55 doses of vaccines by age 6," according to the CBS News report. => https://www.cbsnews.com/news/how-independent-are-vaccine-defenders/

The four flu shots recommended this year will be in addition to all the other vaccines children receive in complying with the mandatory childhood vaccine schedule.

On the "Age of Autism" website, Mary Podlesak warns that the flu vaccines still contain mercury. "I was reading the package inserts for the H1N1 vaccines from Novartis, Sanofi Pasteur and CSL last night," she said. "All three state the vaccine contains 25mcg of mercury – not 25mcg of thimerosal - 25mcg of mercury."

"When I checked the package inserts for the seasonal flu vaccine, they read the same as the H1N1 description," Podlesak wrote.

The package insert states: "The 5-mL multidose vial formulation contains thimerosal, a mercury derivative, added as a preservative. Each 0.5-mL dose from the multidose vial contains 25 mcg mercury."

Smaller amounts of thimerosal also remain in some other vaccines, even those marketed as "preservative-free," according to Age of Autism.

The H1N1 vaccine insert also states: "Pregnancy Category C: Animal reproduction studies have not been conducted with Influenza A"

"(H1N1) 2009 Monovalent Vaccine or AFLURIA. It is also not known whether these vaccines can cause fetal harm when administered to a pregnant woman or can affect reproduction capacity. Influenza A (H1N1) 2009 Monovalent Vaccine should be given to a pregnant woman only if clearly needed."

Back on May 20, 2003, after a three year investigation of pediatric vaccine safety, initiated in the US House Committee on Government Reform, the "Mercury in Medicine Report," was placed in the Congressional record.

"Thimerosal used as a preservative in vaccines in likely related to the autism epidemic," the report concluded.

"This epidemic in all probability may have been prevented or curtailed had the FDA not been asleep at the switch regarding the lack of safety data regarding injected thimerosal and the sharp rise of infant exposure to this known neurotoxin," the Committee advised.

"The FDA and the CDC failed in their duty to be vigilant as new vaccines containing thimerosal were approved and added to the immunization schedule," the report pointed out.

"At the same time that the incidence of autism was growing," the Committee said, "the number of childhood vaccines containing thimerosal was growing, increasing the amount of ethylmercury to which infants were exposed threefold."

Vaccine makers and conflicted public health officials are always claiming that studies show vaccines did not cause the autism epidemic. In a February 24, 2009 Huffington Post article, Robert F Kennedy, Jr, pointed out "that for sixty years the tobacco industry successfully defended a product that was killing one out of every five of its customers against thousands of legal actions brought by its victims and their families."

"Big tobacco prevailed for six decades," he said, "even without the help of supportive government agencies deliberately suppressing real science and research."

"In that sense vaccine victims must leap a much higher hurdle," he added.

https://www.naturalnews.com/027363_autism_vaccines_swine_flu.html

Most American are unaware that flu vaccines still contain thimerosal and that to avoid mercury, they have to ask for mercury-free shots. On November 13, 2007, the Milwaukee Journal Sentinel ran the headline: "*Most flu shots contain mercury*, but few know it."
=> https://www.dailycamera.com/2009/08/14/most-flu-shots-contain-mercury-but-few-know-it/
=> https://city.milwaukee.gov/ImageLibrary/Groups/healthAuthors/DCP/PDFs/grsThimVacc/JSArticleMostflushotscontainmercury.pdf

Thimerosal consists of 49.6% ethyl mercury. The Environmental Protection Agency and Food and Drug Administration have not set an exposure limit for ethyl mercury.

"The federal agencies have, however, set exposure limits for another organic and closely related form of mercury, methyl mercury - the type that comes from coal-fired power plants and is found in fish," the Journal said. "They use that standard when estimating the safety of ethyl mercury."
"A typical 0.5 milliliter flu shot contains 25 micrograms - or 50,000 parts per billion - of mercury," the Journal reported. "The EPA classifies a liquid with 200 parts per billion of mercury as hazardous waste," it advised. "The limit for drinking water is 2 parts per billion."

Using the standards set for methyl mercury consumption, "an average 130-pound person getting the flu shot would exceed the daily limit by more than four times," the Journal reported.
"A 22-pound baby would get more than 25 times the amount of mercury considered safe," it said.
"Mercury is among the most toxic heavy metals and is known to poison the central nervous system, liver, gastrointestinal tract and other systems in the body," the Journal reported.

When the influenza vaccines "are injected into pregnant woman and infants as young as six months, those vaccines contain 50,000 ppb mercury," warns Deirdre Imus in a November 19, 2007, Huffington Post article titled, "Over medicated and Over-Vaccinated: The Unintended Consequence of Medicines Meant to Protect."

This amount of mercury is 250 times higher than hazardous waste, she notes, and, according to EPA guidelines, this amount can only be considered safe if a person weighs 550 pounds. "Even trace amounts of mercury in vaccines can be anywhere from 600 to 2000 ppb," she advises.

People need to ask for a thimerosal-free vaccine if they want it, health officials told the Journal. "But many people aren't aware that mercury is in the flu shot," the Journal found.
"I didn't know," said Kate Strzok, a 23-year-old Oak Creek woman, as she walked out of the Piggly Wiggly where she had just gotten the flu shot. "Interesting that they don't tell you."

PutChildrenFirst.org, a parent-led organization advocating for vaccine safety, announced the results of a survey on November 13, 2006, conducted during October 27-30, 2006, by Zogby International of over 9,000 Americans, to learn their plans for getting flu shots, their knowledge of its ingredients, and who they held responsible for making sure vaccines are safe.

The survey showed that an overwhelming majority of Americans were unaware that most flu shots contained mercury. After learning that mercury was an ingredient, 74% of those polled said they were less likely to get a flu shot and 86% of parents said they were less likely to allow their children to get a shot.

"The survey reveals that Americans are overwhelmingly in the dark about what is in most flu shots," said Lyn Redwood, RN, MSN, president of SafeMinds, a nonprofit organization committed to ending mercury-induced neurological disorders, in a press release.

"They do not want a known neurotoxin injected into their children, and they believe Congress and medical professionals must be more vigilant about keeping vaccines safe and mercury-free," she advised.

"With everything we know about the dangers of mercury and the havoc it can wreak on young, developing brains," she said, "there is no excuse for any vaccine to contain mercury."

Lisa Handley is a founding parent of PutChildrenFirst whose son had an adverse reaction to a flu shot with mercury in 2003. "I know firsthand how life-changing a flu shot with mercury can be, since our son began his regression into autism after his flu shot," she stated in the press release.

Damning Reports

On October 5, 2009, the Maternal & Child Health Bureau of Health Resources and Services Administration, US Department of Health and Human Services released a study evaluating the number of children in the US who currently have a Autism Spectrum Disorder diagnosis, titled, "The Prevalence of Parent-Reported Diagnosis of Autism Spectrum Disorder among Children in the United States, 2007."

The study evaluated data from a national Survey of Children's Health and found that 1 in 91 children between the ages of 3 and 17 currently carry an ASD diagnosis.

"Even more alarming, for the subset of children between ages 6 and 14 immunized during the 1990's the prevalence is actually 1 in 71 children with an autism diagnosis," Age of Autism reports.

"This age group represents children in the U.S. with the highest exposure to thimerosal, the mercury preservative routinely used until CDC, AAP and industry recommended its removal "as soon as possible" from all childhood vaccines," AoA advises.

"We are especially alarmed by these findings because the seasonal influenza and H1N1 vaccines contain mercury well in excess of EPA safe exposure guidelines," said Theresa Wrangham, president of SafeMinds, in a statement to President Obama calling for a ban on mercury in vaccines given to pregnant women and young children.

Another new study found that giving Hepatitis B vaccine to newborn boys may triple the risk of developing an autism spectrum disorder. An abstract of the study was published in the September, 2009 "Annals of Epidemiology" journal. "Boys who received the hepatitis B vaccine during the first month of life had 2.94 greater odds for ASD compared to later - or unvaccinated boys," wrote Carolyn Gallagher and Melody Goodman of the graduate program in public health at Stony Brook University Medical Center in New York.

On September 30, 2009, Age of Autism Editor-at-Large, Mark Blaxill, reported on a new study in the journal "Neurotoxicology," by a research team led by scientists from the University of Pittsburgh and Thoughtful House, that found exposure to a birth dose of a hepatitis B vaccine that included thimerosal caused significant delays in the development of several survival reflexes in male rhesus macaque monkeys.

"In the first safety study of its kind of the hepatitis vaccine birth dose, the researchers showed that male macaques vaccinated at birth with a hepatitis B vaccine (HBV) took more than twice as long as unexposed macaques to acquire three standardized skills typically used to measure infant brain development," Blaxill wrote.

The study showed vaccinated monkeys learned more slowly to (1) turn their head in response to a brush on the cheek (root reflex); (2) open their mouth in response to a brush on the forehead (snout reflex); and (3) suck on a nipple placed in their mouth (suck reflex). The researchers found the unvaccinated monkeys developed normally.

The study is part of a larger research program looking at the safety of the vaccine schedule in children from birth to age four.

Dr Andrew Wakefield, Executive Director of Thoughtful House, and a co-investigator of the project, told Age of Autism that he found it particularly concerning "that in spite of the recommendation to remove thimerosal from vaccines a decade ago, millions of people, many of them children and pregnant mothers, are about to get mercury in their shots."

A 2006 study in the "Journal of American Physicians and Surgeons," by Dr David Ayoub and Dr F Edward Yazback, titled, Influenza Vaccinations During Pregnancy: A Critical Assessment of the Recommendations of the Advisory Committee on Immunization Practices (ACIP), states:

"The ACIP policy recommendation of routinely administering influenza vaccine during pregnancy is ill-advised and unsupported by current scientific literature, and it should be withdrawn. Use of thimerosal during pregnancy should be contraindicated."

"Because the benefits of influenza vaccination during pregnancy appear lacking, a safety-benefit analysis should not tolerate any risk to vaccine recipients or their offspring, even at a theoretical level," the doctors conclude.

Back on February 28, 2005, the Associated Press reported that lower "IQ levels linked to mercury exposure in the womb costs the United States $8.7 billion a year in lost earnings potential," citing a study by researchers at New York's Mount Sinai hospital published in the journal, "Environmental Health Perspectives."

The Mount Sinai Center for Children's Health and the Environment combined a number of previous studies to determine hundreds of thousands of babies are born every year with lower IQ associated with mercury exposure.

Lead researcher and pediatician, Leonard Trasande, reported that annually between 316,588 and 637,233 infants are born with umbilical cord blood mercury levels linked to IQ loss.

As an example, Dr Trasande said, each year about 4% of babies are with blood mercury levels between 7.13 and 15 micrograms per liter. That level of mercury causes an IQ loss of 1.6 points, the researchers concluded.

A 1.6 point drop could cost a person more than $31,000 in potential earnings over a lifetime due to missed educational opportunities or jobs, the study calculated. The researchers found the IQ losses linked to mercury ranged from one-fifth of an IQ point to as much as 24 points.

"The Environmental Protection Agency estimates that about 8 percent of American women of childbearing age have enough mercury in their blood to put a fetus at risk," the Associated Press noted.

WELT ONLINE

Transparency International kritisiert Profitdenken

Die Welt, 27 Oktober 2009, 10:56 Uhr
https://web.archive.org/web/20091031230028/http://www.welt.de/wissenschaft/schweinegrippe/article4990600/Transparency-International-kritisiert-Profitdenken.html

Die größte Impfaktion in der Geschichte der Bundesrepublik ist gestartet – und laut Transparency International sind dabei auch Geschäftsinteressen im Spiel: Experten, die über die Impfung entscheiden, hätten weitreichende, auch finanzielle Kontakte zu den Herstellern der Schweinegrippe-Impfstoffe.

Laut Transparency International ist bei der Massenimpfung gegen das H1N1-Virus auch von Geschäftsinteressen geprägt. So pflegten Fachleute enge Kontakte zu den Impfstoff-Produzenten. "Wir beobachten, dass da massive Interessenkonflikte sind", sagte Angela Spelsberg, Epidemiologin und Vorstandsmitglied der Anti-Korruptions-Organisation, dem Sender Deutschlandradio Kultur. Das Robert Koch-Institut (RKI) wies den Vorwurf zurück. Das Institut in Berlin berät die Bundesregierung bei der Impfaktion.

Spelsberg sagte, es gebe keine wissenschaftlichen Belege für eine große Gefahr durch die Schweinegrippe. "Die Impfaktion geht gegen eine Grippe vor, die im Vergleich zur saisonalen Grippe bisher ganz mild verlaufen ist." Die Ärztin kritisierte, dass es im Gesundheitswesen immer weniger unabhängige Experten gebe. Bei der Schweinegrippe gelte für maßgebliche Fachleute, "dass sie zum Teil in die Impfstudien selber involviert sind und dass sie von den Herstellern der Impfstoffe finanzielle Unterstützung erhalten beziehungsweise Honorare bekommen".

RKI-Sprecherin Susanne Glasmacher sagte dazu: "Die Arbeit auf dem Gebiet des Impfens bringt natürlich auch Kontakte zu den Herstellern mit sich." Die Mitglieder der Ständigen Impfkommission beim RKI müssten jedoch vor ihrer Berufung und vor jeder Sitzung Auskunft über mögliche Interessenkonflikte geben. "Das wird auch überprüft. Insofern denken wir, dass da transparent informiert wird." Wer befangen sei, dürfe bei entsprechenden Tagesordnungspunkten nicht mit abstimmen.

Auch das Nachrichtenmagazin "Der Spiegel" hatte bereits über enge Kontakte des RKI-Fachgebietsleiters Walter Haas zu Herstellern der Schweinegrippe-Impfstoffe berichtet. Der Arzt koordiniert die RKI-Pandemiplanung und ist Mitglied im wissenschaftlichen Beirat der European Scientific Working Group on Influenza (ESWI), die von zahlreichen Pharma-Unternehmen unterstützt wird, darunter der Hersteller des in Deutschland eingesetzten Impfstoffs Pandemrix, GlaxoSmithKline.

Glasmacher sagte, die Tätigkeit beinträchtige Haas' Unabhängigkeit als Mediziner nicht. "Er berät die ESWI unentgeltlich und im Auftrag des Robert Koch-Instituts." Der Mediziner bringe lediglich als Berater seine Exerpertise ein, diene aber nicht wirtschaftlichen Interessen.

Indessen läuft die größte Impfaktion in der Geschichte der Bundesrepublik vielerorts nur schleppend an. Vor allem in den bevölkerungsreichsten Bundesländern Nordrhein-Westfalen und Bayern meldeten viele Praxen geringes Interesse für die Immunisierung gegen Schweinegrippe.

Zwar waren zumeist vor allem Berufsgruppen wie Ärzte, Schwestern, Rettungskräfte und Polizisten zu der freiwilligen Aktion aufgerufen. In einigen Ländern konnten sich aber bereits alle Patienten impfen lassen.

Bis Mitte der Woche soll die Impfung im ganzen Bundesgebiet angelaufen sein. Nach dem so genannten Schlüsselpersonal kommen auch chronisch Kranke und dann jeder andere Impfwillige an die Reihe. Experten riefen zur Teilnahme auf und warnten zugleich vor den Folgen von Impfmüdigkeit.

Die geplante bundesweite Immunisierung hatte schon vor Beginn für großen Wirbel gesorgt: Hintergrund sind Wirkstoffverstärker, die die Spritze weniger verträglich machen können als normale Influenza-Impfungen. Außerdem wurde bekannt, dass die Bundesregierung für Spitzenpolitiker, hohe Bundesbeamte und Soldaten einen Impfstoff bestellt hat, der anders als der für die Normalbevölkerung keine Verstärker enthält.

Der Berufsverband Deutscher Internisten warnte vor den Folgen einer generellen Impfmüdigkeit. Verbandspräsident Wolfgang Wesiack warf der Regierung ungeschicktes Vorgehen vor, mit dem sehr viel Vertrauen in der Bevölkerung verspielt worden sei: "Das kann ein Millionen-Flop werden", warnte er.

THE FLU CASE

Transparency International:
"Swine Flu Vaccination Campaign Motivated by Profit!"

The Flu Case, 30 October 2009, 10:11
https://web.archive.org/web/20091103112437/http://www.theflucase.com/index.php?option=com_content&view=article&id=1479%3Atransparency-international-qswine-flu-vaccination-campaign-motivated-by-profitq&catid=41%3Ahighlighted-news&Itemid=105&lang=en

Transparency International has criticised the swine flu vaccination campaign, saying that it is motivated by profit, according to a report in Die Welt.

Health experts who had a key role in mandating the swine flu vaccination campaign have financial links to the pharmaceutical companies producing the jab, epidemiologist Angela Spelsberg said.

"We observe that there are massive conflicts of interest," she said.

Spelberg said there was no evidence that the swine flu was dangerous to people.

She said man of the medical experts involved in developing the swine flu vaccine have financial connections to the pharmaceutical companies.

The Spiegel magazine reported that Walter Haas, the doctor who coordinated the country's pandemic plan has close links to GlaxoSmithKline, the company producing the Pandemrix vaccine planned for use in Germany.

Les multiples casquettes du professeur Lina

le Parisien, 29 October 2009, 07:00 h
https://web.archive.org/web/20091101134155/http://www.leparisien.fr/societe/les-multiples-casquettes-du-professeur-lina-29-10-2009-691695.php

C'est l'exemple type des relations ambiguës que peuvent entretenir médecins, pouvoirs publics et laboratoires pharmaceutiques. Le Groupe d'expertise et d'information sur la grippe (Geig), créé en 1979, se présente comme une association régie par la loi de 1901, doté d'un conseil scientifique de quinze membres qui, comme bon nombre d'autres groupes d'influence, distillent ses recommandations au petit monde de la santé.

La menace d'une pandémie de grippe A a placé ces dernières semaines le président de son comité scientifique, Bruno Lina, sous le feu de la rampe. Ainsi, le 20 octobre, à l'occasion du lancement officiel de la campagne de vaccination de la grippe A au ministère de la Santé, le professeur Lina était invité à s'exprimer, assis à la gauche de Roselyne Bachelot. Il a notamment répété qu'il était « très important de se faire vacciner » contre ce virus.

Contrairement à ce qu'il revendique sur son site Internet, le Geig n'est toutefois pas ce qu'on peut appeler une association indépendante. Selon nos informations, ce groupe est en effet financé à 100 % par cinq laboratoires pharmaceutiques qui produisent des vaccins contre la grippe. Son directeur général n'est autre que Bertrand Verwee, le directeur marketing de Sanofi-Pasteur-MSD, le département vaccin du géant pharmaceutique français. «Effectivement, nous finançons le Geig, reconnaît Bertrand Verwee. Sanofi-Pasteur-MSD prend à son compte 50 % du budget annuel du Geig, qui s'élève à 400 000 €. Le reste est réglé par quatre autres laboratoires également producteurs de vaccins contre la grippe: GSK, Novartis, Pierre Fabre et Solvay.»

« Je ne vois pas où est le problème »

Dès lors, le risque de conflit d'intérêts est manifeste lorsque le professeur Lina s'exprime publiquement sur la vaccination contre la grippe saisonnière ou la grippe A, car il multiplie les casquettes. Il est à la fois professeur de médecine au CHU de Lyon et « expert auprès du ministère de la Santé pour le risque pandémique », comme il le revendique sur la jaquette de son récent livre où il promet « la Vérité sur la grippe A ». Il est encore membre du comité de lutte contre la grippe, organisme officiel rattaché au ministère de la Santé, et enfin conseiller de Margaret Chan, la directrice de l'Organisation mondiale de la santé pour le risque pandémique. «C'est vrai que j'ai différentes casquettes, mais je l'assume, se défend Bruno Lina. J'ai des collaborations, que je ne cherche pas à cacher, avec les laboratoires Roche, Sanofi, GSK et BioMérieux. Je ne vois pas où est le problème. Je suis très demandé, car j'ai publié des travaux importants sur la grippe. Les rencontres du Geig me permettent d'échanger avec mes collègues, mais je ne suis pas rémunéré par cette structure. » Et d'asséner: « Lorsque je donne un conseil à la ministre de la Santé en matière de stratégie de vaccination contre la pandémie, je garde toute mon indépendance.»

Le cabinet de Roselyne Bachelot, sollicité hier, se montre, lui, plus embarrassé. «Nous avons sollicité ce professeur, car c'est un des meilleurs experts sur le sujet. Nous savons qu'il est directeur scientifique du Geig. Mais ce n'est pas à ce titre qu'il s'exprime aux côtés de la ministre.» Quant à la question du financement du Geig par les laboratoires, elle ne donne lieu qu'à un silence gêné.

Conflicts of interest?
Dr. Mehmet Oz owns 150,000 option shares in vaccine technology company

Natural News, 10 November 2009.
https://www.naturalnews.com/027451_vaccine_RealAge_technology.html

Dr. Mehmet Oz is a huge promoter of vaccines. He's been on television reinforcing fear about H1N1 swine flu and telling everyone to get vaccinated. But what he didn't tell his viewing audience is that he holds 150,000 option shares in a vaccine company that could earn him millions of dollars in profits as the stock price rises. It is in Dr. Oz's own financial interest, in other words, to hype up vaccines and get more people taking them so that his own financial investments rise in value.

Evidence describing these facts was delivered to NaturalNews by a private investigator named Joseph Culligan (http://webofdeception.com/oprah.html#oz). That evidence includes an SEC document detailing how Dr. Oz. bought options on stocks for SIGA Technologies in 2005, 2007, 2008 and 2009. SIGA Technologies (stock symbol SIGA) is a vaccine technology company with many advanced developments whose success depends on the widespread adoption of vaccines. According to SEC documents, Dr. Mehmet Oz. currently holds 150,000 option shares on SIGA Technologies, purchased for as little as $1.35 back in 2005.

At the time of this writing, SIGA Technologies is trading at $7.10, making those options bought in 2005 worth $5.75 in profits today. If all the 150,000 options purchased by Dr. Oz. were exercised today, they would be worth roughly $180,000 in profits (they were bought at different prices, not all at $1.35). This is all revealed in what the SEC website calls an "insider transaction" document (link below).

These options won't expire until the years 2015 - 2019, and the higher the stock price of SIGA gets before then, the more profit can be realized when these options are cashed out. You can see the 2019 expiration date in this "insider transaction" form:
https://www.sec.gov/Archives/edgar/data/1010086/000114036109012259/xslF345X03/doc1.xml

If the stock price of SIGA Technologies could be pumped up even more -- say, from someone hyping up vaccines in front of a national audience -- these options could mathematically be worth millions of dollars. Just to clarify, by the way, SIGA Technologies doesn't currently manufacture a vaccine for H1N1 swine flu. It focuses on future vaccine technologies that could be applied to many different vaccines down the road.

Dr. Oz. isn't merely a holder of SIGA stock options, by the way: He's on the Board of Directors! As SIGA's own website explains, Dr. Oz has served on the board since 2001 and continues his role there today. This brings up the obvious question:

Is it right for someone talking about whether vaccines are safe on television to also be carrying stock options and serving on the board of directors of a vaccine company at the same time?

Just to make things a little more interesting, SIGA Technologies recently received a $3 million grant in taxpayer dollars from the National Institutes of Health (NIH). The purpose of the grant money? To fund the study of a chemical adjunct named ST-246 to be used in future vaccines. So taxpayer money is now being used to fund a vaccine technology company whose stock price increases will financially benefit the very celebrity doctor who is hyping up vaccines to a national audience.

Something sounds fishy here...

Conflict of interest?

To my knowledge, Dr. Oz. has never disclosed to his viewing audience the fact that he owns 150,000 option shares of SIGA Technologies. And yet, with an audience of millions, Dr. Oz has continued to beat the drum of the vaccine industry, urging people to get vaccinated while implying that vaccines protect people from swine flu (even though there is absolutely no scientific evidence to back up that claim).

Here's a link to the SEC document detailing Dr. Oz's ownership of these 150,000 option shares:
https://www.sec.gov/cgi-bin/own-disp?action=getowner&CIK=0001139299&sortid=period-of-report-ASC

The current value of SIGA shares can be verified here:
http://finance.yahoo.com/q?s=SIGA

Information about SIGA Technologies and their vaccine technology can be found on their website:
http://www.siga.com/index.php?ID=2

The press release announcing SIGA's receipt of $3 million from the NIH is available here:
http://www.siga.com/?ID=120

The RealAge Big Pharma front group

In addition to holding stock options in a vaccine technology company, Dr. Oz. is also a front man for the RealAge website, a sort of "health front group" for the pharmaceutical industry that uses information provided by RealAge members to solicit consumers with pro-pharma marketing message targeted by age or health condition.

Corporate sponsors of RealAge include most of the major drug companies and their most profitable pharmaceutical products such as Adderall, Ambien and Celebrex. The companies sponsoring RealAge include GlaxoSmithKline, Genentech, Wyeth and many others. RealAge is essentially a marketing platform for Big Pharma, disguised to look like a consumer health information service.

The New York Times calls RealAge "a window for drug makers" and explains, "The test has received widespread publicity because of its affiliation with Dr. Mehmet Oz."
https://www.nytimes.com/2009/03/26/technology/internet/26privacy.html?_r=2&scp=2&sq=dr.%20oz&st=cse

This NY Times article goes on to explain how the RealAge scheme operates:

People come to the site, then provide an e-mail address to take [the RealAge test]. They are asked throughout the test if they would like a free RealAge membership. If people answer yes to any of the prompts, they become RealAge members, and their test results go into a marketing database.

RealAge allows drug companies to send e-mail messages based on those test results. It acts as a clearinghouse for drug companies, including Pfizer, Novartis and GlaxoSmithKline, allowing them to use almost any combination of answers from the test to find people to market to, including whether someone is taking antidepressants, how sexually active they are and even if their marriage is happy.

RealAge sends the selected recipients a series of e-mail messages about a condition they might have, usually sponsored by a drug company that sells a medication for that condition.

The RealAge ads seen all over the internet do not openly disclose that taking the RealAge test gets you signed up to be solicited by Big Pharma for medication advertisements. Dr. Oz's continued promotion of this service has exposed tens of millions of health consumers to this *deceptive marketing* front for Big Pharma.

How much has Dr. Oz earned from his affiliation with RealAge? He isn't saying.

Front man for Big Pharma?

In my view, Dr. Mehmet Oz. is a front man for Big Pharma and the vaccine industry. He's pushing vaccines for his own personal financial gain while championing one of the largest internet Big Pharma marketing scams yet concocted.

Dr. Oz. stands to profit millions of dollars from helping creating demand for vaccines, and yet he does not disclose to his audience this huge, blatant conflict of interest. Sadly, by catapulting his career from her own show, Oprah has inadvertently unleashed a vaccine pusher onto the general public and given him influence over millions of people who may now be corralled into services like RealAge that seek to sell more drugs to unsuspecting consumers.

I respect Oprah. She's an amazing achiever. But I don't respect all the wannabe celebrity leeches who use her to launch their own careers and then exploit their newfound popularity for financial gain at the expense of the public.

Shame on Dr. Oz. for his financial conflicts of interest and his strong affiliation with the deadly pharmaceutical industry. Through his actions, Dr. Oz. has aligned himself with precisely the evil corporations that are destroying health in America today. Does the man have no shame?

He may not have any shame, but he does have 150,000 stock options that could be worth millions in the years ahead.

LE SOIR

Les gynécologues obstétriciens soupçonnés de partialité

LE Soir, 13 novembre 2009, 16:47
http://www.lesoir.be:80/actualite/sciences_sante/2009-11-13/vaccin-a-h1n1-les-gynecologues-obstetriciens-soupconnes-de-partialite-737891.shtmles (deletede)

L'avocat Georges-Henri Beauthier – qui a assigné l'Etat belge en référé au nom de quatre femmes enceintes – soupçonne de partialité le Groupement des gynécologues obstétriciens de langue française de Belgique, en raison du fait que celui-ci est sponsorisé par GlaxoSmithKline, le producteur du vaccin adjuvanté.

Le GGOLFB avait indiqué le 2 novembre qu'il recommandait aux femmes enceintes de se faire vacciner contre le virus A/H1N1.

«L'association, sur son site internet, ne cache absolument pas qu'elle est sponsorisée par Glaxo-SmithKline, le producteur du vaccin adjuvanté», indique Me Beauthier dans la citation adressée au huissier. Le GGOLFB mentionne en effet sur des documents GlaxoSmithKline parmi ses sponsors.

Le GGOLFB n'était pas joignable vendredi après-midi par téléphone.

Les quatre femmes enceintes à l'initiative de la citation demandent à pouvoir bénéficier de vaccins contre le virus A H1N1, ne contenant pas d'adjuvant. Elles estiment être en droit de pouvoir choisir le vaccin qui corresponde le mieux à leur situation.

En France, le Haut Conseil de Santé publique recommande préférentiellement la vaccination des femmes enceintes avec un vaccin sans adjuvant. Au Canada, le gouvernement a commandé des doses de vaccin sans adjuvant destinées aux femmes enceintes. En Suisse, l'agence des médicaments n'a pas avalisé l'usage du vaccin adjuvanté Pandemrix pour les femmes enceintes. L'affaire sera plaidée mercredi matin à Bruxelles.

Le tribunal de première instance de Bruxelles a déclaré irrecevable, lundi, la demande d'un collectif de citoyens de suspendre la campagne de vaccination contre la grippe H1N1. Ce collectif de citoyen a interjeté jeudi appel. L'audience est fixée au 19 novembre. =>

THE FLU CASE

Belgian doctors group that recommended swine flu jab sponsored by GSK

The Flu Case, 13 November 2009, 17:42
https://web.archive.org/web/20100102035211/http://theflucase.com/index.php?option=com_content&view=article&id=1781%3Abelgian-doctors-group-that-recommended-swine-flu-jab-sponsored-by-gsk&catid=1%3Alatest-news&Itemid=64&lang=en

A Belgian lawyer who has helped launch legal action against the government's mass vaccination campaign has accused the Grouping of French-speaking gynaecological obsetricians in Belgian (GGOLFB) of being influenced by their financial links with GlaxoSmithKline when they recommended that pregnant women get the swine flu jab on November 2nd.

GGOLFB says in its own documents that it is sponsored by GSK among other companies.

7 SUR 7

Vaccination: une effroyable imposture?

7 sur 7, 13 Novembre 2009, 21:26
https://www.7sur7.be/home/vaccination-une-effroyable-imposture~a758660f/?referrer=https%3A%2F%2Fwww.google.com%2F

Dans ce montage d'extraits télévisés d'interviews de spécialistes renommés, la campagne de vaccination contre la grippe A/H1N1 est dénoncée comme une vaste manipulation qui risque de mener à une véritable pandémie plus dangereuse que la grippe en elle-même.

À en croire les témoignages, les politiques sont complices des laboratoires pharmaceutiques pour créer un état de panique et une pandémie désastreuse tant pour la santé publique que pour la démocratie... Allergiques des théories du complot s'abstenir.

Stærk lobbyisme bag WHO-beslutning om massevaccination

Information, 16 November 2009
https://www.information.dk/udland/2009/11/staerk-lobbyisme-bag-who-beslutning-massevaccination?lst_cntrb

Flere af WHO's influenzarådgivere er betalt af medicinalindustrien. Dermed var industrien med til at påvirke beslutningen om, at influenza A er en pandemi - og at vaccine er nødvendig. Siden har de samme virksomheder fået vaccineordrer for op mod 55 milliarder kroner.

Den 11. juni 2009 erklærede WHO's generaldirektør, Margaret Chan, svineinfluenza for en pandemi. Det betød en kæmpe økonomisk gevinst for medicinalindustrien. Mange medlemslande - herunder Danmark - har nemlig kontrakter med de store medicinalvirksomheder og er derfor forpligtet til at købe vacciner i tilfælde af en pandemi.

Investeringsbanken JP Morgan vurderer, at medicinalindustrien i år vil modtage vaccineordrer for op imod 55 milliarder kroner. En stor del af den omsætning skyldes WHO's beslutning.

Mange af de tilsyneladende uvildige forskere, som WHO benytter sig af, er imidlertid betalt af de firmaer, der producerer vaccinerne.

De mange dobbeltroller er problematiske, mener professor Tom Jefferson, der er epidemiolog ved Cochrane Center i Rom:

»Det er bekymrende, at mange af medlemmerne i WHO's komitéer, underskriver sig selv med andre titler, selv om de rent faktisk repræsenterer medicinalindustrien,« siger han til Information.

En af eksperterne i WHO's særlige H1N1-rådgivningsgruppe, Dr. Albert Ostenhaus, er netop blevet et punkt på den hollandske regerings dagsorden. Regeringen har indkaldte til et krisemøde, fordi det i en artikel i Science er kommet frem, at Albert Ostenhaus har økonomiske interesser i flere medicinalvirksomheder.

Samtidig er Dr. Albert Ostenhaus i Holland kendt som 'Dr. Flu' fordi han promoverer vaccine som løsningen på epidemier.

Dr. Frederick Hayden er ekstern ekspert i WHO's råd SAGE (Strategiz Advisory Group of Experts), som rådgiver WHO om vacciner. Han fremstår i de officielle papirer som influenza-forskningskoordinator fra den anonymt-lydende 'The Welcome Trust' i London.

Men i en Google-søgning fremgår det, at Dr. Hayden har mange andre arbejdsgivere. Han er bl.a. 'betalt rådgiver' for medicinalvirksomhederne Roche, RW Johnson, SmithKline Beecham og Glaxo Wellcome.

Dr. Arnold Monto, der også fremstår som inviteret ekspert på SAGE's medlemsliste er betalt konsulent i virksomhederne MedImmune, der producerer inhalerbar influenzavaccine, Glaxo Wellcome og ViroPharma. På SAGE's liste står han kun opført som leder af en afdeling på University of Michigan.

Udover eksperterne i SAGE sidder også flere af de store vaccineproducenter som GlaxoSmithKline, Novartis og Baxter med som 'observatører' når SAGE holder møde i WHO:

»Det er en herrens samling mennesker,« siger speciallæge i samfundsmedicin, og tidligere ansat på Aarhus Universitet Mauri Johansson.

»Der er jo flere medicinalindustrifolk i lokalet, end der er beslutningstagere. Den viser alt om den sammenblanding, der foregår. De kaldes 'observatører'. Men man kan undre sig over, at de overhovedet skal være til stede,« siger Mauri Johansson.

Han mener, at det gør det svært at gennemskue, hvad der er op og ned:

»Der sidder en dyne af medicinallobby i WHO, og det har kørt sådan længe. Det er svært at gennemskue, hvad der er industriens interesse, og hvad der er saglig information, siger han.

I referatet fra et SAGE-møde, som blev afholdt den 7. juli, står der blandt andet, at: »Det vil formentlig være nødvendigt, at give to doser vaccine for at sikre beskyttelse,« selv om flere forskere har påpeget, at en enkelt vaccine bør være nok. I mødereferatet anbefaler man også, at alle ansatte i sundhedssektoren samt alle gravide skal vaccineres. Desuden noterer man, at der er brug for »en bedre forståelse af den globale vaccineefterspørgsel« og medlemslandene »opfordres til at overveje brug af vaccine som en del af deres pandemiberedskab.«

Mystiske anbefalinger

Også Tom Jefferson fra Cochrane er stødt på mystiske anbefalinger fra WHO:

»I WHO's seneste anbefalinger om kontrol af pandemisk influenza er masker og hyppig vask af hænderne nævnt to gange. Vacciner og antiviraler er derimod nævnt 24 og 18 gange. Hvorfor vil et internationalt folkesundhedsorgan lægge vægt på en langt dyrere indgreb som vacciner og medicin, når det ikke er bevist, at de virker?« siger han og understreger, at håndvask er det eneste, der med sikkerhed har en effekt.

Wolf Dieter Ludwig, der er leder af lægemiddelkommissionen i den tyske lægeforening er ikke i tvivl om, hvad der er sket:

»Myndighederne er faldet for en kampagne fra medicinalvirksomhederne, som går ud på at tjene penge på en ikke-eksisterende trussel,« siger han til Der Spiegel.

Ifølge Tom Jefferson bør resultatet være, at WHO-komitéen splittes op:

»Rådgiverne skal adskilles fra WHO-beslutningstagere og fra dem, der evaluerer WHO-anbefalinger. Det skal være to adskilte processer. Og så må vi sikre, at ingen kan slippe af sted med at undlade offentliggørelse af deres interessekonflikter,«siger han.

Noget at bidrage med

Talsmand i WHO, Gregory Härtl, mener, at det er helt naturligt, at medicinalindustrien deltager i WHO's møder.

»Alle har noget at bidrage med i denne proces - industrien og ngo'er og professionelle deltagere - så vi kan samle alle informationer. De kan ikke stemme, de har ingen indflydelse på udfaldet, og de kan kun udtale sig, når de bliver spurgt. Når vi skal lave vaccineanbefalinger, så har vi brug for viden om, hvad der skal til for at producere en vaccine. Det er kun producenten, der har den viden.«

- Frederick Hayden og Alfred Monto deltog i mødet den 7. juli som eksperter fra et universitet, men de er begge betalt af medicinalindustrien. Oplysninger om deres finansielle tilhørsforhold er bare ikke offentligt tilgængelige i WHO-regi. Hvorfor ikke?

»Alle eksperter skal skrive under på erklæring om deres interessekonflikter, så vi er klar over deres baggrund. Men igen, Frederick Hayden er den bedste influenzavirolog i verden, så hvis man vil vide, hvordan en influenza opfører sig, så spørger man Fred Hayden. Uanset hvad han ellers laver. Det er derfor, at der er forskel på observatører og deltagere.«

- Men hvorfor deles de finansielle oplysninger ikke med offentligheden?

»Jeg er ikke sikker på, hvorfor vi ikke offentliggør det... det kan jeg ikke svare dig på«.

- Hvis forskere fra WHO advarer millioner af mennesker om en livsfarlig pandemi og anbefaler en vaccine, som det så viser sig, at han har økonomiske interesser i. Vil det så få nogle konsekvenser i WHO-regi?

»Det ved jeg ikke... WHO har et system, der garanterer uafhængighed. Vi er opmærksomme på, at vi ikke lader noget eller nogen få indflydelse på os«.

- Vil WHO fortsætte med ikke at offentliggøre medicinske eksperters finansielle interesser?

»Det vil jeg ikke udtale mig om... det er muligt, at vi vil se på et kodeks for offentliggørelse af finansielle oplysninger, men jeg kan ikke love noget.«

Intensified lobbying for WHO decision on mass vaccination

Information, 16 November 2009
https://www.information.dk/udland/2009/11/staerk-lobbyisme-bag-who-beslutning-massevaccination?lst_cntrb

Several of the WHO's influenza advisors are paid by the pharmaceutical industry. The industry thus helped to influence the decision that influenza A is a pandemic – and that a vaccine is necessary. Since then, the same companies have received vaccine orders worth up to DKK 55 billion.

On 11 June 2009, WHO Director-General Margaret Chan declared swine flu a pandemic. This meant a huge financial gain for the pharmaceutical industry. Many member states - including Denmark - have contracts with the large pharmaceutical companies and are therefore obliged to buy vaccines in the event of a pandemic.

The investment bank JP Morgan estimates that the pharmaceutical industry will receive vaccine orders worth up to DKK 55 billion this year. A large part of that turnover is due to the WHO's decision.

However, many of the apparently impartial researchers that the WHO uses are paid by the companies that produce the vaccines. The many dual roles are problematic, believes Professor T**om Jefferson**, an epidemiologist at the Cochrane Center in Rome: "It is worrying that many of the members of WHO's committees sign themselves with other titles, even though they actually represent the pharmaceutical industry," he says to Information.

One of the experts in the WHO special H1N1 advisory group, Dr. **Albert Ostenhaus**, has just become an item on the Dutch government's agenda. The government has called a crisis meeting because it has emerged in an article in Science that Albert Ostenhaus has financial interests in several pharmaceutical companies. At the same time, Dr. Albert Ostenhaus in Holland known as 'Dr. Flu' because he promotes vaccine as the solution to epidemics.

Dr. **Frederick Hayden** is an external expert in WHO's council SAGE (Strategiz Advisory Group of Experts), which advises WHO on vaccines. He appears in the official papers as an influenza research coordinator from the anonymous-sounding 'The Welcome Trust' in London. But in a Google search it appears that Dr. Hayden has many other employers. He is, among other things, 'paid consultant' to pharmaceutical companies Roche, RW Johnson, SmithKline Beecham and Glaxo Wellcome.

Dr. **Arnold Monto**, who also appears as an invited expert on SAGE's member list, is a paid consultant for the companies MedImmune, which produces inhalable influenza vaccine, Glaxo Wellcome and ViroPharma. On SAGE's list, he is listed only as head of a department at the University of Michigan.

In addition to the experts in SAGE, several of the major vaccine manufacturers such as GlaxoSmith Kline, Novartis and Baxter also sit as 'observers' when SAGE holds a meeting at the WHO:

"It's a great collection of people," says specialist in community medicine, and former employee at Aarhus University Mauri Johansson. "After all, there are more pharmaceutical industry people in the room than there are decision-makers. It shows everything about the commingling that is going on. They are called 'observers'. But one can wonder that they have to be present at all,' says Mauri Johansson.

He believes that this makes it difficult to see what is up and down:

"There is a blanket of medicine lobby in the WHO, and it has been going on like this for a long time. It is difficult to discern what is in the industry's interest and what is factual information, he says.

In the minutes of a SAGE meeting, which was held on 7 July, it is stated, among other things, that: "It will probably be necessary to give two doses of vaccine to ensure protection," although several researchers have pointed out that a single vaccine should be enough. In the minutes of the meeting, it is also recommended that all employees in the health sector and all pregnant women should be vaccinated. In addition, it is noted that there is a need for "a better understanding of the global vaccine demand" and the member states "are encouraged to consider the use of vaccine as part of their pandemic preparedness."

Mysterious recommendations

Tom Jefferson from Cochrane has also encountered mysterious recommendations from the WHO:
"In the WHO's latest recommendations on the control of pandemic influenza, masks and frequent hand washing are mentioned twice. Vaccines and antivirals, on the other hand, are mentioned 24 and 18 times. Why would an international public health organization emphasize a much more expensive intervention such as vaccines and medicine when it has not been proven that they work?' he says and emphasizes that handwashing is the only thing that is certain to have an effect.

Wolf Dieter Ludwig, who is head of the pharmaceutical commission of the German Medical Association, has no doubts about what has happened: "The authorities have fallen for a campaign by the pharmaceutical companies, which aims to make money from a non-existent threat," he says to Der Spiegel.
According to **Tom Jefferson**, the result should be that the WHO committee splits up:
"The advisers must be separated from WHO decision-makers and from those who evaluate WHO recommendations. It must be two separate processes. And then we must ensure that no one can get away with not disclosing their conflicts of interest,' he says.

Something to contribute

Spokesman for the WHO, **Gregory Härtl**, believes that it is quite natural that the pharmaceutical industry participates in the WHO's meetings. "Everyone has something to contribute to this process - the industry and NGOs and professional participants - so we can gather all the information. They cannot vote, they have no influence on the outcome, and they can only speak when asked. When we have to make vaccine recommendations, we need knowledge about what is needed to produce a vaccine. Only the manufacturer has that knowledge.'
- Frederick Hayden and Alfred Monto attended the July 7 meeting as experts from a university, but they are both paid by the pharmaceutical industry. Information about their financial affiliations is just not publicly available under WHO auspices. Why not?
"All experts must sign a declaration of their conflicts of interest, so that we are aware of their background. But then again, Frederick Hayden is the best influenza virologist in the world, so if you want to know how a flu behaves, you ask Fred Hayden. Regardless of what else he does. That is why there is a difference between observers and participants.'

- But why is the financial information not shared with the public?
"I'm not sure why we don't publish it... I can't answer that for you."
- If researchers from the WHO warn millions of people about a life-threatening pandemic and recommend a vaccine, in which it turns out that he has a financial interest. Will this have any consequences under the auspices of the WHO?
"I don't know... WHO has a system that guarantees independence. We are aware that we do not let anything or anyone influence us'.
- Will the WHO continue not to disclose the financial interests of medical experts?
"I will not comment on that... it is possible that we will look at a code for the publication of financial information, but I cannot promise anything."

Усиленное лоббирование решения ВОЗ о массовой вакцинации

Information, 16 ноября 2009
https://www.information.dk/udland/2009/11/staerk-lobbyisme-bag-who-beslutning-massevaccination?lst_cntrb

Фармацевтическая промышленность оплачивает работу нескольких консультантов ВОЗ по гриппу. Таким образом, отрасль помогла повлиять на решение о том, что грипп А является пандемией и что вакцина необходима. С тех пор те же компании получили заказы на вакцины на сумму до 55 миллиардов датских крон.

11 июня 2009 г. Генеральный директор ВОЗ Маргарет Чен объявила свиной грипп пандемией. Это означало огромную финансовую выгоду для фармацевтической промышленности. Многие государства-члены, в том числе Дания, имеют контракты с крупными фармацевтическими компаниями и поэтому обязаны закупать вакцины в случае пандемии.

По оценкам инвестиционного банка JP Morgan, в этом году фармацевтическая промышленность получит заказы на вакцины на сумму до 55 миллиардов датских крон. Большая часть этого оборота связана с решением ВОЗ. –

Однако многие внешне беспристрастные исследователи, которых использует ВОЗ, получают деньги от компаний, производящих вакцины.

Многие двойные роли проблематичны, считает профессор **Том Джефферсон**, эпидемиолог из Кокрановского центра в Риме: «Вызывает беспокойство тот факт, что многие члены комитетов ВОЗ подписывают себя другими титулами, хотя на самом деле они представляют фармацевтическую промышленность», – сказал он журналу «Информация».

Один из экспертов специальной консультативной группы ВОЗ по гриппу H1N1. ***Альберт Остенхаус*** только что стал пунктом повестки дня правительства Нидерландов. Правительство созвало кризисное совещание, потому что в статье в журнале Science выяснилось, что Альберт Остенхаус имеет финансовые интересы в нескольких фармацевтических компаниях. В то же время Др. Альберт Остенхаус в Голландии, известный как «Dr. Грипп», потому что он пропагандирует вакцину как средство от эпидемий.

Др. Фредерик Хейден является внешним экспертом в совете ВОЗ SAGE (Strategy Advisory Group of Experts - Консультативная группа экспертов по стратегии), который консультирует ВОЗ по вакцинам. Он фигурирует в официальных газетах как координатор исследований гриппа из лондонской анонимно звучащей «The Welcome Trust». Но в поиске Google оказывается, что Dr. Хайдена много других работодателей. Он, между прочим, «оплачиваемый консультант» фармацевтических компаний Roche, RW Johnson, SmithKline Beecham и Glaxo Wellcome.

Др. Арнольд Монто, который также фигурирует в качестве приглашенного эксперта в списке членов SAGE, является оплачиваемым консультантом компаний MedImmune, производящих ингаляционную вакцину против гриппа, Glaxo Wellcome и ViroPharma. В списке SAGE он указан только как глава отдела Мичиганского университета.

Помимо экспертов SAGE, несколько крупных производителей вакцин, таких как GlaxoSmithKline, Novartis и Baxter, также присутствуют в качестве «наблюдателей», когда SAGE проводит встречу в ВОЗ:

«Это большое собрание людей», – говорит специалист по общественной медицине и бывший сотрудник Орхусского университета Маури Йоханссон. «В конце концов, в зале больше представителей фармацевтической промышленности, чем лиц, принимающих решения. Он показывает все о смешивании, которое происходит. Их называют «наблюдателями». Но можно удивиться, что они вообще должны присутствовать», – говорит Маури Йоханссон.

Он считает, что из-за этого трудно увидеть, что вверх, а что вниз: «В ВОЗ существует лобби медицинского лобби, и это продолжается уже долгое время. По его словам, трудно отличить, что в интересах отрасли, а что является фактической информацией.

В протоколе заседания СКГЭ, которое состоялось 7 июля, говорится, среди прочего, что: «Вероятно, будет необходимо ввести две дозы вакцины для обеспечения защиты», хотя некоторые исследователи указывали, что одной вакцины должно быть достаточно. В протоколе собрания также рекомендовано вакцинировать всех работников сферы здравоохранения и всех беременных женщин. Кроме того, отмечается, что необходимо «лучше понять глобальный спрос на вакцины», и государствам-членам «рекомендуется рассмотреть возможность использования вакцины как часть своей готовности к пандемии».

Таинственные рекомендации

Том Джефферсон из Cochrane также столкнулся с загадочными рекомендациями ВОЗ:
«В последних рекомендациях ВОЗ по борьбе с пандемическим гриппом маски и частое мытье рук упоминаются дважды. С другой стороны, вакцины и противовирусные препараты упоминаются 24 и 18 раз. Зачем международной организации общественного здравоохранения подчеркивать гораздо более дорогостоящее вмешательство, такое как вакцины и лекарства, если не доказано, что они работают?», – говорит он и подчеркивает, что мытье рук – это единственное, что обязательно даст эффект.

Вольф Дитер Людвиг, глава фармацевтической комиссии Немецкой медицинской ассоциации, не сомневается в случившемся: «Власти попались на удочку фармацевтических компаний, цель которой – заработать на несуществующей угрозе», – сказал он Der Spiegel.

По словам **Тома Джефферсона**, результатом должно стать разделение комитета ВОЗ:
«Советники должны быть отделены от лиц, принимающих решения ВОЗ, и от тех, кто оценивает рекомендации ВОЗ. Это должны быть два отдельных процесса. И тогда мы должны гарантировать, что никто не сможет уйти от ответственности, не раскрывая свои конфликты интересов», – говорит он.

Что-то, чтобы внести свой вклад

Представитель ВОЗ **Грегори Хартл** считает вполне естественным, что представители фармацевтической промышленности участвуют в заседаниях ВОЗ.

"Все есть что внести в этот процесс - промышленность, НПО и профессиональные участники – поэтому мы можем собрать всю информацию. Они не могут голосовать, не имеют никакого влияния на результат и могут говорить только тогда, когда их об этом просят. Когда нам нужно давать рекомендации по вакцинам, нам нужны знания о том, что необходимо для производства вакцины. Этими знаниями обладает только производитель».

- Фредерик Хейден и **Альфред Монто** присутствовали на встрече 7 июля в качестве экспертов из университета, но им обоим платит фармацевтическая промышленность. Информация об их финансовой принадлежности просто недоступна для общественности под эгидой ВОЗ. Почему бы и нет?

«Все эксперты должны подписать заявление о конфликте интересов, чтобы мы знали об их прошлом. Но опять же, Фредерик Хейден – лучший вирусолог гриппа в мире, поэтому, если вы хотите узнать, как ведет себя грипп, спросите у Фредерика Хейдена. Независимо от того, что он еще делает. Вот почему существует разница между наблюдателями и участниками».

- Но почему финансовая информация не доводится до общественности?

«Я не знаю, почему мы не публикуем это... Я не могу вам ответить».

- Если исследователи из ВОЗ предупредят миллионы людей об опасной для жизни пандемии и порекомендуют вакцину, в чем выяснится, что у него есть финансовый интерес, это будет иметь какие-то последствия под эгидой ВОЗ?

«Я не знаю… У ВОЗ есть система, которая гарантирует независимость. Мы осознаем, что не позволяем ничему и никому влиять на нас».

- ВОЗ и дальше будет не раскрывать финансовые интересы медицинских экспертов?

"Я не буду это комментировать... возможно, мы рассмотрим кодекс публикации финансовой информации, но я ничего не обещаю".

Zu NDR.DE NDR

"Profiteure der Angst - das Geschäft mit der Schweinegrippe"

NDR, 20 November 2009, 12:29 Uhr
Sendetermin: Montag, 23. November, 23.00 Uhr, NDR Fernsehen
https://www.ndr.de/der_ndr/presse/mitteilungen/pressemeldungndr4958.html

Die derzeitige Grippewelle ängstigt die Menschen weltweit. Das Virus vom Subtyp A/H1N1 – besser bekannt als Schweinegrippe – verbreitet sich rasant. Das NDR Fernsehen ändert sein Programm und zeigt am Montag, 23. November, um 23.00 Uhr die Dokumentation "Profiteure der Angst – das Geschäft mit der Schweinegrippe".

Im Juni verschärfte die Weltgesundheitsorganisation (WHO) ihre Warnung vor einer Pandemie und rief die höchste Alarmstufe aus. Seitdem versuchen die Gesundheitsbehörden in allen Ländern der Ausbreitung Herr zu werden. Hunderte von Millionen Euro werden für Medikamente und Impfstoffe bereitgestellt. So rasch und ungeprüft wurden Steuergelder wohl noch nie ausgegeben wie im Kampf gegen das neue Grippevirus.

Hat uns eine Massenhysterie erfasst oder ist die neue Grippe tatsächlich eine tödliche Bedrohung? In jedem Fall sind handfeste Interessen im Spiel. Immer mehr Wissenschaftler kritisieren das Vorgehen der Behörden. Jutta Pinzler hat für die NDR Dokumentation "Profiteure der Angst - das Geschäft mit der Schweinegrippe" mit Experten in Deutschland, Großbritannien, Frankreich und der Schweiz gesprochen und gibt einen Überblick über die Vorbereitungen im Kampf gegen das scheinbar unkontrollierbare Virus.

Бизнес на страхе. Свиной грипп (Profiteure der Angst)

Художественный документальный фильм, Arte Doku, 23 ноября 2009
http://www.marchenko.de/profiteure_der_angst_arte_2009

Введение

Здравствуйте, дамы и господа, такое не нравится гражданам, которые живут в современной демократии. Правительство Германии получает не ту вакцину от свиного гриппа, о которой договаривалось. А именно без дополнительного компонента, который должен усиливать действие вакцины. Это средство содержит пандемрикс. Также Франция заказала много вакцины. Без проблем, всё протестировано - утверждает немецкий лицензирующий орган. Вакцинирует своих сотрудников, но тоже без добавки. И в США граждане получают уже испытанное средство без добавки.

Это может заставить задуматься. Канцлер и некоторые министры уже объяснили, что и они использовали бы проверенное средство. Но уже поздно и граждане, несомненно, ещё больше обеспокоены. Ещё и потому, что врачи в целом не советуют вакцинироваться. Так как риски вакцины выше, чем её польза. И сам свиной грипп оказался более безобидным, чем считалось первоначально. Тем не менее Франция заказала 100 мил. доз. В два раза больше, чем Германия.

Теперь массовую вакцинацию будут помогать проводить студенты-медики, студенты-медсестры и врачи на пенсии. Но возникает вопрос, понадобится ли это во Франции. Так как растёт сомнение. Комиссия по медицинским препаратам немецкого объединения врачей считает, что органы здравоохранения повелись на кампанию файрма индустрии. Если вы посмотрите наш фильм, то, вероятно, присоединитесь к этому мнению.

И возможно у вас возникнут вопросы или вы захотите присоединиться к обсуждению. Это можно делать как во время фильма, так и после с автором и врачом Ютой Пинцлер в нашем блоге. ... Итак, бизнес на страхе людей. Бизнес на свином гриппе.

Реакция на вирус

Это просто компания по созданию паники. Это обычный грипп, как и все остальные гриппы. Здесь идёт речь о зарабатывании денег. Я категорически против.

Никто не может сказать мне сегодня, какие побочные эффекты я унаследую, когда сделаю прививку. Страх перед этим страшнее, чем сам грипп.

Я думаю, что фармацевтические компании хотят немного нажиться.

...

Почему ВОЗ вообще объявила пандемию? Была это мера предосторожности или создание ненужной паники? Критики неоднократно указывали организации на слишком близкую связь с фармацевтической промышленностью. Экономические интересы промышленности оказывают влияние на ВОЗ.

Связь с фармацевтикой

Есть ряд людей в ВОЗ, которые работали в фармацевтической промышленности и которые принесли с собой этот образ мышления. А именно таким образом, что решения ВОЗ были удобными для фармацевтической индустрии.

Уже при птичьем гриппе я заметил, что в ВОЗ был ответственный за эпидимеологичускую безопасность. С ним я поговорил в конце года и он не смог назвать причины созданного страха перед птичьим гриппом. Потом я узнал, что он ушёл работать в фарма концерн. Видимо в ВОЗ и фарма индустрии есть карьерные пути, которые пересекаются. Такого не должно быть, конечно же. На заседаниях ВОЗ всегда есть присутствующие из фарма концернов, это не серет.

Так были даны рекомендации при свином гриппе. Norbert Hehme, Jennifer Herz, Stephen Gardner, Comella Kutzer Вероятно они приглашены как наблюдатели эксперты. Фармацевтический производитель GlaxoSmithKline также нанимает экспертов, которые идут работать в ВОЗ или из неё. Близость к ВОЗ может быть большим преимуществом, но об этом не говорят.

Итак, чтобы в конце концов ответить на вопросы, представители компании могут сказать о наличии вакцины или мощностях. Советники не оказывают никакого влияния и не играют никакой роли. Отвечать на вопросы и не оказывать влияния? Ни представители фармацевтики, ни Доминик Ле Гро не видят никакой связи. Он не может понять критику в сторону ВОЗ.

Мы работаем с фармацевтической промышленностью в том смысле, что они производят вакцину. С другой стороны, фарма промышленность не участвует в конференциях и общественных совещаниях. Они не влияют и не имеют права решать. Если вспыхивает инфекционное заболевание, которое лечат препаратом X и если это единственный эффективный препарат, и если этот препарат делает компания Y, значит она больше его продаст. Перед тем, как критизировать фарму за то, что она зарабатывает на заболевании, нужно вообще радоваться, что препарат есть на рынке. Фармаконцерн Rochee - это один из таких Иксов. Производит этот препарат тамифлю против свиного гриппа. Для компании вирус очень желанный. Очевидно, тамифлю занимал место на складах. Но благодаря пандемии быстро продаётся теперь по всему миру. Только в первой половине 2009 Roche смогла увеличить прибыль от тамифлю на 203% до 647 мил. Что сделало её одной из самых успешных компаний в индексе Доу-Джонса. Лондонский аналитик Мартин Бруннингер отмечает, что фармацевтическая промышленность в целом имеет проблемы. Доходы от свиного гриппа сделали долгожданную инъекцию денег для всех фарма фирм.

Это произошло в интересной момент времени, потому что уже много лет назад начал выходить срок патентов. Истечение срока патентов крупных продуктов сильно снижают доходы. Новых разработок становится все меньше и меньше. Это означает, что статус фарма индустрии скорее сложный. Благодаря пандемии, благодаря таким крупным заказам правительств они смогли получить краткосрочную выгоду.

Даже краткосрочная выгода в размере миллиардов евро. Без пандемии никакая компания не получила бы этого. Тот факт, что фарма фирмы всё больше денег инвестрируют в маркетинг, а не новые разработки, становится проблемой.

К началу 2000 года фармацевтическая промышленность переживала тяжелые времена. Не было новых инновационных продуктов, и вставал вопрос, как сохранить высокую рентабельность. Поэтому наши специалисты в фармацевтической отрасли стали значительно развивать сектор вакцин. Благодаря изобретению эпидемии и пандемии, чтобы увеличить продажи вакцин. Первое, что они попробовали, это часто цитируемый птичий грипп. И я напомню, что эксперты, которые кричали о свином гриппе, были теми же, кто кричал о птичьем гриппе.

Однажды Roche получил огромную прибыль с тамифлю. Птичий грипп принес компании рекордные продажи, выручка превысила 550 миллионов евро. 96 стран закупили запасы в то время. Правительство США закупило тамифлю примерно за 48 миллионов евро – прибыльный бизнес для министра обороны Дональда Рамсфельда, потому что он был в то же время акционером и председателем наблюдательного совета американской компании, которая разработала тамифлю и до сих пор владеет патентом на препарат. Даже в то время работы министром Рамсфельд держал долю в компании. Оценочная стоимость не менее четырех миллионов евро. Конфликт интересов он отрицал.

По всему миру можно найти примеры взаимоотношений между фармацевтической промышленностью и политикой. И во Франции министр здравоохранения Розелин Бачелот до своей карьеры политика работала более десяти лет в фармацевтической промышленности, в том числе как PR-менеджер крупной корпорации. В том числе в частично бюджетном Institut Pasteur есть противоречия. Директор Элис Дотри является одновременно консультантом фармацевтической ассоциации. Ни она, ни сотрудники института не были готовы дать интервью. По мнению критиков, это не единственные примеры сплетения между фармацевтической промышленностью и политикой здравоохранения.

Бывший президент национального института профилактики и санитарного просвещения, очень быстро устроился в ассоциации фармацевтической промышленности. Значит в наивысшей инстанции тот, кто решает вопросы здравоохранения и должен работать в интересах общественности, продвигает интересы фарма индустрии. Такое должно быть запрещено.

Система непрозрачна. Невозможно проследить, кто оказывает влияние и на какие решения.

Лобби

Профессор Герд Глеске - экономист здравоохранения из Бремена в течение многих лет критикует непостижимую сплетённость фарма индстрии, правительства и науки. Конечно, мы имеем дело с сильным лоббированием в этой системе. Либбрование оказывает влияние и на науку, что приводит к конфликту интересов. Например, мы видели, как известный учёный в Великобритании сделал доклад о средстве против гриппа, которое выгодно определенной фармацевтической компании. Так что здесь связь очевидна.

В Англии свиной грипп свирепствует больше всего. По крайней мере, здесь введены самые строгие меры против гриппа. По телефону горячей линии любой желающий может запастись лекарствами. Правительство закупило противогриппозных препаратов для 80% населения. Кроме того, были куплены вакцины на сумму около 180 миллионов евро.

Ректор колледжа Сэр Андерсон консультирует правительство по вопросам борьбы с вирусом. Он публично пропагандировал использование противогриппозных препаратов. Британские журналисты выяснили, что медик был в то же время в списке зарплатной ведомости. С ежегодным доходом 116 тыс евро фарма концерна GlaxoSmithKline, который заработал миллиарды на вакцине от гриппа. Министерство и фармацевтические компании отказываются признавать конфликт интересов. Сэр Андерсон утверждает, что не принимал прямого участия в решениях о вакцине.

Безусловно это не единственный случай. Я могу вам назвать эти случаи в Германии. Во всех сферах здравоохранения вы найдите экспертов, которые продвигают свои интересы.

В Германии фармацевтическое лобби особенно сильно. Цены на запатентованные препараты компаниям разрешено устанавливать самим. Здесь не ведут переговоры, как в других европейских странах. В Германии медицинские страховые компании должны оплачивать лекарства не зависимо от их цены. Все попытки изменить это со стороны политики не удались.

Может лобби фармацевтической промышленности быть сильнее, чем забота о защите населения? Очевидно финансирование индустрии имеет большее значение, чем здесь охрана здоровья. Организация "прозрачная Германия" годами обвиняет коррупционные и мошеннические схемы в системе здравоохранения. Медицинские исследования фальсифицируются, повышенные риски препаратов скрываются. Здесь отсутствует политическое регулирование.

Население всегда думает, что существуют контролирующие органы в министерствах и государственных комиссиях. Однако, из-за большого конфликта интересов между вовлеченными людьми и производители, этот контроль практически полностью отсутствует.

Оганизация "прозрачная Германия" также критически относиться к комиссии по вакцинации института Роберта Коха. Институт рекомендует, какие прививки применять и какие оплачиваются медицинским страхованием. Члены комиссии - это медицинские работники, чьи проекты частично финансируются фарма промышленностью. Но президент государственного института не видит в этом проблемы. Комиссия по вакцинации создала правила прозрачности. Вы можете получить информацию из интернета о личностях.

И эти правила можно увидеть и в международном контексте.

На сайте института Роберта Коха можно увидеть, какие, на самом деле отношения связывают её членов с фарма промышленностью. Почти у всех медицинские работников имеются связи, которые ведут к конфликту интересов.

Есть очень интересный вариант толкования этих списков. Некоторые говорят, что за ними стоят три, четыре, пять компаний и это уже факт того, что они независимы. Т.е. они не продвигают отдельных производителей. Думаю, что они недооценивают значение лоббизма. Потому, что это принципиальный вопрос. Можно ли брать деньги от фарма индустрии для стороннего финансирования исследований. Я вам могу точно сказать, что просто так деньги не даются без того, чтобы не получить что-то взамен.

Инвестиции в строительство производства вакцины в Дрездене, видимо, оправдали себя. GSK вложила 200 миллионов евро. в строительство завода. GSK компания ожидает годами пандемию гриппа. Два миллиарда евро было потрачено на разработку вакцины против пандемического гриппа. Однажды это должно окупиться. Германия заказывала пока только у GSK. Франция заказала у четырех разных производителей. Больше половины у GSK. Критики утверждают, что вакцина недостаточно протестирована. Доктором Йенсом Воллмер, медицинский директор спокойно относится к предполагаемым рискам вакцины.

Например, при сезонном гриппе, каждый год мы должны получить новый допуск. И этот процесс быстрее для сезонных вакцин. При шаблонной вакцине. У нас есть допуск на шаблонную вакцину. На основе этого допуска мы можем получить также допуск на H1N1. Это не означает, что проверка проходит менее тщательно. Это значит, что многое уже проверено на шаблонной вакцине.

GSK производит вакцину от гриппа на основе куриных яиц. Затем добавляется усилитель эффекта, так называемый адъювант. Эти адъювантны очень противоречивы, поскольку они могут вызывать либо усилить паралич. Поэтому они были запрещены в США. Эксперты в Европе считают, что тесты шаблонной факцины на безопасность были неадекватными. Немецкие и французские критики делают простой расчет.

Если вы при массовой вакцинации в 20 мил. доз имеете 0,1% побочных эффектов, то это 20 тыс. человек, которые там пострадают от вакцины. И если это опасный побочный эффект, то это можно назвать катастрофой.

Представьте, что у вас 1 к тысячи смертей от осложнений и вы вакцинируете 60 миллионов французов, то умрёт 60 тыс. людей. И это касается всех слоёв населения, дети, беременны, молодые люди, такие как вы, совершенно здоровые. Это катастрофа.

С середины августа идёт тестирование новой вакцины. 1200 взрослых и 2000 детей в Германии в течение 2х недель хотят проверить безопасность вакцины. Участники тестов засекречены. Профессора Фрэнк фон Зонненбург в уничерситете Мюнхена возглавляет исследование Германии. Он не принимает критику.

У нас уже есть опыт с сотнями миллионов вакцин и эта вакцина против гриппа ничем не отличается от других вакцин против гриппа. Здесь нет ничего сенсационно нового. Нужно признаться, что есть редкие побочные эффекты. Их невозможно охватить исследованиями.

Даже если профессор фон Зонненбург убеждён в надёжности вакцин, то влияние фарма индустрии и он замечает. Было бы хорошо, иметь деньги на исследования вакцин. Независимо от индустрии, чтобы можно было сделать определенные исследования вакцин. Например, как достичь лучшего покрытия среди населения и тп.

Такое невозможно сейчас сделать? Это сложно, пот. не хватает денег на это и основаная часть вакцины была оплачена индустрией.

В Германии фарма финансирует не только большую часть исследований, но также имеет огромное влияние на законодательство. Врач Вольфганг Водарг, будучи депутатом Бундестага, сам видел, как ассоциация фармацевтической промышленности делает политику. VFA продала уже закон федеральному правительству Германии. Вот такое могущество. Был закон ценового регулирование запатентованных лекарственных средств. И VFA заплатила 100 мил тогда ещё немецких марок, чтобы мы не применяли этот закон. Было заплачено медицинским страховым компаниям. И федеральное правительство приняло участие в этом.

Производители сделали выплаты страховым компаниям и закон регулирования цен никогда не применялся. Цены патентные препараты фирмы устанавливают сами. Использование средства от гриппа тамифлю вызывает много вопросов. Побочные эффекты препарата просто замалчиваются.

...

Завершение

Однако кукловоды пока скрываются. Как в Германии, так и во Франции. Политики вместо того, чтобы управлять, уступают экономическим интересам. И, кажется, капитулируют перед корпоративным влиянием.

Если у государства нет собственных инструментов, отличать ложь от правды, то оно полностью принадлежит этой индустрии. Отличить ложь от правды в этой пандемии трудно друг от друга. Были ли политические решения выгодны населению? Остаётся под вопросом. Индустрия получила уже выгоду.

И если компания по вакцинации будет неудачной, потому что население больше боится прививки чем гриппа, то оставшаяся вакцина, которую мы уже оплатили и которой не доверяем, может быть подарена развивающимся странам. Такие вот мы щедрые, индустриальные страны. Если у вас есть вопросы или вы хотите обсудить, вы можете это сделать в онлайн блоге с автором этого фильма.

Swine flu pandemic is yet another conspiracy
Danish media

Russia Tuday, 25 November 2009
https://www.youtube.com/watch?v=XFLHbXqSEVQ

Danish journalists claim that the World Health Organization and drug companies producing the swine flu vaccine are in partnership, and that the true nature of their relationship is shrouded in mystery.

"What we do know is that the pharmaceutical companies are present at the meetings of WHO expert groups, but what we don't know is what they talk about. And another thing is that scientists who appear to be independent are also hired consultants working for the same pharmaceutical companies who produce the vaccines," says *Louise Voller*, a journalist at the Danish Daily Information newspaper.

Агенты Вливания: Инициаторы всемирной борьбы со свиным гриппом уличены в подозрительных связях

Новые Известия, 25 Ноября 2009

https://web.archive.org/web/20091129002407/http://www.newizv.ru/news/2009-11-25/117889/

Пандемия свиного гриппа, как уже не раз писали «НИ», может оказаться самой грандиозной коррупционной аферой нашего времени. Во всяком случае, огромная коммерческая составляющая в ней уже очевидна. К такому же выводу пришли датские журналисты, изучившие связи экспертов Всемирной организации здравоохранения (ВОЗ) с ведущими мировыми фармацевтическими компаниями, обогатившимися на продаже препаратов против этой болезни. Выяснилось, например, что многие ученые, заседающие в различных комитетах ВОЗ, тщательно скрывают тот факт, что они получают деньги от фирм-гигантов мировой фармакологии.

По данным международного инвестиционного банка JP Morgan, фармацевтическая промышленность мира заработает в этом году на продаже вакцин против коварного вируса A/H1N1 более 7 млрд. евро. Ведущие западные страны заказали в нескольких компаниях дозы, которых должно хватить либо на все население (по этому пути пошла Австралия), либо на треть (Германия и ряд других государств– членов ЕС). Народ чихает и температурит, а заводы по производству пилюль работают в четыре смены, не ощущая всемирного экономического кризиса: заказы громоздятся штабелями, мощностей не хватает. Впервые за долгие годы паника пандемии смела защитные барьеры ЕС. В виде исключения вакцина была допущена для использования без проведения достаточного количества клинических и лабораторных испытаний.

Оправдана ли такая горячка? Все большее число специалистов задаются этим вопросом, сравнивая статистику смертности от вируса свиного гриппа и его «обычных» разновидностей, каждую осень начинающих свое победное шествие по планете. До сих пор, по данным ВОЗ, жертвами A/H1N1 стали 6 тыс. человек, в то время как средняя ежегодная смертность во время эпидемий «традиционных» разновидностей гриппа достигает полумиллиона.

Причина гипертрофированной реакции мира на не столь уж опасный свиной грипп, как считают опрошенные датской газетой Information специалисты, заключается в успешной пиар-кампании, проведенной экспертами ВОЗ. Некоторые из них в прямом смысле состоят на службе у производителей вакцины.

«Вызывает беспокойство, что многие ученые, заседающие в различных комитетах ВОЗ, представляются независимыми экспертами, тщательно скрывая тот факт, что они получают деньги от фармацевтических компаний», – заявил журналистам профессор эпидемиологии Том Джеферссон, работающий в исследовательском центре Cochrane Center в Риме.

ВОЗ объявила свиной грипп пандемией под давлением группы советников этой организации во главе с голландским доктором Альбертом Остенхаусом, получившим прозвище «Доктор флю» (по названию препарата «Тамифлю»), поскольку он вел активную пропаганду в ВОЗ и западных СМИ в пользу массовой вакцинации населения. Сейчас правительство Нидерландов проводит экстренное расследование деятельности этого «доктора Пилюлькина», поскольку стало известно, что он получает зарплату в нескольких компаниях, производящих вакцину против свиного гриппа. Сидят «на двух стульях», подобно Остенхаусу, и многие другие советники ВОЗ, потребовавшие объявления свиного гриппа пандемией. Они не любят афишировать, что являются платными советниками фармацевтических гигантов Roche, RW Johnson, SmithKline и Beecham Glaxo Wellcome, получивших львиную долю заказов на изготовление вакцин. Итогом давления этих экспертов стала резолюция ВОЗ от 7 июля этого года, давшая старт невиданной кампании массовой вакцинации.

«ВОЗ выступает по меньшей мере со странными рекомендациями, – утверждает профессор Том Джеферссон. – Обычные меры гигиены дают куда больший эффект, чем эти малоизученные вакцины, и в то же время ВОЗ упоминает использование масок и тщательное мытье рук как средство борьбы со свиным гриппом всего дважды в своих документах. О вакцинах и других лекарственных препаратах говорится 42 раза!» Д-р Джеферссон и ряд его коллег считают, что платных советников фармацевтических компаний следует удалить из числа лиц, дающих рекомендации ВОЗ, однако сама эта организация не спешит проводить подобную реформу. Спикер ВОЗ Грегори Хэртл, комментируя статью в Information, заметил, что невозможно отказаться от услуг ведущих мировых специалистов лишь на том основании, что они финансово заинтересованы в продвижении той или иной стратегии борьбы с различными заболеваниями.

Надо заметить, что коррумпированность сферы фармакологии уже не первый год стала предметом обсуждения западных СМИ. Несколько лет назад бывший редактор медицинского журнала The New England Journal of Medicine Марчи Энжелл и швед Петер Фрост, бывший вице-директор фармакологической компании Pfizer, в серии статей и книге-исследовании The Whistleblower показали изнутри жизнь «медицинской мафии». По их утверждению, фармакологические компании лишь 11–14 % бюджета тратят на исследования, зато на пиар у них уходит 36% всех средств. Значительная часть денег оседает в карманах врачей, ученых и на счетах различных организаций, работающих в сфере здравоохранения. Доходность фармацевтической отрасли составляет 25%. Больше прибыли приносят лишь торговля оружием и секс-индустрия.

Экспертов ВОЗ, развернувших всемирную борьбу со свиным гриппом, подозревают в коррупции

News.ru, 25 ноября 2009, 09:37
https://www.newsru.com/world/25nov2009/ah1n1afera.html

Пандемия свиного гриппа может оказаться самой грандиозной коррупционной аферой нашего времени. К такому выводу пришли журналисты датской газеты Information, изучившие связи экспертов Всемирной организации здравоохранения (ВОЗ) с ведущими мировыми фармацевтическими компаниями, обогатившимися на продаже препаратов против этой болезни. Выяснилось, например, что многие ученые, заседающие в различных комитетах ВОЗ, тщательно скрывают тот факт, что они получают деньги от фирм-гигантов мировой фармакологии, пишет газета "Новые известия".

Издание отмечает, что на фоне глобального экономического кризиса благодаря панике, охватившей мир в связи с пандемией свиного гриппа, фармацевтические заводы работают в четыре смены, мощностей не хватает.

Между тем на данный момент по официальной статистике, жертвами гриппа A/H1N1 стали 6 тыс. человек, в то время как средняя ежегодная смертность во время эпидемий "традиционных" разновидностей гриппа достигает полумиллиона.

Причина гипертрофированной реакции мира на не столь уж опасный свиной грипп, как считают опрошенные датской газетой специалисты, заключается в успешной пиар-кампании, проведенной экспертами ВОЗ. Некоторые из них в прямом смысле состоят на службе у производителей вакцины.

ВОЗ объявила свиной грипп пандемией под давлением группы советников этой организации во главе с голландским доктором Альбертом Остенхаусом. Сейчас правительство Нидерландов проводит экстренное расследование его деятельности, поскольку стало известно, что он получает зарплату в нескольких компаниях, производящих вакцину против свиного гриппа.

Многие другие советники ВОЗ, потребовавшие объявления свиного гриппа пандемией, также являются платными советниками фармацевтических гигантов Roche, RW Johnson, SmithKline и Beecham Glaxo Wellcome, получивших львиную долю заказов на изготовление вакцин. Итогом давления этих экспертов стала резолюция ВОЗ от 7 июля этого года, давшая старт невиданной кампании массовой вакцинации, отмечает газета.

Между тем спикер ВОЗ Грегори Хэртл, комментируя статью в Information, заметил, что невозможно отказаться от услуг ведущих мировых специалистов лишь на том основании, что они финансово заинтересованы в продвижении той или иной стратегии борьбы с различными заболеваниями.

Новый грипп - свинья, подложенная фармацевтами?

Комсомольская Правда, 25 ноября 2009, 23:47
https://www.kp.ru/daily/24400/576762/

В скандинавских СМИ появилсь сообщения о том, что европейская вакцина против свиного гриппа может принести больше вреда, чем пользы. Уже зафиксированы случаи массовых аллергических реакций на прививку, а также повышение у людей (особенно у детей) температуры до 38-40 градусов после «спасительного укола». Расследование, проведенное датской газетой *Information*, подтверждает подозрения многих экспертов о том, что массовая вакцинация может быть грандиозной аферой, на которой несколько фармацевтических гигантов успели заработать более 7 млрд. евро.

Рекомендации по тотальной вакцинации были приняты под давлением группы специалистов из Всемирной организации здравоохранения (ВОЗ). Но, как оказалось, многие из них тесно связаны с производителями этой вакцины и даже получают "премиальные" от фармацевтических компаний. Власти Нидерландов начали сейчас расследование деятельности Альберта Остенхауса, доктора, наиболее активно выступавшего в ВОЗ за одобрение «тотальной вакцинации».

Между тем, многочисленные исследования документально доказывают, что вакцины против гриппа вообще мало эффективны, и свиной грипп не является исключением. Изучить безопасность новых препаратов оказалось невозможным из-за недостатка информации о них и широкого разброса в стндартизации. На этом фоне можно предположить, что спешно изготовленная панацея от свиного гриппа ничуть не отличается по качеству и действенности от ранее изготовленных вакцин.

Пока от свиного гриппа и его последствий в мире умерло 6 тысяч человек, в то время, как от обычных эпидемий гриппа погибает до полумиллиона людей.

Пандемия свиного гриппа может быть заговором ВОЗ и фармкомпаний

Ведомости, 26 ноября 2009, 14:30
https://www.vedomosti.ru/politics/articles/2009/11/26/pandemiya-svinogo-grippa-mozhet-byt-zagovorom-voz-i-farmkompanij

Консультанты Всемирной организации здравоохранения получали деньги от производителей лекарств, пишут европейские СМИ

В Европе разгорается скандал вокруг свиного гриппа. Датская газета Dagbladet Information сообщила, что консультанты Всемирной организации здравоохранения (ВОЗ) получали деньги от фармацевтических компаний. Газета полагает, что это могло повлиять на решение ВОЗ об объявлении пандемии свиного гриппа. Всемирная истерия по поводу вируса A/H1N1, по оценке аналитиков JPMorgan, позволила фармацевтическим компаниям заработать в этом году более 7 млрд евро.

По сведениям Dagbladet Information, группа консультантов ВОЗ под руководством голландского врача Альберта Остенхауса оказывала услуги и крупнейшим фармконцернам, получая от них за это деньги. В то же время консультанты ВОЗ должны быть независимыми. В статье упоминаются компании Roche, RW Johnson, GlaxoSmithKline, выпускающие вакцины от вируса. Газете также удалось выяснить, что представители концернов часто посещают заседания ВОЗ, однако о чем они там говорят, не известно. Издание также сообщает, что Остенхаус, ратовавший за объявление пандемии свиного гриппа, попал в центр экстренного расследования голландских властей.

По данным ВОЗ, число подтвержденных случаев заболевания вирусом A/H1N1 в мире превысило 500 000, для более чем 6000 человек болезнь стала смертельной. По информации Минздравсоцразвития России, у нас зафиксировано более 11 500 случаев заболевания свиным гриппом. Более 600 человек скончалось.

"Свиной грипп" как способ заработать

Intefax, 26 ноября 2009, 23:29
https://www.interfax.ru/business/111943

Рынок вакцин, традиционно считавшийся неприбыльным и рискованным, сейчас демонстрирует уверенный рост. Этому будет способствовать и эпидемия "свиного гриппа", на вакцинах против этого вируса компании в этом году заработают $11,1 млрд

Москва. 26 ноября. IFX.RU - Болезни и вирусы – явления, безусловно, природного характера. Однако нынешний рынок с легкостью переводит эти вопросы в категорию экономических. Эпидемия гриппа H1N1, также известного как "свиной грипп", не стала исключением. Новый недуг будет способствовать росту рынка вакцин в целом. На вакцинах против него фармкомпании в этом году заработают около $11,1 млрд.

Фармацевтический рынок известен как низко рентабельный и рискованный. Однако сейчас благодаря вакцинам против "свиного" гриппа он демонстрирует уверенный рост.

Не так давно, вакцины считались самым "бедным" сегментом фарминдустрии, пишет Businessweek.com. Сложность и высокая стоимость их производства отпугивали от этого рынка большинство игроков. Исключением стали лишь несколько: швейцарский гигант Novartis, британская GlaxoSmithKline (GSK), французская Sanofi Aventis, американская Merck и Wyeth (сейчас в составе Pfizer).

Однако в последнее время наблюдается возрождение интереса к производству вакцин. "Все больше компаний инвестируют в вакцины с целью диверсификации производства рецептурных препаратов" - говорит Майкл Бойд, и.о. гендиректора Международной федерации фармацевтических производителей и ассоциаций (IFPMA).

При этом вакцины против гриппа H1N1, по крайней мере, в краткосрочной перспективе будут локомотивом роста продаж вакцин в целом.

В целом, рынок рецептурных лекарственных препаратов с нынешних $780 млрд будет расти не слишком быстрыми темпами - на 5% в год. Рынок вакцин при этом, согласно прогнозам экспертов, может расти на 13% ежегодно вплоть до 2012 года.

Пандемия свиного гриппа, безусловно, также будет способствовать росту продаж. Так, продажи вакцин против "свиного гриппа" компании GSK, как ожидается, только в четвертом квартале 2009 года составят $1,7 млрд. Примерно столько же компания может выручить и в первом квартале нового года.

Novartis планирует, что продажи ее вакцины против нового гриппа в четвертом квартале составят $700 млрд. Ну и Sanofi-Aventis прогнозирует, что ее продажи аналогичной вакцины превысят $500 млн.

Однако рынок вакцин против гриппа отличается сезонностью и непредсказуемостью, отмечает глава Novartis Даниэль Вазелла.

По оценкам инвестиционного банка JP Morgan, в этом году фармацевтические компании получат заказы на производство вакцин против нового гриппа на сумму порядка $11,1 млрд. При этом большая часть товарооборота обусловлена рекомендациями Всемирной организации здравоохранения (ВОЗ), сообщает датская газета Information.

Россия в этом плане не исключение. У нас также запущен выпуск вакцин против нового гриппа. Производством занимаются несколько предприятий. Группа компаний "Петровакс" в ноябре начала производство вакцины МоноГриппол Нео. Ранее сообщалось, что вакцина против свиного гриппа помимо "Петровакса" будет производиться на предприятиях "Микроген" в Иркутске и Уфе, а также в Институте сывороток Федерального медико-биологического агентства в Санкт- Петербурге.

Тем не менее, многие продолжают считать, что свиной грипп не более чем выдумка. В этом, согласно опросу SuperJob.ru, убеждены 30% россиян.

По мнению почти каждого третьего участника исследования, новый вирус - это заговор крупнейших фармацевтических компаний, целью которого является получение денег с напуганного населения, в частности, благодаря реализации вакцин.

"Это плод воспалённого воображения", "Свиной грипп - это выдумка фармацевтических компаний, которым необходимо "впихивать" народу свои вакцины"; "Вероятность того, что это очередной способ выманивания у населения денег на лекарства, очень высока", - комментируют россияне.

Не ставит под сомнение существование свиного гриппа 50% россиян. Среди них немало людей, непосредственно столкнувшихся со случаями заболевания. Каждый пятый респондент затруднился с ответом.

ВЕСТИ.RU

"Свиной грипп"
ВОЗ подозревают в сговоре с фармацевтами

Вести.ru, 26 ноября 2009 11:41
https://www.vesti.ru/article/2182317

В России пик эпидемии гриппа и ОРВИ пройден уже в 18 крупных городах, которые раньше лидировали в списках по числу заболевших. Теперь там всё уже в пределах сезонной нормы. А в Европе разгорается крупный скандал: версия о сговоре фармацевтов, о котором заговорили ещё в первые дни распространения по планете "свиного гриппа", похоже, подтверждается. Часть экспертов Всемирной организации здравоохранения, которая и объявила пандемию, получала деньги от фармацевтических концернов.

"Белые горы" на карантине. Прокуратура Амурской области возбудила уголовное дело по факту массового заболевания детей. Следствию предстоит выяснить, почему администрация санатория не отменила заезд, несмотря на запрет главного санитарного врача Приамурья. В результате за 11 дней в санатории заболели 58 школьников. Некоторым из них уже поставлен диагноз – "свиной грипп".

"Я попала сюда с температурой, голова заболела, и я пошла за градусником. Наверное, это грипп, так как температура была высокая, я спала почти все время", – рассказывает Дарья Полевая, одна из заболевших.

В "Белых горах" остается ещё более ста детей. Их смена закончится через несколько дней. В точности диагноза у специалистов сомнений нет. Информация о массовом заболевании стала общедоступной благодаря Роспотребнадзору и СМИ. С претензиями администрация санатория не согласна.

"Это наша контролирующая организация, надо было работать совместно. Санаторий у нас был полностью готов, у нас был масочный режим, запас лекарств, персонал прошел вакцинацию против гриппа", – объясняет Ольга Зарубова, заместитель генерального директора по медицинской части НП "Соку".

Несмотря на серьезные меры предосторожности, все равно произошло массовое заболевание детей. По данным прокурорской проверки, прослеживается цепь халатностей. Дети поступали со справками, но, видимо, уже инфицированные. А в санатории больные и здоровые дети если и разделялись, то ненадолго.

"По сверкам журналов выяснили, что в изоляторе они были вместо семи дней два. В следственный отдел в отношении руководителя учреждения направлены документы о возбуждении уголовного дела", – заявила Алена Козлова, помощник прокурора Райчихинска.

В целом по России ситуация с ОРВИ и опасными вирусами гриппа остаётся контролируемой, а в некоторых регионах заболеваемость даже идёт на спад. Татьяна Голикова, министр здравоохранения и социального развития РФ.

В Европе, тем временем, разразился громкий скандал. Датские журналисты выяснили, что эксперты Всемирной организации здравоохранения получали деньги от фармацевтических гигантов – тех самых, которые из-за возникшей по всему миру паники получили баснословную прибыль от продажи противовирусных препаратов. По некоторым данным, она может составить, как минимум, 7 миллиардов долларов. Новый вирус гриппа породил новый вид аферы, утверждает датская пресса. Ибо именно под давлением таких проплаченных специалистов и была объявлена пандемия гриппа. Группу экспертов ВОЗ возглавляет голландский врач Альберт Остенхаус, прозванный в прессе Доктором Флю.

"Мы точно знаем, что представители фармацевтических компаний – постоянные гости на заседаниях ВОЗ. Кроме того, привлекаемые организацией ученые, которые по идее должны быть независимыми, совмещают работу на ВОЗ с службой в фармацевтических компаниях", – рассказала датская журналистка.

Деятельность Остенхауса теперь расследует специальная комиссия правительства Голландии.

Кстати, британские медики, как сообщает The Daily Telegraph, пришли к выводу, что каждый пятый ребёнок в стране переболел "свиным гриппом" и даже не заметил этого. В большинстве случаев заболевание прошло без осложнений.

Депутат Игорь Баринов требует расследования коррупции в ВОЗ
пандемию «свиного гриппа» врачи могли придумать в сговоре с фармацевтами

URA.ru, 26 ноября 2009, 17:00
https://m.ura.news/news/1052106751

Член комиссии Госдумы РФ по законодательному обеспечению противодействия коррупции Игорь Баринов предложил провести комплексное расследование возможного сговора экспертов Всемирной организации здравоохранения с фармацевтическими кампаниями. Такой сговор мог привести к неадекватной истерии вокруг вируса гриппа A/H1N1, что многократно увеличило спрос на продукцию фармацевтов. Отметим, вчера о возможности такого сговора рассказали европейские СМИ.

«Россия в числе других стран пострадала от истерии вокруг «свиного гриппа», - говорит Баринов. – При этом у нас до сих пор нет четкого понимания, насколько реальна эта угроза. Мы видели аналогичные всплески информационной активности вокруг т.н. «куриного гриппа» и «атипичной пневмонии», однако сейчас об этих заболеваниях не слышно. Нельзя исключать возможности, что речь идет об очередной PR-кампании международных фармацевтических концернов и угроза пандемии нового вируса гриппа скорее виртуальна. А вот потери бюджета и российской экономики абсолютно реальны. Они будут подсчитаны, но уже сейчас понятно, что счет идет на миллиарды».

Игорь Баринов говорит, что готовит обращения в Генпрокуратуру РФ и Минздравсоцразвития с просьбой инициировать официальное расследование возможной коррупции в ВОЗ. «Это должно быть справедливое и независимое расследование, в котором примут участие международные эксперты, в том числе российские. В случае, если факт сговора будет доказан, Россия как субъект международного права может направить иски к ВОЗ или фармацевтическим кампаниям с целью взыскания убытков». По словам депутата, речь идет не только о деньгах, но и о спокойствии населения. «Я много работаю в регионах, и вижу, что люди обеспокоены той истерией, которую развернули вокруг вируса СМИ. Реальность смертей от A/H1N1 не вызывает сомнений, однако масштабы бедствия могут оказаться в разы меньше, чем пытаются представить эксперты и фармацевты», - считает российский депутат.

НОВОСТИ

Ирада Зейналова

Пандемия нового гриппа может оказаться грандиозной мистификацией

1TV.ru, 26 ноября 2009, 21:08
https://www.1tv.ru/news/2009-11-26/155681-pandemiya_novogo_grippa_mozhet_okazatsya_grandioznoy_mistifikatsiey

В мире сейчас разгорается скандал, в центре которого - Всемирная Организация Здравоохранения. В европейской прессе появились публикации о возможном сговоре экспертов ВОЗ с ведущими фармацевтическими компаниями.

Паника вокруг вируса A(H1N1) позволила производителям препаратов получить баснословные прибыли. Журналисты делают смелые предположения, что объявленная ВОЗ пандемия нового гриппа может оказаться грандиозной мистификацией.

Заводы работают денно и нощно, в четыре смены, производя спасительные лекарства. Объем заказов крупнейших фармацевтических фирм – все население Европы, плюс все население Америки, плюс сотни миллионов доз для Азии и Африки. Паника снесла защитные барьеры Евросоюза - в виде исключения, вакцина допущена беспрекословно в европейские страны без проведения достаточных клинических испытаний.

Питер Палезе, эпидемиолог (США): "Назвать вспышку A(H1N1) пандемией – чисто политическое решение. И его могли принять только на совете ВОЗ. Хочу сказать, что это мобилизирует людей в борьбе с новым вирусом. Вакцина производится и ее доставляют в больницы".

Россия панике не поддалась – здесь специалисты не устают повторять: эпидемии нет, обойдемся без паники. В любом случае, мы предпочитаем проверенные средства.

Татьяна Голикова, министр здравоохранения и социального развития РФ: "Мы не проводили ускоренных испытаний, как, скажем, в США. Плюс, смертность от всех видов гриппа не превышает 600 человек".

Объявленная главой Всемирной Организации Здравоохранения Маргарет Чен глобальная гриппозная угроза стала причиной глобальной истерии.

Маргарет Чен, генеральный директор ВОЗ: "На основании данных, имеющихся у экспертов, и по всем научным критериям, достигнут порог пандемии гриппа. Я таким образом приняла решение поднять уровень угрозы с 5-го на 6-й. Пандемия гриппа-2009 в мире началась".

Аптеки от Бомбея до Лондона оказались в кольце желающих купить профилактические средства, рекомендованные врачами. Когда бесплатные европейские клиники захлебнулись в волне желающих сделать прививку или получить заключение, каким гриппом заболели, частные британские врачи ввели новую услугу: экспресс-прием. 125 фунтов.

Сегодня эксперты задают классический вопрос: кому выгодно? Хотя бы потому, что, по данным датской газеты "Информатон", эксперты ВОЗ параллельно работали на крупнейшие фармацевтические корпорации, на момент появления вируса подтянувшие из-за кризиса пояса.

Утверждается даже, что саму пандемию объявили под давлением голландского доктора Альберта Остенхауза, прозванного Доктор Флю за пропаганду всемирной вакцинации от нового гриппа и при этом числящимся платным советником в нескольких компаниях, производящих саму вакцину.

В краткосрочной перспективе всю индустрию выпуска вакцин будет тянуть на буксире спрос на средства от вируса H1N1.

Еще несколько лет назад редактор влиятельного медицинского журнала американец Марчи Энжелл и швед Петер Рост, бывший вице-директор крупнейшего фармахолдинга, утверждали: любые фармацевтические исследования на Западе ведутся на деньги крупных корпораций, на сами исследования тратится менее 14% бюджета и почти 40% - на информационную поддержку новых лекарств. Значительную часть этих денег получают те, кто публично рекомендует как и от чего лечиться. Цитата: "Прибыль в этой отрасли – 25%. Больше – только у торговли оружием и секс-индустрии".

Марлевая повязка и дезинфицирующая жидкость для рук - этот набор стоит в 15 раз дешевле, чем вакцина; не имеют побочных эффектов и, как говорят врачи, могут уберечь от гриппа почти так же надежно. Тем не менее рекомендация ВОЗ о том, что нужна всеобщая вакцинация, упоминается 43 раза, и лишь дважды говорится, что спастись можно и этими подручными средствами.

Влиятельный британский журнал "Ланцет" отвечает тем, кто скептически относится к качеству новой гриппозной вакцины: ее вкололи группе риска. Осложнения у больных сердечно-сосудистыми заболеваниями и выкидыши у беременных женщин сразу после вакцинации – совпадения.

Шри Дасан, инфекционист: "Что бы ни говорили сейчас, эпидемия существует. Она пошла на спад - 50 тысяч человек в этом месяце в Британии по сравнению с 64 тысячами в октябре. Это все равно значительно выше, чем при сезонном гриппе. Вакцинация нужна. Кто и как при этом зарабатывает – другой вопрос".

Михаил Костинов, доктор медицинских наук, профессор, заведующий лабораторией вакцинопрофилактики и иммунотерапии аллергических заболеваний НИИ вакцины и сыворотки имени Мечникова Российской Академии Медицинских Наук: "Те же компании, которые увеличили стоимость масок где-то в десятки раз, те же, допустим, аптечные пункты, в которых цены растут, – это, конечно, плохо, потому что, я понимаю, что с одной стороны нужно увеличить оборот, чтобы больше лекарств, но цены – конечно, это нечестные люди, нечестные бизнесмены".

Лейтмотив журналистского расследования датской газеты: грипп удачно раскрутили в новостях во всем мире. Итог – 7 миллиардов евро чистой прибыли на одной лишь вакцине.

Постоянно подогреваемый интерес – именно поэтому мадам министр здравоохранения Франции вынуждена была сама уколоться публично и теперь каждую неделю дает пресс-конференции, что там с гриппом. По данным французских газет, количество доз вакцины, закупленной Парижем, превышает население страны.

Врачи уверены, что грипп опасен и лучше переоценить угрозу. С одной стороны, пишет "Дейли Телеграф", каждый четвертый школьник в Британии переболел гриппом A(H1N1), лечился от гриппа обычными средствами и благополучно выздоровел. С другой – только в этом месяце и только в Британии в тяжелом состоянии в больницы попали 530 человек.

Александр Чучалин, директор НИИ пульмонологии РФ, председатель правления МОО "Российское респираторное общество", академик РАМН: "Вы знаете, в чем дело, не надо здесь делать тревогу. Каждый год люди умирают от гриппа. На сегодняшний день мы не располагаем данными, которые говорят, что смертность выше, чем от сезонного гриппа в 2006-2007 годах".

Гриппозное чаепитие в лондонском сквере. Здесь следуют самому простому совету из телевизора: не ждите зимней волны эпидемии, переболейте в легкой форме и живите спокойно. Это просто грипп.

Importance of background rates of disease in assessment of vaccine safety during mass immunisation with pandemic H1N1 influenza vaccines

Lancet. 2009 Dec 19;374(9707):2115-2122.
doi: 10.1016/S0140-6736(09)61877-8. Epub 2009 Oct 31.
https://www.ncbi.nlm.nih.gov/pmc/articles/PMC2861912/

Because of the advent of a new influenza A H1N1 strain, many countries have begun mass immunisation programmes. Awareness of the background rates of possible adverse events will be a crucial part of assessment of possible vaccine safety concerns and will help to separate legitimate safety concerns from events that are temporally associated with but not caused by vaccination.

We identified background rates of selected medical events for several countries. Rates of disease events varied by age, sex, method of ascertainment, and geography. Highly visible health conditions, such as Guillain-Barré syndrome, spontaneous abortion, or even death, will occur in coincident temporal association with novel influenza vaccination.

On the basis of the reviewed data, if a cohort of 10 million individuals was vaccinated in the UK, 21.5 cases of Guillain-Barré syndrome and 5.75 cases of sudden death would be expected to occur within 6 weeks of vaccination as coincident background cases. In female vaccinees in the USA, 86.3 cases of optic neuritis per 10 million population would be expected within 6 weeks of vaccination. 397 per 1 million vaccinated pregnant women would be predicted to have a spontaneous abortion within 1 day of vaccination.

РИА НОВОСТИ

РФ может остановить членство в ВОЗ в случае сговора с фармкомпаниями

РИА Новости, 27 ноября 2009, 14:35
https://ria.ru/20091127/195797321.html

Москва: Появившиеся ранее в западных СМИ сообщения о коррупционном сговоре Всемирной организации здравоохранения (ВОЗ) с фармацевтическими компаниями необходимо проверить, в случае подтверждения этих данных Россия может приостановить свое членство в организации, считает член комиссии Госдумы РФ по законодательному обеспечению противодействия коррупции единоросс Игорь Баринов.

Согласно сообщениям некоторых СМИ, консультанты ВОЗ получали деньги от фармацевтических компаний, что могло повлиять на решение организации объявить пандемию свиного гриппа.

ВОЗ 11 июня впервые более чем за 40 лет официально объявила о введении шестого, максимального уровня угрозы пандемии в связи со стремительным распространением по миру гриппа A/H1N1.

По мнению Баринова, Россия не может оставить без реакции обвинения в адрес ВОЗ. "Организацию подозревают в коррупции. Нам необходимо провести тщательное всестороннее расследование, прежде чем принимать какое-либо решение", - сказал он журналистам в пятницу.

"Если информация подтвердится, в этом случае нужно ставить вопрос о целесообразности участия России в работе ВОЗ, вплоть до приостановления членства", - сказал он.

По его данным, Россия потратила на борьбу с новым вирусом более 4 миллиардов рублей, которые, как считает парламентарий, можно было бы расходовать на решение других актуальных проблем.

Баринов призвал начать расследование в ВОЗ через российского представителя в этой организации, члена исполнительного комитета ВОЗ Владимира Стародубова.

"Заслуги ВОЗ в борьбе с малярией, оспой, ВИЧ/СПИД в 20 веке никто не ставит под сомнение, но сейчас надо выяснить, не поражена ли сама ВОЗ вирусом коррупции, насколько обоснованы ее рекомендации, можно ли ей беспрекословно доверять", - считает парламентарий.

В свою очередь, главный государственный санитарный врач РФ, руководитель Роспотребнадзора Геннадий Онищенко, выступая в пятницу на межведомственном совещании в Генпрокуратуре РФ, посвященном соблюдению законодательства в сфере обращения лекарственных средств, тоже заявил о наличии сговора во время борьбы со свиным гриппом в мире.

"Одна уважаемая международная организация с самого начала взяла курс на маркетинг одного из препаратов, который не давал российским производителям позиционировать себя на рынке лекарств", - сказал он и отметил, что Россия "не позволила" создать "монополию", которая "навязывалась с помощью иностранных препаратов".

Всемирная организация здравоохранения, объявив пандемию свиного гриппа в мире, на первом этапе настоятельно рекомендовала всем странам использовать для борьбы с вирусом препарат "Тамифлю" швейцарского производства.

Число лабораторно подтвержденных случаев заражения гриппом A/H1N1 в мире, по состоянию на 15 ноября, превысило 525 тысяч, 6,75 тысячи заболевших скончались, сообщается в опубликованном 20 ноября заявлении Всемирной организации здравоохранения (ВОЗ). В пресс-релизе отмечается, что, поскольку многие страны перестали вести индивидуальный учет случаев заражения гриппом A/H1N1, реальное число больных может значительно превышать цифру, представленную ВОЗ.

Россия может остановить членство в ВОЗ в случае подтверждения сговора организации с фармкомпаниями

News.ru, 27 ноября 2009 г., 15:44

https://web.archive.org/web/20111229105106/http://newsru.com/russia/27nov2009/vozz.html

Появившиеся в западных СМИ сообщения о коррупционном сговоре Всемирной организации здравоохранения (ВОЗ) с фармацевтическими компаниями необходимо проверить, в случае подтверждения этих данных Россия может приостановить свое членство в организации, считает член комиссии Госдумы РФ по законодательному обеспечению противодействия коррупции единоросс Игорь Баринов.

Напомним, согласно сообщениям некоторых СМИ, консультанты ВОЗ получали деньги от фармацевтических компаний, что могло повлиять на решение организации - впервые более чем за 40 лет – официально объявить о введении шестого, максимального уровня угрозы пандемии в связи со стремительным распространением по миру гриппа A/H1N1. К выводу, что пандемия свиного гриппа может оказаться самой грандиозной коррупционной аферой нашего времени, пришли журналисты датской газеты Information, изучившие связи экспертов ВОЗ с ведущими мировыми фармацевтическими компаниями, обогатившимися на продаже препаратов против этой болезни.

ВОЗ, объявив пандемию свиного гриппа в мире, на первом этапе настоятельно рекомендовала всем странам использовать для борьбы с вирусом препарат "Тамифлю" швейцарского производства. Напомним, этот препарат вызвал нарекания в России из-за его возможных побочных эффектов. В то же время минздрав Украины обвинили в том, что он делает неоправданно масштабные закупки препарата "Тамифлю".

По мнению Баринова, Россия не может оставить без реакции обвинения в адрес ВОЗ. "Организацию подозревают в коррупции. Нам необходимо провести тщательное всестороннее расследование, прежде чем принимать какое-либо решение", - сказал он журналистам в пятницу. "Если информация подтвердится, в этом случае нужно ставить вопрос о целесообразности участия России в работе ВОЗ, вплоть до приостановления членства", - сказал он.

По его данным, Россия потратила на борьбу с новым вирусом более 4 миллиардов рублей, которые, как считает парламентарий, можно было бы расходовать на решение других актуальных проблем, сообщает РИА "Новости".

Баринов призвал начать расследование в ВОЗ через российского представителя в этой организации, члена исполнительного комитета ВОЗ Владимира Стародубова. "Заслуги ВОЗ в борьбе с малярией, оспой, ВИЧ/СПИД в 20 веке никто не ставит под сомнение, но сейчас надо выяснить, не поражена ли сама ВОЗ вирусом коррупции, насколько обоснованы ее рекомендации, можно ли ей беспрекословно доверять", - считает парламентарий.

В свою очередь главный государственный санитарный врач РФ, руководитель Роспотребнадзора Геннадий Онищенко, выступая в пятницу на межведомственном совещании в Генпрокуратуре РФ, посвященном соблюдению законодательства в сфере обращения лекарственных средств, тоже заявил о наличии сговора во время борьбы со свиным гриппом в мире.

"Одна уважаемая международная организация с самого начала взяла курс на маркетинг одного из препаратов, который не давал российским производителям позиционировать себя на рынке лекарств", - сказал он и отметил, что Россия "не позволила" создать "монополию", которая "навязывалась с помощью иностранных препаратов".

Впрочем, по многим заявлениям врачей, "Тамифлю" пока является единственным в мире препаратом, способным бороться со свиным гриппом. Однако ВОЗ подтвердила уже 39 случаев заражения вирусом, который оказался устойчивым к "Тамифлю".

Между тем число лабораторно подтвержденных случаев заражения гриппом A/H1N1 в мире, по официальным данным на 15 ноября, превысило 525 тысяч, 6750 заболевших скончались, сообщалось в опубликованном 20 ноября заявлении ВОЗ. В пресс-релизе отмечалось при этом, что, поскольку многие страны перестали вести индивидуальный учет случаев заражения гриппом A/H1N1, реальное число больных может значительно превышать цифру, представленную ВОЗ.

Генпрокуратура узнала о сговоре во Всемирной организации здравоохранения

GZT.ru, 27 ноября 2009, 16:42
https://web.archive.org/web/20091129015006/http://www.gzt.ru/topnews/world/274155.html

Россия может выйти из ВОЗ, если подтвердятся слухи, что пандемия гриппа A/H1N1 на самом деле – не более чем успешная пиар-акция.

Геннадий Онищенко обвинил ВОЗ в маркетинге одного из препаратов против гриппа A/H1N1. Тем временем в Госдуме говорят, что Россия может выйти из ВОЗ, если подтвердится, что пандемия свиного гриппа на самом деле - не более чем успешная пиар-акция.

Главный санитарный врач России и руководитель Роспотребнадзора Геннадий Онищенко, судя по всему, считает слухи о сговоре между Всемирной организацией здравоохранения (ВОЗ) и ведущими фармацевтическими компаниями вполне правдоподобными. «Одна уважаемая международная организация с самого начала взяла курс на маркетинг одного из препаратов, который не давал российским производителям позиционировать себя на рынке лекарств»,- заявил он 27 ноября на межведомственном совещании в Генпрокуратуре РФ, посвященном соблюдению законодательства в сфере обращения лекарственных средств.

Очевидно, речь идет о препарате «Тамифлю» швейцарского производства, который консультанты ВОЗ во всех странах настойчиво рекомендовали применять при первых симптомах заболевания. Онищенко, как передает РИА Новости, подчеркнул, что Россия не позволила создать «монополию», которая «навязывалась с помощью иностранных препаратов».

Слишком быстрая пандемия

О сговоре Всемирной организации здравоохранения и производителей лекарственных препаратов первой сообщила датская газета Dagbladet Information. В статье, опубликованной 17 ноября, сообщалось, консультанты ВОЗ, активно поддерживавшие идею массовой вакцинации, получали значительные вознаграждения за продвижение определенных препаратов. Одним из них был глава экспертной группы Альберт Остенхауз, известный как «доктор Флю». По утверждению датских журналистов, он сотрудничал сразу с несколькими фармацевтическими компаниями, производящими вакцины от свиного гриппа. Еще несколько консультантов ВОЗ помимо Остенхауза совмещали свою деятельность с работой в таких фармацевтических копаниях, как Roche, RW Johnson, SmithKline и Beecham Glaxo Wellcome.

Dagbladet Information также обратила внимание на стенограммы заседаний ВОЗ, состоявшихся 10 и 11 июня 2009 года и посвященных распространению свиного гриппа. В документах указывается, что на заседании присутствовали консультанты ВОЗ, министры, представители профессиональных медицинских ассоциаций и исследовательских институтов, а также некие «эксперты из международных организаций». Под этой формулировкой, как считают журналисты, скорее всего, скрываются представители фармацевтической промышленности.

Даже если на самом заседании они не имели права голоса, то неизвестно, о чем они говорили с руководством ВОЗ в кулуарах, пишет газета. По информации журналистов, на заседании совершенно точно присутствовали представители всех ведущих производителей вакцины от

свиного гриппа. Есть веские снования полагать, что именно они повлияли на то, что по итогам заседания ВОЗ впервые более чем за 40 лет официально объявила о введении пандемии гриппа A/H1N1.

«Фармацевтические компании получили заказы на изготовление вакцины со всего мира стоимостью 55 млрд долларов. Эти громадные средства использовались для вакцинации против заболевания, которое не кажется особенно опасным,- и в любом случае гораздо менее смертоносным, чем обычный сезонный грипп»,- говорится в статье. По мнению журналистов, весьма значительная доля этих средств досталась тем, кто добился введения пандемии свиного гриппа.

Нидерланды проверят «доктора Флю»

Информация о возможной договоренности между ВОЗ и производителями уже вызвала реакцию в Европе. Те же датские журналисты призывают правительство взять на себя инициативу и вывести мошенников на чистую воду. Сама Дания потратила на вакцину от гриппа A/H1N1 162 млн долларов.

А правительство Нидерландов сообщило, что намерено экстренно расследовать деятельность Альберта Остенхауза по подозрениям в финансовой заинтересованности в пропаганде вакцинацию против гриппа.

Россия обойдется без ВОЗ

Россия также не может оставить без реакции обвинения в адрес ВОЗ, но прежде чем принимать какое-либо решение необходимо провести тщательное всестороннее расследование. Об этом в пятницу заявил член комиссии Госдумы по законодательному обеспечению противодействия коррупции Игорь Баринов. По его словам, в случае, если информация о сговоре подтвердится, Россия может поставить вопрос о целесообразности своего участия в работе ВОЗ, вплоть до приостановления членства в организации.

«Заслуги ВОЗ в борьбе с малярией, оспой, ВИЧ/СПИД в 20 веке никто не ставит под сомнение, но сейчас надо выяснить, не поражена ли сама ВОЗ вирусом коррупции, насколько обоснованы ее рекомендации, можно ли ей беспрекословно доверять»,- отметил депутат. Те 4 млрд рублей, которые Россия потратила на борьбу с новым вирусом, можно было бы расходовать на решение других актуальных проблем, добавил он.

THE FLU CASE

La Russie pourrait suspendre son adhésion à l'OMS

The Flu Case, 28 novembre 2009, 09h54

https://web.archive.org/web/20100102035628/http://theflucase.com/index.php?option=com_content&view=article&id=2100%3Arussia-could-withdraw-from-who-over-swine-flu-corruption&catid=41%3Ahighlighted-news&Itemid=105&lang=en

Grippe A: un député de «Russie unie» demande que la Russie suspende son adhésion à l'OMS (newsru.com 28-11-2009)

Article repris sur le site du KPRF sous le titre: Encore un sale coup des capitalistes, ou comment les laboratoires pharmaceutiques se font une fortune grâce à la «grippe porcine»

Il est absolument urgent de vérifier les informations parues dans les médias occidentaux sur la collusion présumée entre l'organisation mondiale de la santé (OMS) et les compagnies pharmaceutiques. Si ces soupçons étaient confirmés, la Russie pourrait suspendre son adhésion à l'organisation, déclare Igor Barinov, membre de la commission de la douma d'État en charge des affaires de corruption.

D'après certaines sources, les experts de l'OMS ont reçu de l'argent des compagnies pharmaceutiques, et c'est ce qui aurait conduit cette organisation, pour la première fois depuis plus de 40 ans, à déclarer officiellement le niveau six d'alerte de pandémie en rapport avec la diffusion mondiale rapide de la grippe A/H1N1. Ce sont des journalistes du journal danois Information qui, après avoir étudié les liens des experts de l'OMS avec les grandes compagnies pharmaceutiques mondiales, en ont conclu que la pandémie de grippe porcine pourrait être l'affaire de corruption la plus grandiose de notre époque.

L'OMS, après avoir déclaré l'état de pandémie de grippe porcine dans le monde, a dans une première étape recommandé fortement à tous les pays d'utiliser dans la lutte contre le virus le produit Tamiflu des laboratoires suisses. Rappelons que ce produit a suscité des critiques en Russie à cause de ses effets secondaires possibles. En même temps, le ministère de la santé ukrainien a été accusé de faire des achats excessifs et injustifiés de Tamiflu.

D'après Barinov, la Russie ne peut rester indifférente aux accusations portées contre l'OMS. «L'organisation est suspectée de corruption. Nous devons absolument mener une enquête minutieuse avant de prendre toute décision» - a-t-il déclaré vendredi aux journalistes. «Si l'information est confirmée, nous devrons poser la question du bien-fondé de la participation de la Russie de l'OMS, et le cas échéant suspendre notre adhésion».

D'après les chiffres qu'il cite, la Russie a dépensé pour la lutte contre le nouveau virus plus de 4 milliards de roubles, qui, selon le député, auraient pu être dépensés à meilleur escient, annonce RIA Novosti.

Barinov a suggéré de faire mener l'enquête à l'OMS par le représentant russe dans cette organisation, le membre du comité exécutif de l'OMS Vladimir Starodoubov. «Personne ne remet en cause les services rendus au XXe siècle par l'OMS dans la lutte contre la malaria, la variole, le sida, mais aujourd'hui il faut se demander si cette organisation n'est pas frappée elle-même par le virus de la corruption, et dans quelle mesure ces recommandations sont fondées, dans quelle mesure on peut lui faire confiance» - estime le député.

De son côté, le directeur de l'institut de veille sanitaire Guennadi Onichtchenko, prenant la parole vendredi à une conférence du parquet général de la fédération de Russie consacrée au respect de la législation dans le domaine pharmaceutique, a déclaré lui aussi que la lutte contre la grippe porcine dans le monde prend l'allure d'un complot.

THE FLU CASE

Russia Could withdraw from WHO over Swine Flu Corruption

The Flu Case, 28 November 2009

https://web.archive.org/web/20100102035628/http://theflucase.com/index.php?option=com_content&view=article&id=2100%3Arussia-could-withdraw-from-who-over-swine-flu-corruption&catid=41%3Ahighlighted-news&Itemid=105&lang=en

A Russian deputy of the Duma has called for Russia to withdraw from the WHO if an investigation into the alleged collusion between the WHO and pharmaceutical companies on the swine flu scandal proves to be accurate, according to reports in the European media.

Igor Barinov, Member of the Commission of the State Parliament (Duma) in Charge of Corruption, said that there needed to be an investigation into whether experts advising WHO received money from pharmaceutical industry and whether this influenced WHO to declare a pandemic level 6 emergency for the first time in 40 years in spite of the fact that the swine flu is neither lethal nor spreading rapidly.

Danish journalists belonging to "Information" concluded that the swine flu could be the biggest case of corruption in our era after examining links between experts of WHO and the pharmaceutical companies.

WHO recommended the purchase of the controversial Swiss-based Roche’s Tamilfu in spite of evidence the drug causes serious side effects. The Ukrainian ministry for health bought large and excessive stocks of Tamiflu.

"The organization is suspected of corruption. We certainly must carry out a meticulous inquiry before making any decision," Barinov declared on Friday to journalists.

"If the information is confirmed, we will have to put the question of whether it makes sense for Russia to belong to WHO, and to suspend our membership if necessary".

Russia has spent more than 4 billion roubles so far on the swine flu.

Barinov suggested making the head of the investigation of WHO, the Russian representative in this organization, the member of the executive committee of WHO, Vladimir Starodoubov.

"Nobody calls into question the services rendered in the 20th century by WHO in the fight against the malaria, AIDS, but today it should asked whether this organization is not struck itself by the virus of corruption, and up to what point these recommendations are founded, up to what point can we trust it," said Barinov.

The director of the Russian National Sanitary Surveillance Institute Guennadi Onichtchenko said in a meeting with the general prosecutor of the federation of Russia for legislation in the pharmaceutical field that the fight against the swine flu in the world has the characteristics of a plot.

There is also mounting evidence WHO was instrumental in spreading AIDs.

Experter samarbetar med industrin

Svenska Dagbladet, 30 november 2009, 01.00.
http://www.svd.se/nyheter/inrikes/artikel_3866171.svd

Pandemi. Rader med experter hjälper WHO att hantera hotet från svininfluensan. Men flera av rådgivarna har kopplingar till läkemedels-industrin, visar SvD:s granskning. Kommittén som ger råd om själva pandemin är hemlig.

Genève/Stockholm.

En central grupp sedan svininfluensans utbrott i våras är WHO:s "Emergency Committe". Baserat på information från denna kriskommittée har WHO:s generaldirektör Margaret Chan fattat beslut om olika pandeminivåer.
Efter kommitténs fjärde möte den elfte juni 2009 drog Margaret Chan slutsatsen att kriterierna för en pandemi uppfyllts.
"Efter rådgivning från kriskommittén beslutar WHO:s generaldirektör Margaret Chan att gå från fas fem till sex", skrev WHO i ett pressmeddelande.
"WHO har nu nära dialog med tillverkare av influensavaccin, och full kapacitet ska snart vara uppnådd för att försäkra största möjliga tillgång till pandemivaccin inom de närmaste månaderna", hette det vidare.

Vad är denna kriskommitté vars slutsatser ligger bakom pandemibeslutet som också utlöste storskalig vaccinproduktion?
– Kommittén sammankallas av WHOs generaldirektör vid behov för att ge råd om internationella sjukdomsutbrott. De träffades första gången 25 april i år. Kommittén består av 18 medlemmar och är enbart rådgivande, säger Gregory Hartl, talesman för svininfluensan vid WHO.
Han betonar att WHO-chefen får råd från världens främsta hälsoexperter genom kommittén, men att beslutet att deklarera en pandemi "helt och hållet är hennes eget".

Vilka är medlemmarna i kommittén?
– Namnen på medlemmarna i kommittén är hemliga. Man vill inte att de ska kunna utsättas för påtryckningar utifrån. De är valda utifrån sina expertkunskaper om influensa, virusspridning och sjukdomskontroll, säger Hartl.

Varför är namnen hemliga? Vilka slags påtryckningar riskerar medlemmarna?
– Jag kan inte gå in på det. Men det viktiga är att medlemmarna i kommittén inte behöver ta hänsyn till någon eller någonting utanför kommittén i sin rådgivning till WHO:s generaldirektör, säger Gregory Hartl.

Har någon medlem i kommittén koppling till eller samarbete med läkemedelsindustrin?
– Jag vet inte vilka medlemmarna är. Jag tror att kontroller görs om de har kopplingar till läkemedelsindustrin.

Bör inte WHO vara transparent när det gäller hur beslut fattas om sjukdomar som berör miljontals människor?

– I kampen mot denna epidemi måste man samarbeta med många parter. Det inkluderar regeringar, frivilligorganisationer och läkemedelsindustrin. Vi måste hitta de bästa lösningarna för att skydda människors liv. Att rädda liv är allra viktigast för oss, säger Gregory Hartl.

Han tillägger att "vi frågar om intressekonflikter och får uppgifter om detta".
Han säger också att det finns flera kommittéer som ger råd om olika aspekter kring svininfluensan och hur man kan bekämpa den.
– Dessa kommittéer undviker intressekonflikter, säger han.

Men en titt på dessa kommittér visar att det inte alltid stämmer. När det gäller influensa och vaccin har WHO bland annat Sage-kommittén samt Ad hoc Policy Advisary Working Group on Influenza A (H1N1) till hjälp.

Tre av Sages femton medlemmar har kontakter med läkemedelsindustrin. Bland annat har de fått pengar och stöd av de ledande vaccinföretagen.

Två oberoende externa experter på Sages möten i Genève har av den danska tidningen Information avslöjats ha fått rådgivarpengar från läkemedelsföretag (se grafik under artikeln).

I Ad Hoc-kommittén sitter också som oberoende expert en professor och världsledande virusforskare som fått kritik i tidskriften Science för att han äger två bioteknikföretag som jobbar med influensavaccin.

När det gäller beslutet att deklarera en pandemi har dock vare sig Ad Hoc-kommittén eller Sage "spelat någon som helst roll", säger Gregory Hartl.

– Margaret Chan kan bara ta rådgivning av kriskommittén och medlemsländerna. Men beslutet om en pandemi är enbart hennes, säger han.

THE FLU CASE

Inger Atterstam

Swine Flu Gate: Is Virologist Albert Osterhaus the Ringleader?

The Flu Case, 3 December, 12:56

https://web.archive.org/web/20100102041114/http://theflucase.com/index.php?option=com_content&view=article&id=2171%3Aswine-flu-gate-is-virologist-albert-osterhaus-the-ringleader&catid=1%3Alatest-news&Itemid=64&lang=en

According to Russian, Danish and now Swedish newspapers, the Svenska Dagbladet, many of the "independent experts" who sit on important WHO committees and who were instrumental in the fake swine flu scare have financial links with the pharmaceutical industry that stand to make billions from the scam.

Albert Osterhaus, a professor for virologie at Erasmus University in The Netherlands, and a key advisor of WHO and EU, is under investigation for having concealed slush funds from pharmaceutical companies, according to Polskaweb.

Polskaweb reports a Dutch parliamentary committee of inquiry has been launched into the connection between the large sums of money paid by big pharma into Osterhaus' private bank accounts and his role in ratcheting up the swine flu scare to allow a pandemic level 6 declaration – something which, in turn, has allowed big pharma to reap huge profits through the sale of toxic pandemic vaccines.

Osterhaus also played a leading role in creating the bird flu scare by maintaining that he had proved that the bird flu virus could be transmitted to humans.

The bird flu alarmism resulted in health minister pushing through pandemic plans that strip people of their constitutional rights and also to profits of 100 million euros for Roche.

But Osterhaus appears to have financial links not just to Roche but also to GSK, Aventis and Baxter.

The Dutch investigation is being extended to health officials, politicans, doctors and journalists.

According to Polskaweb, big pharma has earned 40 billion dollars already from the swine flu scam.

By putting mercury and squalene into the swine flu jab, WHO and big pharma have shown, however, that their intention was to do more than just earn huge amounts of money by staging a fake pandemic using massaged data and skewed scientific evidence.

The dangerous ingredients in the jab prove that their intention was to cause damage and death.

Danish journalists have also looked at the role of Dr. Frederick Hayden, an advisor of WHO and in charge of the special strategic group (LEGEND) which in July floated the plan of giving every person in the world two doses of the swine flu jab.

Hayden is allegedly on the payroll of Roche, RW Johnson, SmithKline Beecham and Glaxo Wellcome.

Other "experts" who appear to be pushing junk science or even actively looking for virulent genes in the Swine Flu Gate, are John Oxford and Bruno Lina.

Both of these play leading roles in WHO and the EU.

As Climate Gate and now Swine Flu Gate show, the UN, WHO and EU are operating as criminal enterprises and they need to be called to account.

Swine flu labelled a conspiracy

PharmaTime, 2 December 2009
https://pharmatimes.com/news/swine_flu_labelled_a_conspiracy_984175/

The swine flu pandemic has been named as the "most ambitious scam and corruption of our time" after pharma has been found to be in bed with the World Health Organisation.

Journalists from Denmark have reported links between the World Health Organisation and pharmaceutical companies where firms have been covertly paying top WHO scientists. In the meantime, pharma profits from flu drugs have soared.

The journalists from the newspaper *Information* claim the public and political hysteria to swine flu is a result of an efficient public relations campaign, spearheaded by the WHO experts that have been prejudiced by pharma's ready cash.

The lead target in the allegations is Dutch doctor Albert Ostenhaus, who has promoted the need for vaccinations through the WHO and the media and headed a panel that advised the WHO to announce that swine flu had reached pandemic level. Reports claim Ostenhaus is paid by several vaccine manufacturers and the Netherlands government is believed to be investigating his activities.

Other WHO advisors are understood to also advise big pharma and have been allegedly concealing their pharma-funded salaries.

Meanwhile, further questions have been raised about the WHO's independence over the H1N1 flu virus after various documents found medicines and vaccinations were mentioned more than 40 times while traditional hand washing and the use of masks to combat the disease were only mentioned twice.

The pharma industry is expected to make between seven and 10 billion euros in 2009 from the sales of swine flu related drugs, according to JP Morgan.

Polskaweb News

Tötet der H1N1- Impfstoff?
Russland droht WHO

PolskaWeb News, 5 December 2009
https://web.archive.org/web/20091215032125/http://polskaweb.eu/index2.php?option=com_content&task=view&id=3013&pop=1&page=0&Itemid=419

Russland fordert Untersuchung wegen Korruptionsverdacht bei WHO Berlin - Jeder ist in erster Linie für seine Gesundheit selbst verantwortlich, doch viele Menschen sind gezwungen diese Verantwortung auch für andere zu übernehmen. Kinder oder ältere Leute zum Beispiel die nicht selbst entscheiden können oder wollen sind somit ihren Erziehungsberechtigten oder einem Arzt voll ausgeliefert, wenn es um die möglicherweise tödlichen Folgen von Impfungen gegen den Schweinegrippe- Virus (H1N1) geht. Wir warnen diesbezüglich dringendst vor übereilten Entscheidungen für sich und andere, denn die bis jetzt bekannten Grippemittel scheinen weder sicher noch hilfreich zu sein und ihre Hersteller stehen international bereits unter Korruptionsverdacht. Heute sind wieder Menschen in Deutschland nach Impfungen mit Pandemrix gestorben, ebenso in Italien und Slowenien und wahrscheinlich auch vielen anderen Ländern. In Dänemark, Holland, Russland und Polen ermitteln Journalisten und Politiker bereits gegen mögliche Verantwortliche einer nicht mehr auszuschliessenden gigantischen Verschwörung und Korruption.

Warnung vor Behörden, Instituten und Medien

Meldungen der Weltgesundheitsorganisation WHO, Gesundheitsämtern, Einrichtungen wie dem Robert-Koch- und Paul-Ehrlich-Institut sowie Medien wie z.B. Bild-Zeitung, Welt, Focus, Rheinische Post und selbst der ARD- Tageschau sollten Sie nicht blind vertrauen, denn durch ihre anhaltende Panikmache bez. der dubiosen Schweingrippe, stehen sie gleichfalls unter Verdacht Gelder von den Produzenten der Impfstoffe erhalten zu haben. Es ist definitv gelogen, dass Impfstoffe knapp seien und es deshalb Wartelisten gebe, die Impfung gegen Schweinegrippe völlig harmlos sei und die Grippe dagegen gefährlich. Es ist sogar nicht auszuschliessen, dass in Deutschland bereits mehr Menschen durch Impfungen starben als an den Folgen einer dubiosen Schweinegrippe. Die großen Pharma-Produzenten pflegen nur ca. 11 Prozent ihres Umsatzes in die Forschung zu stecken, aber 37 % in die PR für ihre Produkte. Selbst Milliarden Bestechungsgelder könnten somit bereits geflossen sein.

Drohungen aus Russland gegen die WHO

Während in Russland die Ausbreitung einer Grippeepidemie bereits unter Kontrolle der Gesundheitsbehörden zu sein scheint und die Zahlen der Erkrankten zurückgehen, sind jetzt auch hier die WHO und die Pharmaindustrie unter Korruptionsverdacht geraten. Beide versuchen schon seit Monaten gemeinsam, mittels "druckvollen Empfehlungen", Moskau zum Kauf des Anti-Virus-Präparates Tamiflu des schweizer Arzneimittelherstellers "Roche" zu bringen. Die russische Regierung hat aber, ebenso wie schon früher die polnische Gesundheitsministerin Kopacz, Bedenken gegen die angebliche Gefahr der Schweinegrippe geäussert und alle diesbezüglichen Gegenmittel folgerichtig in Frage gestellt.

Russland fordert internationale Untersuchung

Der Dumaabgeordnete und Vorsitzende des russischen Gesundheitsausschusses Igor Barinow hat den ständigen Vertreter Russlands bei der WHO angewiesen, Ermittlungen in Zusammenhang mit den sich mehrenden Korruptionsvorwürfen gegen die Organisation und der Pharmaindustrie anzustellen. "Es gibt schwerwiegende Vorwürfe wegen Korruption innerhalb der WHO. Eine internationale Untersuchung hierzu ist unabdinglich. Wir haben bereits 4 Milliarden Rubel im Kampf gegen die neue Grippe ausgegeben, dieses Geld hätte für wesentlich dringlichere Probleme ausgegeben werden können. Wenn sich derartige Vorwürfe von Verschwörung und Korruption bestätigen, könnte dies auch einen Austritt Russlands aus der WHO bedeuten" - sagte Barinow am Freitag und fügte hinzu, dass niemand an der Stichhaltigkeit der WHO im Kampf gegen Malaria, Pocken und HIV im zwanzigsten Jahrhundert zweifele, doch jetzt aber müsse geklärt werden, ob die Organisation selbst nicht mit Korrupten Subjekten infiziert sei.

"Polskaweb News" macht die Welt schon seit Monaten auf Ungereimtheiten um die Schweinegrippe aufmerksam. Leider werden die Behörden aber wieder erst reagieren wenn den Tätern ausreichend Zeit gelassen wurde, ihre Verbrechen zu verschleiern und Beweise zu vernichten. Lesen Sie hier mehr über die dubiosen Ereignisse um die angebliche tödliche Seuche (Bild-Zeitung).

WHO 'Swine Flu Pope' under investigation for gross conflict of interest

Financial Sense Editorials // Voltairenet, 9 December 2009
https://web.archive.org/web/20100106000416/http://financialsense.com/editorials/engdahl/2009/1208.html
https://www.voltairenet.org/article163240.html

The man with the nickname "Dr Flu", Professor Albert Osterhaus, of the Erasmus University in Rotterdam Holland has been named by Dutch media researchers as the person at the center of the worldwide Swine Flu H1N1 Influenza A 2009 pandemic hysteria. Not only is Osterhaus the connecting person in an international network that has been described as the Pharma Mafia, he is THE key advisor to WHO on influenza and is intimately positioned to personally profit from the billions of euros in vaccines allegedly aimed at H1N1.

Earlier this year the Second Chamber of the Netherlands Parliament undertook an investigation into alleged conflicts of interest and financial improprieties of the well-known Dr. Osterhaus. Outside of Holland and the Dutch media, the only note of the sensational investigation into Osterhaus' business affairs came in a tiny note in the respected British magazine, *Science*.

Osterhaus's credentials and expertise in his field were not in question. What is in question, according to a short report published by the journal *Science*, are his links to corporate interests that stand to potentially profit from the swine flu pandemic. *Science* carried the following brief note in its October 16, 2009 issue about Osterhaus:

"For the past 6 months, one could barely switch on the television in the Netherlands without seeing the face of famed virus hunter Albert Osterhaus talking about the swine flu pandemic. Or so it has seemed. Osterhaus, who runs an internationally renowned virus lab at Erasmus Medical Center, has been Mr. Flu. But last week, his reputation took a nosedive after it was alleged that he has been stoking pandemic fears to promote his own business interests in vaccine development. As *Science* went to press, the Dutch House of Representatives had even slated an emergency debate about the matter." [1]

On November 3, 2009 it appeared that Osterhaus emerged with at least the damage somewhat under control. An updated *Science* blog noted, "The House of Representatives of the Netherlands today rejected a motion asking the government to sever all ties with virologist Albert Osterhaus of Erasmus Medical Center in Rotterdam, who had been accused of conflicts of interest in his role as a government adviser. But Dutch health minister Ab Klink, meanwhile, announced a "Sunshine Act" compelling scientists to disclose their financial ties to companies." [2]

The Minister, Ab Klink, reportedly a personal friend of Osterhaus, [3] subsequently issued a statement on the ministry's website, claiming that Osterhaus was but one of many scientific advisers to the ministry on vaccines for H1N1, and that the Ministry "knew" about the financial interests of Osterhaus. [4] Nothing out of the ordinary, merely pursuit of science and public health, so it seemed.

More careful investigation into the Osterhaus Affair suggests that the world-renowned Dutch Virologist may be at the very center of a multi-billion Euro pandemic fraud which has used human beings in effect as human guinea pigs with untested vaccines and in cases now emerging, resulting in deaths or severe bodily paralysis or injury.

The 'Bird Shit Hoax'

Albert Osterhaus is no small fish. He stands at the global nexus of every major virus panic of the past decade from the mysterious SARS deaths in HongKong, where current WHO Director Margaret Chan got her start in her career as a local health official. According to his official bio at the European Commission, Osterhaus was engaged in April 2003, at the height of the panic over SARS (Severe Acquired Respiratory Syndrome) in investigation of the Hong Kong outbreak of respiratory illnesses. The EU report states, "he again showed his skill at moving fast to tackle a serious problem. Within three weeks he had proved that the disease was caused by a newly discovered coronavirus that resides in civet cats, other carnivorous animals or bats." [5]

Then Osterhaus moved on as SARS cases vanished from view, this time publicizing dangers of what he claimed was H5N1 Avian Flu. In 1997 he had already began sounding the alarm following the death in Hong Kong of a three-year-old who Osterhaus learned had had direct contact with birds. Osterhaus went into high gear lobbying across Holland and Europe claiming that a deadly new mutation of avian flu had jumped to humans and that drastic measures were required. He claimed to be the first scientist in the world to show that H5N1 could be transferred into humans. [6]

In a BBC interview in October 2005 on the danger of Avian Flu, Osterhaus declared, "…if the virus manages indeed to, to mutate itself in such a way that it can transmit from human to human, then we have a completely different situation, we might be at the start of the pandemic." He added, "there is a real chance that this virus could be trafficked by the birds all the way to Europe. There is a real risk, but nobody can estimate the risk at this moment, because we haven't done the experiments." [7] It never did manage to mutate, but he was ready to "do the experiments," presumably for a hefty fee.

To bolster his frightening pandemic scenario, Osterhaus and his lab assistants in Rotterdam began assiduously assembling and freezing samples of, well, bird shit, in an attempt to build a more scientific argument. He claimed that at certain times of the year up to 30% of all European birds acted as carriers of the deadly avian virus, H5N1. He also claimed that farmers working with hens and chickens were then exposed. Osterhaus briefed journalists who dutifully noted his alarm. Politicians were alerted. He wrote papers proposing that the far away deaths in Asia from what he termed H5N1 were coming to Europe, presumably on the wings or in the innards of deadly sick infected birds. He claimed that migratory birds were carrying the deadly new disease as far west as Rügen and Ukraine. [8] He conveniently ignored the fact that birds do not migrate east to west but rather north to south.

Osterhaus' Avian Flu alarm campaign really took off in 2003 when a Dutch veterinary doctor became ill and died. Osterhaus claimed the death was from H5N1. He convinced the Dutch government to order slaughter of millions of chickens. Yet no other infected persons died from the alleged H5N1. Osterhaus claimed that that was simply proof of the effectiveness of the preemptive slaughter campaign. [9]

Osterhaus claimed that bird feces were the source, via air bombardment or droppings, onto populations and birds below. That was the vehicle for the spread of the deadly new Asian strain of H5N1 he insisted.

There was only one problem with the now voluminous frozen samples of diverse bird excrement he and his associates had collected and frozen at his institute. There was not one single confirmed example of H5N1 virus found in any of his samples. At a May 2006 Congress of the World Organization for Animal Health (OIE), Osterhaus and his Erasmus colleagues were forced to admit that in testing 100,000 samples of their assiduously saved bird feces, they had discovered not one single case of H5N1 virus. [10]

At a WHO conference in Verona in 2008 titled "Avian influenza at the Human-Animal Interface," in a presentation to scientific colleagues undoubtedly less impressed by appeals to pandemic emotion than the non-scientific public, Osterhaus admitted that "A proper risk assessment of H5N1 as the cause of a new pandemic cannot be made with the currently available information." [11] By then, however, his sights were already firmly on other possible pandemic triggers to focus his vaccination activities.

Swine Flu and WHO corruption

When no mass wave of human deaths from Avian Flu materialized and after Roche, maker of Tamiflu, and GlaxoSmithKline had banked billions of dollars in profits from worldwide government stockpiling of their dangerous and reportedly ineffective antiviral drugs - Tamiflu by Roche and Relenza by GlaxoSmithKline - Osterhaus and other WHO advisers turned to other greener pastures.

By April 2009 their search seemed rewarded as La Gloria, a small Mexican village in Veracruz, reported a case of a small child ill with what had been diagnosed as "Swine Flu" or H1N1. With indecent haste the propaganda apparatus of the World Health Organization in Geneva went into gear with statements from the director-general Dr Margaret Chan, about a possible danger of a global pandemic.

Chan made such irresponsible statements as declaring "a public health emergency of international concern." [12] The further cases of outbreak at La Gloria Mexico were reported on one medical website as, "a ‘strange’ outbreak of acute respiratory infection, which led to bronchial pneumonia in some pediatric cases. According to a local resident, symptoms included fever, severe cough, and large amounts of phlegm." [13]

Notably those were symptoms which would make sense in terms of the proximity of one of the world’s largest pig industrial feeding concentrations at La Gloria owned by Smithfield Farms of the USA. Residents had picketed the Smithfield Farms site in Mexico for months complaining of severe respiratory problems from the fecal waste lagoons. That possible cause of the diseases in La Gloria apparently did not interest Osterhaus and his colleagues advising the WHO. The long-awaited "pandemic" that Osterhaus had predicted ever since his involvement with SARS in the Guandgong Province of China in 2003, was now finally at hand.

On June 11, 2009 Margaret Chan of WHO made the declaration of a Phase 6 "Pandemic Emergency" regarding the spread of H1N1 Influenza. Curiously in announcing it, she noted, "On present evidence, the overwhelming majority of patients experience mild symptoms and make a rapid and full recovery, often in the absence of any form of medical treatment." She then added, "Worldwide, the number of deaths is small…we do not expect to see a sudden and dramatic jump in the number of severe or fatal infections."

It later was learned that Chan acted, following heated debates inside WHO, on the advice of the scientific advisory group of WHO, or SAGE, the Strategic Advisory Group of Experts. One of the members of SAGE at the time and today was Dr. Albert "Mr Flu" Osterhaus.

Not only was Osterhaus in a key position to advocate the panic-inducing WHO "Pandemic emergency" declaration. He was also chairman of the leading private European Scientific Working group on Influenza (ESWI), which describes itself as a "multidisciplinary group of key opinion leaders in influenza [that] aims to combat the impact of epidemic and pandemic influenza." Osterhaus’ ESWI is the vital link as they themselves describe it, "between the World Health Organization (WHO) in Geneva, the Robert Koch Institute in Berlin and the University of Connecticut, USA."

What is more significant about the ESWI is that its work is entirely financed by the same pharma mafia companies that make billions on the pandemic emergency as governments around the world are compelled to buy and stockpile vaccines on declaration of a WHO Pandemic. The funders of ESWI include H1N1 vaccine maker Novartis, Tamiflu distributor, Hofmann-La Roche, Baxter Vaccines, MedImmune, GlaxoSmithKline, Sanofi Pasteur and others.

Not to lose the point, the world-leading virologist, official adviser on H1N1 to the governments of the UK and Holland, Dr Albert Osterhaus, head of the Department of Virology at the Erasmus Medical College of Rotterdam, also sat on the WHO’s elite SAGE and served as chairman at the same time of the pharma industry-sponsored ESWI, which in turn urged dramatic steps to vaccinate the world against the grave danger of a new Pandemic they insisted could rival the feared 1918 Spanish Flu pandemic.

The Wall Street bank, JP Morgan, estimated that in large part as a result of the WHO pandemic decision, the giant pharma firms that also finance Osterhaus' ESWI work, stand to reap some €7.5 to €10 billion in profits. [14]

A fellow member of WHO's SAGE is Dr Frederick Hayden, of Britain's Wellcome Trust and reportedly a close friend of Osterhaus. Hayden also receives money for "advisory" services from Roche and GlaxoSmithKline among other pharma giants involved in producing products related to the H1N1 panic.

Chairman of WHO's SAGE is another British scientist, Prof. David Salisbury of the UK Department of Health. He also heads the WHO H1N1 Advisory Group. Salisbury is a robust defender of the pharma industry. He has been accused by UK citizen health group One Click of covering up the proven links between vaccines and an explosive rise in infant autism as well as links between the vaccine Gardasil and palsy and even death. [15]

Then on September 28, 2009 the same Salisbury stated, "There is a very clear view in the scientific community that there is no risk from the inclusion of Thiomersal." The vaccine being used for H1N1 in Britain is primarily produced by GlaxoSmithKlilne. It contains the mercury preservative Thiomersol. Because of growing evidence that Thiomersol in vaccines might be related to autism in children in the United States, in 1999 the American Academy of Pediatrics and the US Public Health Service called for it to be removed from vaccines. [16]

Yet another SAGE member at WHO with intimate financial ties to the vaccine makers that benefit from SAGE's recommendations to WHO is Dr. Arnold Monto, a paid consultant to vaccine maker MedImmune, Glaxo and ViroPharma.

Even more, the meetings of the "independent" scientists of SAGE are attended by "observers" who include, yes, the very vaccine producers GlaxoSmithKline, Novartis, Baxter and company. One might ask if the SAGE are supposed to be the world's leading experts on flu and vaccines, why they would ask the vaccine makers to sit in.

In the past decade the WHO, in order to boost funds at its disposal entered into what it calls "public private partnerships." Instead of receiving its funds solely from member United Nations governments as its original purpose had been, WHO today receives almost double its normal UN budget in the form of grants and financial support from private industry. The industry? The very drug and vaccine makers who benefit from decisions like the June 2009 H1N1 Pandemic emergency declaration. As the main financiers of the WHO bureaucracy, naturally the Pharma Mafia and their friends receive what has been called "open door red carpet treatment" in Geneva. [17]

In an interview with *Der Spiegel* magazine in Germany, epidemiologist Dr. Tom Jefferson of the Cochrane Collaboration, an organization of independent scientists evaluating all flu related studies, noted the implications of the privatization of WHO and the commercialization of health:

"…one of the extraordinary features of this influenza – and the whole influenza saga – is that there are some people who make predictions year after year, and they get worse and worse. None of them so far have come about, and these people are still there making these predictions. For example, what happened with the bird flu, which was supposed to kill us all? Nothing. But that doesn't stop these people from always making their predictions. Sometimes you get the feeling that there is a whole industry almost waiting for a pandemic to occur.

Spiegel: Who do you mean? The World Health Organization (WHO)?

Jefferson: The WHO and public health officials, virologists and the pharmaceutical companies. They've built this machine around the impending pandemic. And there's a lot of money involved, and influence, and careers, and entire institutions! And all it took was one of these influenza viruses to mutate to start the machine grinding... [18]

When asked if the WHO had deliberately declared the Pandemic Emergency in order to create a huge market for H1N1 vaccines and drugs, Jefferson replied,

"Don't you think there's something noteworthy about the fact that the WHO has changed its definition of pandemic? The old definition was a new virus, which went around quickly, for which you didn't have immunity, and which created a high morbidity and mortality rate. Now the last two have been dropped, and that's how swine flu has been categorized as a pandemic." [19]

Conveniently enough, the WHO published the new Pandemic definition in April 2009 just in time to allow WHO, on advice of SAGE and others like Albert "Dr Flu" Osterhaus and David Salisbury, to declare the mild cases of flu dubbed H1N1 Influenza A to be declared Pandemic Emergency. [20]

In a relevant footnote, the *Washington Post* on December 8 in an article on the severity, or lack of same, of the world H1N1 "pandemic" reported that, "with the second wave of H1N1 infections having crested in the United States, leading epidemiologists are predicting that the pandemic could end up ranking as the mildest since modern medicine began documenting influenza outbreaks." [21]

Russian Parliamentarian and chairman of the Duma Health Committee, Igor Barinow has called on the Russian Representative to WHO in Geneva to order an official investigation into the growing evidence of massive corruption of the WHO by the pharmaceutical industry. "There are grave accusations of corruption within the WHO," said Barinow. "An international commission of inquiry is urgently required." [22]

ВОЙНА и МИР

Уильям Ф. Энгдаль

Коррупция в ВОЗ и свиной грипп

Война и Мир, 12 декабря 2009
http://www.kunpendelek.ru/library/westmed/information/corruption/
(Перевод статьи) F. William Engdahl
WHO 'Swine Flu Pope' under investigation for gross conflict of interest
Voltairenet, 9 December 2009
https://www.voltairenet.org/article163240.html

Уильям Ф. Энгдаль*, автор книг «Столетие войны», «Семена разрушения» и готовящейся к выходу на русском языке новой книги «Полный спектр доминирования»*

Человек, известный всем, как **«Доктор Грипп»**, профессор Альберт Остерхаус из Университета Эразмуса в Роттердаме, Голландия, был в 2009 году назван голландскими медийными исследователями, как человек, стоящий в центре всемирной истерии по поводу пандемии свиного гриппа H_1N_1.

Остерхаус - не только связующее звено в международной сети, которую называют «фармамафией**»**, он также является ключевым советником **ВОЗ** по гриппу и занимает пост, на котором извлекает персональную прибыль от миллиардов евро, выделяемых на вакцинирование, якобы, против гриппа H_1N_1.

Ранее в этом году вторая палата парламента Нидерландов провела расследование предполагаемого конфликта интересов и финансовых нарушений хорошо известного доктора Остерхауса. За пределами Голландии и голландских СМИ единственное упоминание об этом сенсационном расследовании бизнеса Остерхауса было в крохотной заметке в авторитетном британском журнале *Science*.

Полномочия Остерхауса и опыт в его области не обсуждались. Обсуждались, согласно опубликованного в журнале *Science* краткого сообщения, его связи с корпоративными интересами, которые стоят за потенциальными прибылями от пандемии свиного гриппа. *Science* предоставил следующие краткие сведения об Остерхаусе в своём выпуске от 16 октября 2009:

«В течение прошлых 6 месяцев достаточно было только включить телевидение в Нидерландах, чтобы увидеть там знаменитого охотника за вирусами Альберта Остерхауса, говорящего о пандемии свиного гриппа. Или так казалось. Остерхаус, который управляет всемирно известной вирусной лабораторией в Медицинском центре Эразмуса, называют «мистером Грипп». Но на прошлой неделе его репутация рухнула после того, как были выдвинуты обвинения, что он **раздувал страх пандемии**, чтобы продвинуть свои собственные деловые интересы в развитии вакцины. Когда номер *Science* пошёл в печать, голландская палата представителей даже наметила чрезвычайные дебаты об этом вопросе».[1]

Но 3 ноября 2009 года стало известно, что Остерхаус вышел сухим из воды, оставив ситуацию под контролем. Как было отмечено в обновлённом блоге *Science*, «палата представителей Нидерландов сегодня отклонила ходатайство, предлагающее правительству разорвать все связи с вирусологом Альбертом Остерхаусом из Медицинского центра Эразмуса в Роттердаме, который был обвинён в конфликте интересов, находясь на посту советника правительства».[2]

Министр **Аб Клинк**, по слухам, **личный друг Остерхауса**,[3] впоследствии разместил заявление на сайте министерства, в котором заявил, что Остерхаус являлся лишь одним из многих научных советников Министерства по вопросу вакцинирования против гриппа H_1N_1, и что министерство «знает» о финансовых интересах Остерхауса.[4]

Как оказалось, ничего необычного, все достижения науки и здравоохранения на службу человеку.

Более тщательное расследование связей **Остерхауса** позволяет предположить, что всемирно известный голландский вирусолог может стоять в самом центре **пандемического мошенничества**, стоимостью несколько миллиардов евро, в процессе которого человек использовался в качестве подопытного кролика для непроверенной вакцины, что в некоторых случаях приводило к гибели людей, причинению тяжких телесных повреждений или параличу.

Мистификация «птичье дерьмо»

Альберт Остерхаус - не мелкая рыбёшка. Он стоит за всеми основными случаями паники последнего десятилетия, вызванными новыми вирусами, начиная с таинственных смертей от атипичной пневмонии в Гонконге, где **нынешняя директор ВОЗМаргарет Чен** начинала свою карьеру в качестве чиновника местного здравоохранения.

В соответствии с его официальной биографией, находящейся в Европейской комиссии, в самый разгар паники по поводу атипичной пневмонии в апреле 2003 года Остерхаус принимал участие в расследовании вспышки болезни в Гонконге. В докладе ЕС говорится следующее:

«...Он вновь показал своё умение быстро реагировать и принимать меры к решению серьёзной проблемы. В течение трёх недель он доказал, что болезнь была вызвана новым коронавирусом, который обнаружен у африканской циветты и других хищных животных или летучих мышей...».[5]

Затем Остерхаус перенес своё внимание на пропаганду смертельной опасности птичьего гриппа H_5N_1, поскольку тема с атипичной пневмонией уже исчезла из поля зрения, потеряв актуальность. В 1997 году он уже начал бить тревогу в связи со смертями в Гонконге нескольких человек, которые, как узнал Остерхаус, имели прямой контакт с птицами.

Остерхаус моментально перешёл к продвижению в правительствах Голландии и всей Европы утверждения о новой смертельной мутации птичьего гриппа, который передаётся людям, и необходимости принятия радикальных мер по этому поводу. Он, по утверждениям, является первым учёным в мире, который стал отстаивать точку зрения, что вирус H_5N_1 может передаваться человеку.[6]

В своём интервью *BBC* об опасности птичьего гриппа в октябре 2005 года Остерхаус заявил что: «...если вирус на самом деле мутировал таким образом, что он теперь может передаваться от человека к человеку, то мы имеем совершенно иную ситуацию, мы, возможно, стоим на пороге пандемии». Он добавил, что «есть реальный шанс, что этот вирус может быть принесён птицами в Европу. Существует реальный риск, но пока никто не может точно оценить его, потому что мы ещё не делали эксперименты».[7]

Вирус так и не смог мутировать, но он уже тогда был готов «делать эксперименты», предположительно, за огромные деньги.

Чтобы подтвердить свой страшный сценарий пандемии, Остерхаус и его лаборант в Роттердаме начали усердно собирать и замораживать образцы птичьего дерьма, пытаясь получить более научное обоснование. Он утверждал, что в определённое время года до 30% всех европейских птиц могут являться носителями смертельного вируса птичьего гриппа H_5N_1.

Он также утверждал, что фермеры, работающие с курами и цыплятами, находятся в группе риска. Остерхаус проинформировал об этом журналистов, которые послушно озвучили его тревогу. Политики были предупреждены.

Он высказал предположение, что смерти в далёкой Азии от вируса, который он назвал H_5N_1, могут быть принесены в Европу, предположительно, инфицированными птицами. Он утверждал, что перелётные птицы несли новое смертоносное заболевание на запад вплоть до Рюгена и Украины.[8]

Ему было удобно игнорировать тот факт, что птицы не мигрируют с востока на запад, а только с севера на юг.

Широкую кампанию по «продвижению» птичьего гриппа, Остерхаус начал в 2003 году, когда заболел и умер голландский ветеринарный врач. Остерхаус утверждал, что смерть наступила в результате заражения H_5N_1.

Он убеждал голландское правительство, что необходимо уничтожить миллионы кур. Однако, до сих пор ни один инфицированный не умер от предполагаемого H_5N_1. Остерхаус утверждал, что это оказалось подтверждением эффективности кампании по уничтожению кур.[9]

Остерхаус утверждал, что источником заболевания являлся птичий помёт, который перелётные птицы распространяли путём воздушных «бомбардировок» земли и птиц, летящих ниже. Этот способ был основным для распространения нового смертоносного азиатского штамма H_5N_1, настаивал он.

Была только одна проблема с обширной коллекцией замороженных образцов птичьих экскрементов, которые он и его подручные собрали и сохранили в своём институте. **Ни в одном образце** не было подтверждено наличие вируса H_5N_1.

В мае 2006 года на Конгрессе Всемирной организации здоровья животных Остерхаус и его коллеги, вынуждены были признать, что в 100 000 проверенных образцах старательно сохранённого птичьего кала они не обнаружили **ни одного случая** наличия вируса H_5N_1.[10]

На конференции ВОЗ в Вероне в 2008 году, носившей название «Птичий грипп у людей и животных», в презентации своим коллегам, несомненно, менее впечатлённым криками о пандемии, чем ненаучная общественность, Остерхаус признал, что «надлежащая оценка возможности H_5N_1 оказаться причиной возникновения новой пандемии не может быть сделана на основе имеющейся в настоящее время информации».[11]

К тому времени, однако, его внимание было уже сосредоточено на другой возможной причине пандемии, где можно было раскрыть свои возможности по вакцинации.

Свиной грипп и коррупция в ВОЗ

Поскольку волна массовых человеческих смертей от птичьего гриппа не стала реальностью, а *Roche* и *GlaxoSmithKline* уже вложили миллиарды долларов в производство своих неэффективных и зачастую опасных антивирусных препаратов (*Tamiflu* от компании *Roche*, и *Relenza* от *GlaxoSmithKline*) в надежде на государственные закупки в огромных масштабах, Остерхаус и другие советники ВОЗ обратили свои взоры на другие «зелёные пастбища».

К апрелю 2009 года их поиски, были вознаграждены, поскольку из *La Gloria*, небольшой деревни в мексиканском штате Веракрус, сообщили о случае заболевания маленького ребёнка, которому был поставлен диагноз «свиной грипп» или H_1N_1.

С непристойной поспешностью пропагандистский аппарат **В**семирной **О**рганизации **З**дравоохранения в Женеве сделал устами Генерального директора д-ра **Маргарет Чен** заявление о возможной опасности глобальной пандемии.

Чен сделала следующее безответственное заявление: «угроза общественному здравоохранению, имеющая международное значение».[12]

О следующих случаях в *La Gloria* было сообщено на одном медицинском сайте следующее: «странная» вспышка острой респираторной инфекции, приводящей, в некоторых случаях, к бронхиальной пневмонии. По словам местных жителей, замечены следующие симптомы: сильный кашель, жар и обильная мокрота».[13]

Примечательно то, что симптомы имели смысл с точки зрения близости от одной из крупнейших свиноферм в мире, находящейся в *La Gloria* и принадлежащей компании *Smithfield Farms* из США.

Местные жители несколько месяцев пикетировали управление компании *Smithfield Farms* в Мексике с жалобами на проблемы с дыханием, связанные с огромным количеством свиного навоза в резервуарах рядом с фермой.

Но реальные причины заболевания в *La Gloria*, по-видимому, не интересовали Остерхауса и его коллег-консультантов **ВОЗ**. Долгожданная «пандемия», предсказанная Остерхаусом ещё во времена «эпидемии» атипичной пневмонии в китайской провинции Гуандун в 2003 году, теперь, наконец, случилась.

11 июня 2009 года **Маргарет Чен** из **ВОЗ** сделала заявление об опасности шестого уровня «угроза пандемии» в отношении распространения гриппа H_1N_1. Любопытно, что, объявив об этом, она отметила, что «на сегодняшний день подавляющее большинство пациентов испытывает лёгкие симптомы и достигает **быстрого и полного восстановления**, часто, в отсутствие какого-либо медицинского лечения».
Затем она добавила: «Во всём мире число смертей мал**о**... мы не ожидаем увидеть внезапного и резкого всплеска числа серьёзных или смертельных инфекций».

Позднее стало известно, что Чен сказала именно так после жарких дебатов внутри **ВОЗ**, последовав совету научно-консультативной группы **ВОЗ** или Стратегической консультативной группы экспертов. Одним из членов группы в то время и сейчас был д-р Альберт «доктор Грипп» Остерхаус.

Но Остерхаус был не только основным застрельщиком начала паники по поводу «угрозы пандемии» в **ВОЗ**. Он являлся также председателем ведущей частной «Европейской научной рабочей группы по гриппу» (*ESWI*), которая позиционирует себя следующим образом: «многопрофильная группу ключевых специалистов по гриппу, [которая] направляет свои усилия на борьбу с последствиями эпидемии и пандемии гриппа»

Эта рабочая группа Остерхауса является жизненно важным связующим звеном (как они сами её называют), «между Всемирной Организацией Здравоохранения в Женеве, Институтом Роберта Коха в Берлине и Университетом штата Коннектикут, США».

Ещё более интересным является то, что деятельность *ESWI* полностью финансируется теми же компаниями из «фармамафии», которые делают миллиарды на пандемии, поскольку, когда **ВОЗ** объявляет чрезвычайное положение, правительства во всём мире, вынуждены создавать запасы вакцины.

Список компаний, финансирующих *ESWI*, включает в себя следующие заинтересованные стороны: *Novartis* - дистрибьютор «Тамифлю», *Hofmann-La Roche*, *Baxter Vaccines*, *Med-Immune*, *GlaxoSmithKline*, *Sanofi Pasteur и другие*.

Не растерявшись в этот момент, ведущий мировой вирусолог, официальный советник по H_1N_1 правительств Великобритании и Голландии доктор Альберт Остерхаус глава Отдела Вирусологии в Медицинском центре Эразмуса Роттердама, также участвующий в программе ВОЗ «Глобальное старение и здоровье взрослых» и одновременно занимавший пост в спонсируемом фармацевтической промышленностью *ESWI*, который, в свою очередь, убеждал мир предпринять решительные шаги против серьёзной опасности новой Пандемии, которая, как они настаивали, могла конкурировать с ужасающей пандемией «испанки» 1918 года.

Банк с Уолл-Стрита **JP Morgan** оценивал, что в значительной степени в результате решения **ВОЗ** о пандемии, гигантские фармацевтические фирмы, которые также финансируют работу *ESWI* Остерхауса, поднялись приблизительно от 7,5€ до €10 миллиардов прибыли[14].

Таким же участником программы **ВОЗ** «Глобальное старение и здоровье взрослых» является доктор **Фредерик Хайден** (*Frederick Hayden*) из британского *Wellcome Trust* и, по сообщениям, близкий приятель Остерхауса. Хайден также получает деньги за «консультативные» услуги от *Roche* и *GlaxoSmithKline* среди прочих фармацевтических гигантов, вовлечённых в производство продуктов, связанных с паникой H_1N_1.

Председателем программы **ВОЗ** «Глобальное старение и здоровье взрослых» является другой британский учёный, профессор **Дэвид Солсбери** (*David Salisbury*) из британского Министерства здравоохранения. Он также возглавляет Консультативную группу **ВОЗ** по H_1N_1.

Солсбери - стойкий защитник фармацевтической промышленности. Он был обвинён британской гражданской группой по здравоохранению *One Click* в скрытии доказанных связей между вакцинами и взрывным ростом младенческого аутизма, а также связей между вакциной *Gardasil* и параличом и даже смертельными случаями.[15]

Тогда 28 сентября 2009 года тот же самый Солсбери заявил: «Есть очень ясное представление в научном сообществе, что нет никакого риска от включения *Thiomersal*...» Вакцина, используемая для H_1N_1 в Великобритании, прежде всего, производится *GlaxoSmithKlilne*. Она содержит ртутный консервант *Thiomersol*.

Из-за растущих свидетельств о том, что *Thiomersol* в вакцинах мог бы быть связан с детским аутизмом в Соединённых Штатах в 1999 году американская Академия Педиатрии и американская публичная служба здравоохранения призывали, чтобы этот компонент был удалён из вакцин.[16]

Ещё один участник программы **ВОЗ** «Глобальное старение и здоровье взрослых» с тесными финансовыми связями с производителям вакцин, которые извлекают выгоду от рекомендаций **ВОЗ**, - доктор **Арнольд Монто** (*Arnold Monto*), платный консультант производителей вакцины *MedImmune* - *Glaxo* и *ViroPharma*.

Более того, встречи «независимых» учёных Программы посещаются «наблюдателями», среди которых, да-да!, те самые производители вакцины *GlaxoSmithKline*, *Novartis*, *Baxter* и компания.

Можно спросить, если предполагается, что программа **ВОЗ** «Глобальное старение и здоровье взрослых» является ведущим экспертом в мире по гриппу и вакцинам, почему же они приглашают производителей вакцин заседать вместе с ними?

В прошлое десятилетие **ВОЗ**, чтобы повысить фонды в своём распоряжении, вступила в то, что называют *«public private partnerships»*. Вместо того, чтобы получать свои фонды исключительно от правительств-членов Организации Объединённых Наций, как заложено в его оригинальной идее, **ВОЗ** сегодня получает почти двойной свой обычный бюджет ООН в форме грантов и финансовой поддержки от частной промышленности.

Промышленность? Те же самые изготовители препаратов и вакцин, которые извлекают выгоду из решений, подобных объявленной в июне 2009 года пандемии H_1N_1. Как основные спонсоры бюрократов **ВОЗ**, естественно, фармамафия и её друзья имеют то, что называют «тёплым приёмом и открытыми дверями» в Женеве.[17]

В интервью журналу *Der Spiegel* в Германии эпидемиолог доктор **Том Джефферсон** (*Tom Jefferson*) из *Cochrane Collaboration*, организация независимых учёных, оценивающих все связанные с гриппом исследования, отметил значение приватизации **ВОЗ** и коммерциализации здоровья:

«...одна из экстраординарных особенностей этого гриппа - и всей саги гриппа - то, что есть некоторые люди, которые год за годом делают предсказания, и они всё хуже и хуже. Ни одно из этих предсказаний пока не сбылось, но эти люди всё ещё там делают эти предсказания. Например, что случилось с птичьим гриппом, который, как предполагалось, убил нас всех?

Ничего. Но это не останавливает этих людей от вечного создания их предсказаний. Иногда Вы чувствуете, что есть целая промышленность в ожидании пандемии...»

SPIEGEL: Кого Вы имеете в виду? ВОЗ?

Джефферсон: **ВОЗ** и чиновников здравоохранения, вирусологов и фармацевтические компании. Они построили эту машину вокруг нависшей пандемии. И вовлечено много денег, и влияний, и карьер, и целых учреждений! И всё, что требовалось, чтобы один из этих вирусов гриппа видоизменился, чтобы запустить эту машину перемалывать...».[18]

На вопрос, преднамеренно ли **ВОЗ** объявила пандемию, чтобы создать огромный рынок для вакцин H_1N_1 и препаратов, Джефферсон ответил:

«Не думаете ли Вы, что существует кое-что примечательное в том факте, что **ВОЗ** изменила своё определение пандемии? В старом определении был новый вирус, который начал быстро распространяться, от которого Вы не имеете иммунитета, и который создал высокую заболеваемость и смертность. Теперь последние два пункта изъяты, и таким образом свиной грипп был категоризирован как пандемия».[19]

Достаточно удобно, что **ВОЗ** выпустила это новое определение пандемии в апреле 2009 года, как раз вовремя, чтобы позволить **ВОЗ**, по совету программы «Глобальное старение и здоровье взрослых» и других, подобных Альберту «доктору Гриппу» Остерхаусу и Дэвиду Солисбери, объявить умеренные случаи гриппа «тип А» H_1N_1 всеобщей пандемией.[20]

В соответствующей сноске *Washington Post* 8 декабря в статье относительно серьёзности или отсутствии мировой «пандемии» H_1N_1 сообщил, что «со второй волной инфекции H_1N_1, накатившей на Соединённые Штаты, ведущие эпидемиологи предсказывают, что пандемия могла закончиться тем, что займёт место весьма умеренное с того момента, как современная медицина начала документировать вспышки гриппа».[21]

Российский парламентарий и председатель думского Комитета по здравоохранению **Игорь Баринов** обратился к российскому представителю в **ВОЗ** в Женеве с просьбой начать официальное расследование растущих свидетельств массовой коррупции в **ВОЗ** из-за тесного сотрудничества с фармацевтической промышленностью.

«Имеют место серьёзные обвинения в коррупции внутри **ВОЗ**», - сказал Баринов. - «Срочно необходима международная комиссия по расследованию».[22]

F. William Engdahl

OMS: le «pape de la grippe A» accusé de corruption

Voltairenet, 16 Décembre 2009
Version française: Nathalie Krieg pour Voltairenet
https://web.archive.org/web/20091228104431/www.voltairenet.org/article163315.html

On le surnomme «Dr Flu» (Docteur Grippe), le professeur Albert Osterhaus est le principal conseiller de l'Organisation mondiale de la Santé face à la pandémie de grippe H1N1. Depuis plusieurs années, il prédit l'imminence d'une pandémie globale et ce qui se passe aujourd'hui semble lui donner raison.

Cependant, le scandale qui a éclaté aux Pays-Bas et fait l'objet d'un débat au Parlement a mis en évidence ses liens personnels avec les laboratoires fabriquant les vaccins qu'il fait prescrire par l'OMS.

F. William Engdhal relate comment un expert peu scrupuleux a pu manipuler l'opinion publique internationale, surévaluer l'impact de la grippe H1N1, et faire la fortune des laboratoires qui l'emploient.

Dans le courant de cette année, le Parlement néerlandais [1] nourrissait des soupçons à l'encontre du fameux Dr Osterhaus et avait ouvert une enquête pour conflit d'intérêts et malversations. Hors des Pays-Bas et des médias néerlandais, seules quelques lignes dans la très respectée revue britannique *Science* firent mention de l'enquête sensationnelle sur les affaires d'Osterhaus.

Ni les références, ni l'expertise d'Osterhaus dans son domaine n'étaient remises en question. Ce qui est mis en cause, comme nous l'apprend la revue *Science* dans une simple dépêche, c'est l'indépendance de son jugement personnel en matière de pandémie de grippe A. *Science* publiait ces quelques lignes à propos d'Osterhaus dans son édition du 16 octobre 2009:

«Aux Pays-Bas, ces six derniers mois, il était difficile d'allumer sa télévision sans voir apparaître le célèbre chasseur de virus Albert Osterhaus et l'entendre parler de la pandémie de grippe A. Du moins, c'est ce que l'on croyait. Monsieur Grippe, c'était Osterhaus, le directeur d'un laboratoire de réputation internationale au sein du Centre médical de l'Université Érasme de Rotterdam. Mais, la semaine dernière, sa réputation est descendue en flamme après que des soupçons ont été émis sur sa velléité d'attiser les craintes d'une pandémie dans le but de servir les intérêts de son propre laboratoire dans la mise au point de nouveaux vaccins. Au moment où Science *mettait sous presse, la Deuxième Chambre du Parlement néerlandais annonçait même que la question serait débattue en urgence.»* [2]

Le 3 novembre 2009, sans pour autant en sortir indemne, Osterhaus avait su éviter les dégâts. Sur le site de *Science*, on pouvait lire dans l'un des blogs : *«La Deuxième Chambre du Parlement néerlandais a aujourd'hui rejeté une motion exigeant que le gouvernement rompe tout lien avec le virologiste Albert Osterhaus du Centre médical de l'Université Erasmus de Rotterdam, qui fait l'objet d'une mise en accusation pour conflit d'intérêts en tant que conseiller gouvernemental. De son côté, le Ministre de la Santé Ab Klink annonçait dans le même temps une loi* [3] *pour la transparence du financement de la recherche, contraignant les scientifiques à révéler les liens financiers qu'ils entretiennent avec des entreprises privées.»* [4]

Dans un communiqué sur le site Internet du Ministère de la Santé, M. Klink, dont on sait qu'il compte parmi les amis personnels d'Osterhaus [5], affirmait par la suite que ce dernier n'était qu'un conseiller du Ministère parmi de nombreux autres sur les questions des vaccins contre la grippe A H1N1. Il s'est aussi dit *« au courant »* des intérêts financiers d'Osterhaus [6]: ils ne cachent rien d'extraordinaire, simplement le progrès de la science et de la santé publique. Du moins, c'est ce qu'on croyait.

Un examen plus poussé du dossier Osterhaus laisse entrevoir que ce virologiste néerlandais à la renommée internationale pourrait se trouver au centre d'une arnaque mettant en jeu plusieurs milliards d'euros autour de l'idée d'une pandémie. Un système frauduleux dans lequel des vaccins non-testés sont injectés à des humains, au risque – cela c'est déjà produit – de provoquer de sévères séquelles, de graves paralysies, voire des décès.

La supercherie des fèces d'oiseau

Albert Osterhaus n'est pas du menu fretin. Il a joué un rôle dans toutes les grandes paniques suscitées par l'apparition de virus, depuis les mystérieux décès imputés au SRAS (Syndrome respiratoire aigu sévère) à Hong-Kong, là où l'actuelle Directrice générale de l'OMS Margaret Chan avait lancé sa carrière de responsable de la Santé Publique au niveau local. D'après sa biographie officielle à la Commission Européenne, en avril 2003, au paroxysme de la panique provoquée par le SRAS, Osterhaus fut engagé pour participer aux enquêtes sur les cas d'infections respiratoires qui se multipliaient alors à Hong Kong. On peut lire ces mots dans le rapport de l'Union Européenne: *«il démontra à nouveau son talent à réagir rapidement à de graves situations. En trois semaines, il a prouvé que cette maladie est provoquée par un coronavirus récemment découvert qui contamine les civettes, les chauves-souris et d'autres animaux carnivores.»* [7]

Par la suite, quand les cas de SRAS ne firent plus parler d'eux, Osterhaus passa à autre chose, œuvrant cette fois pour la médiatisation des dangers de ce qu'il nommait la grippe aviaire H5N1. En 1997 il avait déjà sonné l'alarme après la mort, à Hong Kong, d'un enfant de trois ans qu'Osterhaus savait avoir été en contact avec des oiseaux. Osterhaus développa son lobbying à travers les Pays-Bas et l'Europe, affirmant qu'une nouvelle mutation létale de la grippe aviaire s'était transmise aux humains et que des mesures drastiques devaient être prises. Il revendiquait être le premier scientifique au monde à avoir montré que le virus H5N1 pouvait contaminer des humains. [8]

Evoquant la dangerosité de la grippe aviaire dans une interview diffusée sur la BBC en octobre 2005, Osterhaus déclarait: *«si le virus réussissait effectivement à muter de telle sorte qu'il se transmette ensuite entre humains, alors nous serions dans une situation complètement différente: nous pourrions nous trouver devant un début de pandémie.»* .Il ajoutait: *«il y a un vrai risque que le virus soit disséminé par les oiseaux dans toute l'Europe. C'est un risque réel que personne n'a pourtant pu évaluer jusqu'à présent, parce que nous n'avons pas mené les expérimentations.»* [9] Le virus n'a jamais réussi sa mutation, mais Osterhaus était prêt à *«mener des expérimentations»* que l'on peut imaginer largement rétribuées.

Pour appuyer son alarmant scénario de pandémie en tentant de lui donner une légitimité scientifique, Osterhaus et ses assistants en poste à Rotterdam commencèrent à collecter et congeler des échantillons de fèces d'oiseaux. Il affirma que, selon les périodes de l'année, jusqu'à 30 % de tous les oiseaux d'Europe s'avéraient transporter le virus mortel de la grippe aviaire H5N1. Il affirma également que les éleveurs en contact avec des poules et des poulets se trouvaient alors exposés au dit virus. Osterhaus briefa les journalistes qui prirent bonne note de son message alarmiste. La classe politique fut mise en alerte. Dans la presse, il émit l'hypothèse selon laquelle le virus, qu'il étiquetait H5N1, après avoir provoqué plusieurs décès aux antipodes asiatiques, allait se propager en Europe, vraisemblablement transporté sur les plumes ou dans les entrailles d'oiseaux mortellement infectés. Il soutenait la thèse d'oiseaux migrateurs capables d'apporter le nouveau virus mortel vers l'ouest aussi loin qu'en Ukraine et sur l'île de Rügen [10]. Il lui suffit pour cela de feindre d'ignorer que les oiseaux ne migrent pas d'est en ouest mais bien du nord vers le sud.

La campagne alarmiste d'Osterhaus autour de la grippe aviaire décolla réellement en 2003, lorsqu'un vétérinaire néerlandais trouva la mort après avoir été malade. Osterhaus annonça que sa mort résultait d'une contamination par le virus H5N1. Il convainquit le Parlement néerlandais d'exiger l'abattage de millions de poulets. Pourtant, aucune autre personne ne succomba à une infection similaire à celle attribuée au H5N1. Pour Osterhaus, cela démontrait l'efficacité de la campagne d'abattage préventif. [11]

Pour Osterhaus, les déjections aviaires propageaient le virus en retombant sur les populations et les autres oiseaux au sol. Il était ferme dans sa conviction que ces déjections constituaient le vecteur de propagation de la nouvelle poussée mortelle du virus H5N1 depuis l'Asie.

Un problème se posait cependant avec le stock grandissant d'échantillons congelés des déjections aviaires que lui et ses associés avaient rassemblés et conservés dans son institut. La présence du virus H5N1 ne put être confirmée dans un seul de ces échantillons. En 2006, à l'occasion du congrès de l'OIE (Office international des épizooties, désormais appelé Organisation mondiale de la santé animale), Osterhaus et ses collègues à l'Université Érasme furent forcés d'admettre qu'en testant les 100 000 échantillons de matières fécales rassemblés avec tant de précaution, ils n'avaient découvert aucune trace du virus H5N1. [12]

En 2008, à Vérone, lors de la conférence de l'OMS intitulée « La grippe aviaire à l'interface Homme-Animal », Osterhaus prenait la parole devant ses collègues scientifiques, sans doute moins échauffés que le public non-scientifique par ses incitations à l'émotivité. Il admettait que: *«dans l'état actuel des connaissances, rien ne permet[tait] de formuler une mise en garde contre le virus H5N1, ni d'affirmer qu'il puisse provoquer une pandémie.»* [13] Mais, à ce moment-là, son regard se portait déjà fixement sur d'autres gâchettes à actionner pour faire converger son travail sur les vaccins avec de nouvelles possibilités de crise pandémique.

Grippe A et corruption à l'OMS

Constatant que la grippe aviaire n'avait fait surgir aucune vague meurtrière de grande ampleur – et après que Roche, qui produit le Tamiflu, et GlaxoSmithKline, qui produit le Relenza, eurent encaissé des milliards de dollars de profits quand les gouvernement ont décidé de stocker des vaccins antiviraux contestés –, Osterhaus et les autres conseillers pour l'OMS se tournèrent vers de plus verts pâturages.

En avril 2009, leurs recherches semblaient couronnées de succès lorsqu'à La Gloria, un petit village mexicain de l'État du Veracruz, un enfant malade fut diagnostiqué comme porteur de la grippe alors dite «porcine» ou H1N1. Avec un empressement déplacé, l'appareil propagandiste de l'Organisation mondiale de la Santé à Genève fut lancé sur les chapeaux de roues avec les déclarations de son Directeur Général, le Docteur Margaret Chan, concernant l'éventuelle menace d'une pandémie mondiale.

Mme Chan évoqua *«l'urgence de santé publique d'envergure internationale»* [14] Par la suite, d'autres cas déclarés à La Gloria furent présentés sur un site Internet médical comme: une «étrange» poussée d'infections pulmonaires et respiratoires aiguës, qui évoluent en broncho-pneumonie dans certains cas rencontrés chez des enfants. Un habitant du village en décrivait les symptômes: *«fièvres, toux sévères et sécrétions nasales très importantes»* [15]

Ces symptômes prennent par contre tout leur sens dans le contexte environnemental de La Gloria, une des zones au monde qui concentrent le plus grand nombre de porcs en élevage intensif, dont les exploitations sont principalement détenues par l'américain Smithfield. Depuis des mois, la population locale manifestait devant le siège mexicain du groupe Smithfield, se plaignant de graves affections respiratoires dues aux lisiers de porc. Cette cause plausible pour les diverses maladies diagnostiquées à La Gloria ne sembla intéresser ni Osterhaus ni les autres conseillers de l'OMS. Enfin se profilait la pandémie tant attendue, celle qu'il avait prédite dès 2003, lors de sa participation aux recherches sur le SRAS dans la province de Guandgong en Chine.

Le 11 juin 2009, Margaret Chan annonçait que la propagation du virus de la grippe H1N1 avait atteint le niveau 6 de l'«urgence pandémique ». Curieusement, elle précisait lors de cette annonce que *selon les informations disponibles à ce jour, une majorité écrasante de patients ressentent des symptômes bénins; leur rétablissement est rapide et complet, le plus souvent en ne recourant à aucun traitement médical.»* Avant d'ajouter: *«Au niveau mondial, le nombre de décès est peu important, nous ne nous attendons pas à voir une poussée soudaine et spectaculaire du nombre des infections graves ou mortelles.»*

On apprenait plus tard que Chan avait agi à la suite de débats fiévreux à l'OMS, sur les conseils du Groupe stratégique consultatif d'experts de l'OMS (SAGE, Strategic Advisory Group of Experts). L'un des membres du SAGE, à l'époque et encore aujourd'hui, est notre «Monsieur Grippe», le docteur Albert Osterhaus.

Osterhaus occupait non seulement une position stratégique pour recommander à l'OMS de déclarer l'«urgence pandémique » et inciter à la panique, mais il était aussi le président d'une organisation en première ligne sur le sujet, le Groupe de travail scientifique européen sur la grippe (ESWI, European Scientific Working group on Influenza), qui se définit comme un *«groupe multidisciplinaire de leaders d'opinion sur la grippe, dont le but est de lutter contre les répercussions d'une épidémie ou d'une pandémie grippales»* Comme ses membres l'expliquent eux-mêmes, l'ESWI mené par Osterhaus est le pivot central *«entre l'OMS à Genève, l'Institut Robert Koch à Berlin et l'Université du Connecticut aux États-Unis.»*

Le plus significatif au sujet de l'ESWI est que son travail est entièrement financé par les mêmes laboratoires pharmaceutiques qui gagnent des milliards grâce à l'urgence pandémique, tandis que les annonces faites par l'OMS obligent les gouvernements du monde entier à acheter et stocker des vaccins. L'ESWI reçoit des financements des fabricants et des distributeurs de vaccins contre le H1N1, tels que Baxter Vaccins, MedImmune, GlaxoSmithKline, Sanofi Pasteur et d'autres, dont Novartis, qui produit le vaccin et le distributeur du Tamiflu, Hofmann-La Roche.

Pour garder l'avantage, Albert Osterhaus, le plus grand virologiste mondial, conseiller officiel sur le virus H1N1 des gouvernements britannique et néerlandais et chef du Département de Virologie du Centre médical de l'Université Érasme, siégeait à la fois parmi l'élite de l'OMS réunie dans le groupe SAGE et présidait l'ESWI, parrainé par l'industrie pharmaceutique. À son tour, l'ESWI recommanda des mesures extraordinaires pour vacciner le monde entier, considérant comme élevé le risque d'une nouvelle pandémie qui, disait-on avec insistance, pourrait être comparable à l'effrayante pandémie de grippe espagnole de 1918.

La banque JP Morgan, présente à Wall Street, estimait que, principalement grâce à l'alerte pandémique lancée par l'OMS, les grands industriels pharmaceutiques, qui financent également le travail de l'ESWI d'Osterhaus, étaient prêts à engranger 7,5 à 10 milliards de dollars de bénéfices. [16]

Le docteur Frederick Hayden est à la fois membre du SAGE à l'OMS et du Wellcome Trust à Londres; il compte notamment parmi les proches amis d'Osterhaus. Au titre de services «consultatifs», Hayden reçoit par ailleurs des fonds de la part de Roche et de GlaxoSmithKline parmi d'autres géants pharmaceutiques engagés dans la production de produits liés à la crise du H1N1.

Un autre scientifique britannique, le professeur David Salisbury, qui dépend du ministère britannique de la Santé, est à la tête du SAGE à l'OMS. Il dirige également le Groupe consultatif sur le H1N1 à l'OMS. Salisbury est un fervent défenseur de l'industrie pharmaceutique. Au Royaume-Uni, le groupe de défense de la santé One Click l'a accusé de dissimuler la corrélation avérée entre les vaccins et la montée en flèche de l'autisme chez l'enfant, ainsi que celle existant entre le vaccin Gardasil et des cas de paralysie et même de décès. [17]

Le 28 septembre 2009, le même Salisbury déclarait: *«la communauté scientifique s'accorde sur l'absence totale de risque concernant l'inoculation du Thimérosal (ou Thiomersal).»* Ce vaccin, utilisé contre le H1N1 en Grande-Bretagne, est principalement produit par GlaxoSmithKlilne. Il

contient du Thimérosal, un conservateur à base de mercure. En 1999, de plus en plus de preuves faisant état que le Thimérosal présent dans les vaccins pourrait être la cause de cas d'autisme chez l'enfant aux États-Unis, l'American Academy of Pediatrics (Académie américaine de pédiatrie) et le Public Health Service (Bureau de la santé publique) avaient exigé son retrait de la composition des vaccins. [18]

On trouve encore un autre membre de l'OMS partageant d'étroits liens financiers avec les fabricants de vaccins qui profitent des recommandations du SAGE, en la personne du docteur Arnold Monto, un consultant rémunéré par les fabricants de vaccins MedImmune, Glaxo et ViroPharma.

Pire encore, participent aux réunions de scientifiques « indépendants » du SAGE, des «observateurs» comprenant, et oui, les mêmes producteurs de vaccins GlaxoSmithKline, Novartis, Baxter et consort. On peut se demander, si les meilleurs experts de la grippe au monde sont censés composer le SAGE, pourquoi invitent-ils les fabricants de vaccins à y participer?

Au cours de la dernière décennie, l'OMS mettait en place ce que l'on nomme des «partenariats public/privé», dans le but d'accroître les fonds à sa disposition. Mais, plutôt que de recevoir des fonds provenant uniquement des gouvernements des pays membres de l'ONU, comme cela était prévu à l'origine, l'OMS reçoit à l'heure actuelle de la part des entreprises privées près du double du budget habituellement alloué par l'ONU sous forme de bourses et d'aides financières. De quelles entreprises privées ? Des mêmes fabricants de vaccins et de médicaments qui profitent des décisions officielles telles que celle prise en juin 2009 à propos de l'urgence pandémique de la grippe H1N1. Tout comme les bienfaiteurs de l'OMS, les grands laboratoires ont tout naturellement leurs entrées à Genève, et ont droit à un traitement fait de *«portes ouvertes et de tapis rouges»* [19].

Dans une interview donnée au magazine allemand *Der Spiegel*, un membre de la Cochrane Collaboration, une organisation de scientifiques indépendants qui évaluent toutes les études menées sur la grippe, l'épidémiologiste Tom Jefferson montrait les conséquences de la privatisation de l'OMS et la marchandisation de la santé.

*«*T. Jefferson: […] *l'une des caractéristiques les plus ahurissantes de cette grippe, et de tout le roman-feuilleton qui en a découlé, est que, année après année, des gens émettent des prévisions de plus en plus pessimistes. Jusqu'à présent, aucune ne s'est jamais réalisée et ces personnes sont toujours là à répéter leurs prédictions. Par exemple, qu'est-il arrivé avec la grippe aviaire qui était censée tous nous tuer? Rien. Mais, ce n'est pas cela qui arrête ces gens de faire leurs prédictions. Parfois, on a le sentiment que c'est toute une industrie qui se prête à espérer une pandémie.*

Der Spiegel: *De qui parlez-vous? De l'OMS?*

T. J: L'OMS *et les responsables de la santé publique, les virologistes et les laboratoires pharmaceutiques. Ils ont construit tout un système autour de l'imminence de la pandémie. Beaucoup d'argent est en jeu, ainsi que des réseaux d'influence, des carrières et des institutions tout entières! Et il a suffit qu'un des virus de la grippe mute pour voir toute la machine se mettre en branle.»* [20]

Lorsqu'on lui a demandé si l'OMS avait délibérément déclaré l'urgence pandémique dans le but de créer un immense marché pour les vaccins et les médicaments contre le H1N1, Jefferson a répondu:

«Ne trouvez-vous pas frappant que l'OMS ait modifié sa définition de la pandémie ? L'ancienne définition parlait d'un virus nouveau, à propagation rapide, pour lequel l'immunité n'existe pas, et qui entraîne un taux élevé de malades et de décès. Aujourd'hui, ces deux derniers points sur les taux d'infection ont été supprimés, et c'est ainsi que la grippe A est entrée dans la catégorie des pandémies.» [21]

Très judicieusement, l'OMS publiait en avril 2009 la nouvelle définition de la pandémie, juste à temps pour permettre à l'OMS, sur les conseils émanant, entre autres, du SAGE, de «Monsieur Grippe», alias Albert Osterhaus, et de David Salisbury, de qualifier d'urgence pandémique des cas bénins de grippe, rebaptisée grippe A H1N1. [22]

Le 8 décembre 2009, dans la note en bas de page pertinente d'un article sur la gravité ou la bénignité de la «pandémie mondiale » du H1N1, le *Washington Post* mentionnait que: *«la deuxième vague d'infection du H1N1 étant parvenue à son apogée aux États-Unis, les principaux épidémiologistes prévoient que la pandémie pourrait compter parmi les plus bénignes depuis que la médecine moderne documente les épidémies de grippe.»* [23]

Igor Barinov, parlementaire russe et président du Comité pour la Santé à la Douma, a exigé des représentants russes à l'OMS en poste à Genève qu'ils diligentent une enquête officielle sur les indices multiples de la corruption massive acceptée par l'OMS et menée par l'industrie pharmaceutique. *«De graves accusations de corruption sont prononcées à l'encontre de l'OMS»*, affirmait Barinov. *«Une commission internationale d'enquête doit s'organiser au plus vite.»* [24]

Big Pharma inside the WHO:
confidential analysis of unreleased WHO Expert Working Group draft reports

WikiLeaks, 8 December 2009
https://wikileaks.org/wiki/Big_Pharma_inside_the_WHO:_confidential_analysis_of_unreleased_WHO_Expert_Working_Group_draft_reports%2C_8_Dec_2009

Release date: December 9, 2009

Summary

This is a confidential pharmaceutical industry trade association dossier about the WHO Expert Working Group (EWG) on R&D Financing.

The International Federation of Pharmaceutical Manufacturers & Associations (IFPMA; "Big Pharma") gave its members 4 documents: a non-public draft report of the WHO EWG and a non-public Comparative Analysis done by the working group, the IFPMA Overview of the EWG Comparative Analysis, and IFPMA summary slide on the EWG Draft Report.

The compilation of documents shows the influence of "Big Pharma" on the policy making decisions of the WHO, the UN body safeguarding public health. These confidential documents were obtained by the drug industry before their public release to WHO member states (scheduled to be released May 2010). The document also illustrates that the WHO expert group was highly responsive to industry lobbying – a result that public health groups had feared since early 2009, when the expert group met with the industry, but refused to meet with public health groups known to be industry critics.

The likely audience for these documents include countries, public health policy makers, civil society, industry, academia, media, patients and the general public.

Journalists can contact Dr Margaret Chan, Director-General of WHO: chanm@who.int and Malebona Precious Matsoso, WHO Director, Public Health, Innovation and Intellectual Property: matsosom@who.int

According to our source, the English version of the final report of the EWG with its recommendations is expected to be released to member state countries this week.

Tør vi stole på WHO?
Do we dare to trust the WHO?

Information, 12 december 2009
https://www.information.dk/debat/leder/2009/12/toer-stole-paa-who?lst_cntrb

Man ved fra talrige videnskabelige undersøgelser, at det giver uheldige beslutninger, når der sidder folk med interessekonflikter i de rådgivende udvalg. Og mistanken om, at der foregår ubehagelige ting, stiger markant, når man tilmed ikke ved, hvad der foregår. Peter Gøtzsche, forskningsleder i Cochrane Centeret

I Finland sidder en statsansat forsker med et problem. Det begyndte ellers godt. I år fik professor Juhani Eskolas vaccineforskningsprogram 47 millioner kroner til at forske i pneumokokvaccine af vaccineproducenten GlaxoSmithKline. Det største enkeltstående bidrag professorens institut har modtaget i 2009. Men så kom pressen, og så kom den finske sundhedsminister med løftede pegefingre, og nu sidder den finske professor pludselig i en national interessekonflikt. Juhani Eskola er nemlig også vaccinerådgiver for WHO's såkaldte SAGE-gruppe. Og så betyder det noget, når man får 47 millioner kroner af industrien. Og man ikke oplyser om det.

Siden november har Information beskrevet syv WHO-eksperter, der enten har bijob som konsulenter for medicinalindustrien eller får finansieret deres forskning af medicinalindustrien. Samme eksperter, der vejledte WHO's generalsekretær Margaret Chan, da hun 11. juni i år erklærede, at verden stod midt i en H1N1-pandemi. Fra det sekund trådte en lang række hvilende kontrakter mellem medlemslande og medicinalvirksomheder i kraft. Produktionen af vacciner til 55 milliarder kroner gik i gang. Men når den, der råber alarm, har økonomiske interesser i nødberedskabet, bør offentligheden vide det.

Intet menneske er upåvirkeligt. Heller ikke forskere, der siger, de er det. Tværtimod viser talrige undersøgelser, at forskere, læger og sundhedspersonale påvirkes af medicinalvirksomheders indflydelse. Ifølge Glasgow University's Robertson Centre for Biostatistics bruger medicinalindustrien gennemsnitligt 800.000 kroner om året på direkte markedsføring pr. læge. Derfor appellerer den internationale ngo, NoFreeLunch, til alle i sundhedsvæsenet om at aflægge et troværdighedsløfte for at modstå medicinalindustriens omfattende markedsføring. Når markedsføring går fra at være en reklamekop eller en golftur til at være 47 millioner kroner til instituttet, man arbejder for, må det kræve sin mand at modstå de budskaber, der følger med beløbet fra GlaxoSmithKline.

Da GlaxoSmithKline i dag er leverandør af vaccinen Pandemrix til den finske befolkning, har historien om de hemmeligholdte millioner skabt furore i Finland. Der er ingen beviselig sammenhæng mellem GlaxoSmithKlines forskningsstøtte og valget af samme firma som leverandør af H1N1-vaccine. Men pointen er, at vi ikke kan vide det.

Dermed opstår det næste problem i kølvandet på den finske forskers interessekonflikter, nemlig manglen på åbenhed i WHO. I dag bringer Information historien om WHO's hemmelige rådgivnings-komite, den såkaldte Emergency Committee, hvor 18 medlemmers navne, baggrund og virke er komplet mørkelagt. Den hemmelige komité refererer direkte til generalsekretær Margaret Chan, og

derfor var de ligesom SAGE-gruppen med til at beslutte, hvornår pandemiberedskabet skulle træde i kraft. Ifølge WHO er komiteen hemmelig, fordi eksperterne ellers risikerer at komme under pres. Det skaber to nye problemer. For det første aner vi ikke, hvem der reelt rådgiver verdenssundhedens mest magtfulde person. For det andet er den logiske følge af det argument, at resten af WHO-grupperne må opleve at være under pres, når de træffer beslutninger.

Åbenhed er det demokratiske udgangspunkt for god forvaltningsskik. Offentligheden bør vide, hvordan de politiske beslutninger bliver til.

Man ved fra undersøgelser, at manglen på åbenhed er proportionel med et højt niveau af korruption. Og det er logisk, at befolkningens tillid til regeringer og offentlige institutioner daler i takt med afsløringer om korruption og hemmeligholdelse af informationer.

Den 7. April 1948 blev WHO oprettet for at sikre den internationale folkesundhed. WHO er skabt for at forhindre sygdom og redde liv, og al viden fra det internationale samfund, der kan bidrage til det formål, må være ønskelig. Men WHO's virke er afhængig af regeringers og befolkningers tillid til deres anbefalinger. Og tillid til at de mennesker, der er ansat i WHO, handler i folkesundhedens og kun folkesundhedens interesse.

Oplysninger der vedrører verdens borgeres liv og sundhed bør være frit tilgængelige, ligesom navne på alle interessenter, der påvirker WHO's beslutninger skal offentliggøres.

Den finske professors problem bliver til vores problem, indtil regeringer stiller krav om, at WHO er fuldt ud åbne om de eksperter, de har ansat, de beslutninger, der bliver truffet og de argumenter, der ligger bag beslutningerne.

Do we dare to trust the WHO?
Tør vi stole på WHO?

Information, 12 december 2009
https://www.information.dk/debat/leder/2009/12/toer-stole-paa-who?lst_cntrb
https://web.archive.org/web/20100102041654/http://theflucase.com/index.php?option=com_content&view=article&id=2348%3Ado-we-dare-to-trust-the-who-ask-danish-journalists&catid=41%3Ahighlighted-news&Itemid=105&lang=en

"It is well known from many scientific studies that unhappy decisions result when people with conflicts of interest are members of advisory groups. And the suspicion that unpleasant things are taking place right now grows when you don't even know what is going on."

Peter Goetzsche, research director at the Cochrane Center in Copenhagen.

In Finland, a problem concerning a researcher in a government position has grown after everything initially seemed fine.

This year Professor Juhani Eskola's vaccine research programme received 47 million crowns from the vaccine producer Glaxo SmithKline in order to develop a pneumococ vaccine.

It is the greatest singule contribution the professor's institute has received in 2009. But then along came the media, and next the Finnish Minister of Health with a raised index finger, and suddenly the Finnish professor is at the epicentre of a national conflict of interests.

The reason is that Juhani Eskola is in parallel vaccine consultant for WHO's so-called SAGE-group. And then it suddenly does matter if you receive 47 million crowns from the industry. Particularly when you keep quiet about it.

Since November "Information" has reported on how seven WHO experts either have an additional job as consultants for the industry or get their research financed by the pharmaceutical industry.

It was those same experts who were acting as advisors to the Director General of WHO, Margaret Chan, when she declared on June 11 of this year that the world was in the midst of a H1N1-pandemic.

From that moment several existing contracts between member countries and the pharmaceutical industry came into force. The production of vaccines for 55 billion crowns started. But when the figure who alerts the world has financial interests in the emergency the public has the right to know.

No human being is beyond being influenced. Not scientific researchers, who claim that they are, either. On the contrary, lots of studies have shown that researchers, medical doctors and health staff are indeed influenced by medical firms.

According to the Robertson Center for Biostatistics at Glasgow University, the pharmaceutical industry spends an average of 800.000 crowns a year on direct marketing for every single medical doctor.

For that reason the international NGO, NoFreeLunch, appeals to everybody employed in the healthcare sector to resist the extensive marketing of the pharma industry.

When the marketing develops from a propaganda cup or a golf watch to 47 million crowns donated to your own institute, one really has to be a strong person to resist the messages that accompany that amount of money from GlaxoSmithKline.

Because GlaxoSmithKline is the supplier of the vaccine Pandemrix to the Finnish population, the revelation about the secret millions has caused a scandal inside Finland.

There is no proven connection between the research funding from GlaxoSmithKline and the selection of that same company as the supplier of the H1N1 vaccine. But the point is we cannot know for sure.

The Finnish researcher's conflict of interests is part of a bigger problem, which also concerns the lack of transparency in WHO.

Today "Information" brings the report about WHO's secret consultation committee, the so-called Emergency Committee. The activities of ist 18 members take place in complete obscurity inside this forum. Not even their names or background are known to the public. This secret committee refers directly to Director General Margaret Chan and its members – just like the SAGE group – therefore, had a voice concerning when a pandemic emergency declaration should be made.

According to WHO the committee is secret because if it were not, there is a risk that the experts would be exposed to pressure.

This situation creates to new problems. First of all we don't know, who is really giving advice to the most powerful person in the WHO. Secondly the logic consequences of that argument is that all the other WHO groups must experience pressure when they make decisions.

Transparency is the democratic starting point for good administration. The public ought to know how political decisions come into force.

It is known from many studies that lack of openness is directly proportional to a high level of corruption. And it is logical that the population's trust in governments and public institutions sinks simultaneously with revealations of corruption and the repression of information.

WHO was established on April 7, 1948 in order to promote international public health. WHO has been created to prevent diseases and to save lives, and all knowledge from the international community which can contribute to this aim should be welcome.

But the functioning of the WHO is dependent on government's and population's being able to trust the institutions recommendations. And on a confidence that the people who are employed by the WHO are acting solely in the interests of public health.

Information concerning the life and health of the world citizens must be available to everybody, just like the names of all the parties who influence the decision making process inside the WHO need to be declared.

The Finnish professor's problem becomes our problem until governments demand that WHO becomes completely transparent concerning the experts it employs, the decisions it is making and the arguments behind the decisions.

THE FLU CASE

Louise Voller & Kristian Villese

WHO Adviser conceals a donation of millions from a pharmaceutical company

The Flu Case, 17 December 2009, 11:33
https://web.archive.org/web/20100102034318/http://theflucase.com/index.php?option=com_content&view=article&id=2309%3Awho-adviser-conceals-a-donation-of-millions-from-a-pharmaceutical-company-&catid=41%3Ahighlighted-news&Itemid=105&lang=en
from: Information, 12 December 2009

A Finnish member of the WHO board, an advisor on vaccines, has received 46 million crowns (6 million euros) for his research centre from the vaccine manufactures, GlaxoSmithKline. WHO promises transparency, but this conflict of interests is not available for the public to see at WHO's homepage.

Another 'WHO' vaccine advisor is withholding information concerning financial support from the pharmaceutical industry.

Professor Juhani Eskola is the director of the Finnish research vaccine programme (THL) and a new member of the WHO group, 'Strategic Advisory Group of Experts' (SAGE), which gives advice to the WHO Director-General, Margaret Chan. 'SAGE' also recommend which vaccines - and how many - member countries should purchase for the pandemic.

According to documents acquired through the Danish 'Freedom of Information Act,' Professor Juhani Eskola's Finnish institute, THL, received almost 6.3 million Euro from GlaxoSmithKline (GSK) for research on vaccines during 2009.

This amount of money qualifies GlaxoSmithKline as THL's main source of income. GlaxoSmith-Kline produces the H1N1-vaccine 'Pandemrix,' which the Finnish government following recom-mendations from THL and WHO purchased for a national pandemic reserve stockpile.

These facts bring Professor Juhani Eskola in line with several other 'WHO 'experts who play a double role by having financial ties to the pharmaceutical industry – a double role which notably is not published by WHO.

During November, the Danish daily, 'Information' has informed the public that several members of WHO's expert group have also been secretly working for the pharmaceutical industry. Since revealing this information, a record of meetings and the conflict of interests of some of the experts have become accessible, but not all, including Juhani Eskola.

Conflict of Interest

In Finland, Professor Juhani Eskola is at the centre of a national conflict of interest. The Finnish Minister of Health has become involved in this case and has asked for transparency concerning the researcher's financial ties to the pharmaceutical industry. However, Professor Eskola doesn't agree that there is a problem. He secures and protects his 'WHO' status, by offering a minor 'consultative payment' to the pharmaceutical company, 'Novartis.'

"Why haven't you informed the public about a research grant of six million Euros from GlaxoSmithKline?" Professor Eskola comments, "It is a contract my chief and GSK have made, and I am not a part of the study, which receives the money."

Regarding 'WHO's declaration on conflicts of interest, 'SAGE' experts are obliged to inform on all kinds of financial research support, scholarships, payment for collaboration and sponsor support for the research unit, during the past three years. "We have 1,400 researchers at 'THL' and if I declare every economic transaction I am a involved in then it gets complicated.

My interpretation of the WHO-declaration was that I didn't have to declare the agreement of collaboration with GSK, as I neither receive the money personally nor do my research team. 'WHO' has asked me, and now I wait to be informed, whether they agree with my interpretation. If they don't, they should make their declaration more clear."

You are chair of the department and during 2009, GSK is your greatest contributor. Don't you see a conflict of interests in this matter?

"It is a discussion we have had with the Finnish Minister of Health during the past few weeks but it is the ministry, who has bought the vaccines, not our institute. Pandemrix was chosen as the best vaccine and could be available soon at the Finnish market. The decision had to be made at the beginning of June and in my mind, the ministry of health chose the right solution, namely Pandemrix."

But do you recognize a conflict of interest? - "We are aware that there appears to be a conflict of interest" he says.

"Very Serious"

According to WHO, all SAGE-members are obliged to inform about all financial interests, inclusive financing from the pharmaceutical industry, consulting payments and other forms of professional employment. Meanwhile, WHO has rejected an invitation to be interviewed about why not all financial interests of the WH -experts has been declared.

But in a mail WHO spokesman Gregory Hartl writes as follows:

"WHO has recently learned, that the Finnish National Institute for Health and Welfare has a research contract with GSK. The contract concerns a research project about pneumococcal-vaccine in the Finnish vaccination programme. WHO will take suitable action according to everything, which must be considered as conflicts of interests in this case."

The Danish journalists have reported on other cases involving SAGE experts with financial links to pharmaceutical companies, many of which have not been declared.

Dr. Peter Figueroa, Professor, Public Health, Epidemiology & AIDS, Department of Community Health & Psychiatry, Faculty of Medical Sciences, University of the West Indies, Jamaica, received money from Merck.

Dr. Neil Ferguson has received funding Baxter, GlaxoSmithKline und Roche as well as insurance companies that he advised about pandemics but this was only revealed after publicity.

Professor Malik Peiris, Department of Microbiology, the University of Hong Kong, Faculty of Medicine, Hong Kong has received money from Baxter GSK und Sanofi Pasteur.This is not declared on the Who website.

Dr. Arnold Monto, advisor to Chiron, GlaxoSmithKline, MedImmune, Roche, Novartis, Baxter und Sanofi Pasteur.

Dr. Friedrich Hayden, consultant to MedImmune in 2006 and Sanofi Pasteur, in 2007. He has also got money from Roche, RW Johnson und SmithKline Beecham. The interests are not declared on WHO website.

Dr. Albert Osterhaus, head of the European Scientists Fighting Influenza, financed by Baxter, Crucell, Novartis, Hoffmann-La Roche, MedImmune, Nobilon, Sanofi Pasteur, MSD, GlaxoSmith Kline und Solvay.

In a new development, Finnish Ministry of Social and Welfare has authorized the National Institute of Health and Welfare (THL) to purchace another 5.3 million H1N1 pre-pandemic vaccines for the whole population of Finland, adding to the existing stockpile of 5.3 million H5N1 vaccines and a contract to purchase another 5.3 million vaccines.

Below is a correspondence with WHO on the conflict of interest of Eskola by a Finnish citizen, revealing staff of WHO scrambling to whitewash their failure to declare Eskola's conflict of interest:

Information

Louise Voller, Kristian Villesen

Hemmelig komité rådgiver WHO om svineinfluenza
WHO refuses to name members of secret Committee driving Vaccination Agenda

Information, 12 december 2009
https://www.information.dk/udland/2009/12/hemmelig-komite-raadgiver-who-svineinfluenza?lst_cntrb

Offentligheden må ikke vide, hvem der sidder i den gruppe, som rådgiver WHO om svineinfluenza. Gruppen stod bag beslutningen om at opgradere influenzaen fra epidemi til pandemi. Siden har medicinalvirksomhederne solgt for over 55 milliarder kroner af vaccinen.

WHO har en hemmelig gruppe af eksperter, som rådgiver om svineinfluenza – den såkaldte Emergency Committee. Komiteen er helt central og har blandt andet rådgivet generaldirektør Margaret Chan til at udnævne svineinfluenzaen til en pandemi. En opfordring, som hun – med henvisning til gruppen af eksperter - fulgte den 11. juni i år.

Det betød en enorm økonomisk gevinst for medicinalindustrien. Mange medlemslande - herunder Danmark - har nemlig kontrakter med de store medicinalvirksomheder og er derfor forpligtet til at købe vacciner, når WHO fastslår, at en virus er en pandemi. I alt vurderer investeringsbanken J.P. Morgan, at der siden beslutningen er købt vacciner og anden influenzamedicin for mere end 55 milliarder kroner.

Trods udvalgets store indflydelse og magt, kan offentligheden ikke få lov at se, hvem der sidder i komiteen - og derfor heller ikke, om gruppens medlemmer er betalt af medicinalindustrien. Den eneste information, offentligheden har tilgængelig, er, at komiteen består af 18 personer, som generaldirektøren har udvalgt fra WHO's ekspertliste. Og det er slet ikke åbenhed nok, mener lederen af det uafhængige forskningsinstitut, Cochrane, Peter Gøtzsche:

»Det hører ingen steder hjemme, at der sidder et hemmeligt udvalg, der skal rådgive WHO om så vigtig en sag. Der skal være fuldstændig åbenhed omkring, hvem de er, og hvilke interessekonflikter det måtte have. Ellers kan borgerne ikke have tillid til det, der foregår,« siger Peter Gøtzsche. Information har tidligere fortalt, at der i flere af WHO's rådgivende grupper sidder medlemmer, der er betalt af medicinalindustrien. Peter Gøtzsche frygter, at det også er tilfældet i Emergency Committee.

»Det udvalg har en enorm magt. Og vi ved ikke, om de mennesker, der sidder i det, modtager penge fra eller har aktier i de firmaer, der producerer vaccinerne,« siger Peter Gøtzsche.

Administrerende direktør i Sundhedsstyrelsen, Jesper Fisker, er enig:

»Det er kritisabelt, at man ikke kan se, hvem der sidder i udvalget og derfor heller ikke kan se, hvilke interesser der er repræsenteret. Det må være en del af den almindelige ambition om åbenhed og gennemsigtighed, at man kan se, hvilken rolle udvalget har, og hvem der sidder i det,« siger han og tilføjer: »Jo mere indflydelse et udvalg har, jo vigtigere er det, at der er åbenhed. Og hvis de har rådgivet i forhold til en vigtig beslutning - og det tyder det jo på er tilfældet - så er det ekstra vigtigt, at der er åbenhed. Det skal der simpelthen være.«

Utrygt

Peter Gøtzsche er langt fra tryg ved, at det det kun er ledelsen i WHO, der ved, hvem der sidder i udvalget:

»Hvorfor skulle medlemmerne ikke have interessekonflikter? Med det kendskab vi gennem den seneste tid har fået til WHO's brug af eksperter, så vil man da forvente at nogle af dem har interessekonflikter.«

I november kunne Information afsløre, at der i den officielle arbejdsgruppe, Strategic Advisory Group of Experts (SAGE), som rådgiver WHO om vacciner, sidder flere folk, der modtager honorarer eller forskningsstøtte fra medicinalindustrien. Siden har Svenska Dagbladet og Information fundet yderligere tre medlemmer af den faste rådgivningsgruppe, som er aflønnet af de vaccineproducerende virksomheder. Denne måde at konstruere en magtfuld organisation på er problematisk, mener Peter Gøtzsche:

»Man ved fra talrige videnskabelige undersøgelser, at det giver nogle uheldige beslutninger, når der sidder folk med interessekonflikter med i de rådgivende udvalg. Og mistanken om, at der foregår ubehagelige ting, stiger markant, når man tilmed ikke ved, hvad der foregår.«

WHO svarer ikke

WHO har trods talrige henvendelser over de seneste fire dage ikke ønsket at stille op til et interview med Information om den hemmelige komité. Men WHO-talsmand Gregory Härtl har over for Svenska Dagbladet fortalt følgende om komitéen:

»Navnene på medlemmerne i komitéen er hemmelige. Vi vil ikke have, at de skal kunne udsættes for noget pres udefra. De er valgt ud fra deres ekspertkundskaber inden for influenza, virusspredning og sygdomskontrol, siger Gregory Härtl.

- Hvilken form for pres risikerer medlemmerne at blive udsat for?

»Det kan jeg ikke komme ind på. Men det vigtige er, at medlemmerne i komiteen ikke behøver at tage hensyn til nogen eller noget udefra komiteen i deres rådgivning af WHO's generaldirektør.«

- Har nogen af medlemmerne i komiteen forbindelser til eller samarbejder med medicinal-industrien?

»Jeg ved ikke, hvem medlemmerne er. Men jeg tror, at de kontrolleres for koblinger til medicinalindustrien.«

- Bør WHO ikke være transparent, når det gælder beslutninger om sygdomme, som berør millioner af mennesker?

»I kampen mod denne epidemi må man samarbejde med mange parter. Det inkluderer regeringer, frivillige organisationer og medicinalindustrien. Vi må finde de bedste løsninger for at redde menneskers liv. At redde liv er det allervigtigste for os,« siger Gregory Härtl

WHO refuses to name members of secret Committee driving Vaccination Agenda
Hemmelig komité rådgiver WHO om svineinfluenza

Information, 12 december 2009
https://www.information.dk/udland/2009/12/hemmelig-komite-raadgiver-who-svineinfluenza?lst_cntrb
https://web.archive.org/web/20100102013016/http://theflucase.com/index.php?option=com_content&view=article&id=2338%3Awho-refuses-to-name-members-of-secret-committee-driving-vaccination-agenda&catid=41%3Ahighlighted-news&Itemid=105&lang=en

The names of the members of a group that acts as advisers to WHO on the swine flu are a closely kept secret.

The group advocated upgrading the status of the flu from epidemic to pandemic.

Since then, pharmaceutical companies have sold more than 55-billion crowns worth of vaccines, writes the Danish daily news outlet "Information".

WHO relies on a secret group of experts, the so-called Emergency Committee. The organisation consults this Emergency Committee on managing the swine flu.

The committee is at the epicentre of desicion-making and recommended the declaration of a swine flu pandemic to Director General, Margaret Chan.

A recommendation that she implemented on June 11th this year, referring to the group of experts.

This resulted in enormous economic gains for the pharmaceutical industry.

Many member countries – among them, Denmark – have contracts with the big pharma companies and are obliged to buy vaccines when WHO determines that a virus is a pandemic.

The investment bank J.P. Morgan estimates that vaccines and other types of flu medicine amounting to more than 55 billions of crowns have been sold since this declaration.

In spite of the committee's enormous influence and power, the public is not allowed to learn who the members of the committee actually are.

As a consequence, the public is also denied access to information needed to check whether the members of this group are on the payroll of the pharma industry.

The only information available to the public is that the committee consists of 18 people whom the Director General has selected from WHO's list of experts.

But such a level of transparency is inadequate according to Peter Goetzsche, who is the leader of the independent research institution, Cochrane, in Copenhagen.

"It is not acceptable that a secret committee gives advice to WHO in a matter of such importance. There needs to be complete transparency over who they are and what conflicts of interests the committee may have. If this is not the case, people cannot have confidence in what is going on," says Peter Goetzsche.

According to earlier information, WHO has members in it's groups of consultants who are on the payroll of the pharma industry.

Peter Goetzsche fears that this could also be the case with the Emergency Committee.

"That committee possesses enormous power. And yet we don't know whether those people who are sitting on it receive money from or have stocks in those firms which produce the vaccines," says Peter Goetzsche.

Managing director of Danish Board of Health, Jesper Fisker, agrees.

"It is unnacceptable that we cannot see who the members of the committee actually are and consequently cannot see what interests are represented. It has to be part of the common ambition of openness and transparency that we can see, what role the committee plays and who the members are," he says and adds: "The more influential a committee is, the more important it is, that there is transparency. And if they have given advice concerning an important decision – and that seems to be the case – then it is even more important that there is transparency. This simply has to happen."

Insecure

Peter Goetzsche's concerns are not eased by the fact that only the leadership of WHO has access to the names of the members of this committee.

"Why should the members not have conflicts of interest? In view of the knowledge we lately have acquired concerning WHO's use of experts, can expect that some of them have conflicts of interest".

In November, it was revealed that the official working group, Strategic Advisory Group of Experts (SAGE), which advices WHO about vaccines, comprised several members, who receive fees or research support from the pharmaceutical industry.

Since then the Swedish daily newspaper Svenska Dagbladet and Information have discovered another three members of this permanent group of consultants who are on the payroll of the companies manufacturing vaccines.

According to Peter Goetzsche, this approach in a powerful organisation is associated with difficulties.

"It is well known from lots of scientific studies that it generates unfortunate decisions when people with interests of conflict are members of advisory groups. And the suspicion that unpleasant things take place grows when you don't even know what is going on."

Who does not answer

In spite of several calls during the last four days WHO has not agreed on an interview on the secret committee.

But WHO-spokesman Gregory Hartl said the following about the committee to the Swedish daily Svenska Dagbladet.

"The names of the members of the committee are secret. We don't want them to be exposed to any kind of pressure from the outside. They have been selected on basis of their expertise and knowledge concerning influenza, the spreading of viruses and control of diseases, says Gregory Hartl.

What kind of pressure are the members risking exposure to?

"I cannot talk about that. But the important thing is, that the committee does not need to show consideration for anything or anybody outside the committee in their consultations with the Director General of WHO".

Have any of the members of the committee connections to or collaborate with the pharmaceutical industry?"

"I don't know who the members are. But I think they are controlled concerning ties to the industry."

Should WHO not be transparent concerning decisions affecting millions of people?

"In the fight against this epidemic you have to collaborate with many partners. That includes governments, non governmental organisations and the pharmaceutical industry. We must find the best solutions to save human lives. To save lives is of utmost importance to us" says Gregory Hartl.
